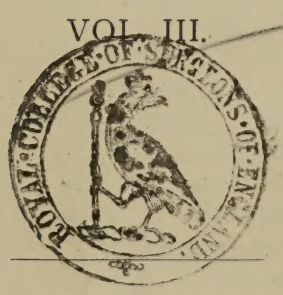
A WEEKLY JOURNAL

OF

MEDICAL AND SURGICAL SCIENCE.

VOL. III.



1872--73.

PHILADELPHIA:
J. B. LIPPINCOTT & CO.
1873.

Entered according to Act of Congress, in the year 1873, by
J. B. LIPPINCOTT & CO.,
In the Office of the Librarian of Congress at Washington.

LIPPINCOTT'S PRESS,
PHILADELPHIA.

CONTRIBUTORS TO VOL. III.

D. Hayes Agnew, M.D., Professor of Surgery, University of Pennsylvania.

E. P. Allen, M.D., Athens, Pennsylvania.

Harrison Allen, M.D., Professor of Comparative Anatomy, University of Pennsylvania.

O. H. Allis, M.D., Surgeon to the Presbyterian Hospital.

Wm. Ashbridge, M.D., Philadelphia.

S. Ashhurst, M.D., Surgeon to the Episcopal Hospital, Philadelphia.

Walter F. Atlee, M.D., Surgeon to St. Joseph's Hospital, Philadelphia.

Joseph R. Beck, M.D., Fort Wayne, Ind.

A. C. W. Beecher, M.D., Philadelphia.

R. M. Bertolet, M.D., Philadelphia.

J. Frazer Boughter, M.D., U.S.A.

John H. Brinton, M.D., Surgeon to the Philadelphia Hospital (Blockley).

Charles H. Burnett, M.D., Aural Surgeon to the Presbyterian Hospital, Philadelphia.

H. L. Byrd, M.D., Professor of Diseases of Women and Children in the College of Physicians and Surgeons, Baltimore.

A. S. Carroll, M.D., New York.

Richard A. Cleemann, M.D., Philadelphia.

J. Solis Cohen, M.D., Philadelphia.

W. G. Cotton, M.D., East Bethlehem, Pennsylvania.

H. Culbertson, M.D., Zanesville, Ohio.

R. G. Curtin, M.D., Philadelphia.

T. D. Davis, M.D., Philadelphia.

Louis A. Duhring, M.D., Physician to the Dispensary for Skin Diseases, Philadelphia.

G. Echeverria, M.D., Consulting Physician to the New York Hospital for Epileptics and Paralytics.

E. Eshleman, M.D., Philadelphia.

A. Frické, M.D., Philadelphia.

J. E. Garretson, M.D., Lecturer on Diseases of the Mouth and Jaws, University of Pennsylvania.

George S. Gerhard, M.D., Philadelphia.

F. H. Getchell, M.D., Clinical Lecturer on Diseases of Women and Children, Jefferson Medical College, Philadelphia.

W. H. H. Githens, M.D., Philadelphia.

William Goodell, M.D., Physician in Charge of the Preston Retreat, Philadelphia.

Samuel D. Gross, M.D., Professor of Surgery, Jefferson Medical College, Philadelphia.

H. B. Hare, M.D., Physician to the Episcopal Hospital, Philadelphia.

George C. Harlan, M.D., Surgeon to Wills Hospital, Philadelphia.

R. P. Harris, M.D., Philadelphia.

Henry Hartshorne, M.D., Philadelphia.

Francis L. Haynes, M.D., Philadelphia.

F. P. Henry, M.D., Philadelphia.

W. Hunt, M.D., Surgeon to the Pennsylvania Hospital, Philadelphia.

James H. Hutchinson, M.D., Physician to the Pennsylvania Hospital, Philadelphia.

J. H. T. King, M.D., U.S.A.

W. C. Kloman, M.D., Baltimore, Maryland.

D. S. Lamb, M.D., U.S.A.

Henry G. Landis, M.D., Niles, Ohio.

A. L. Leach, M.D., Philadelphia.

Jos. Leidy, M.D., Professor of Anatomy in the University of Pennsylvania.

Richard J. Levis, M.D., Surgeon to the Pennsylvania Hospital, Philadelphia.

J. Eneu Loughlin, M.D., Philadelphia.

W. D. Martin, M.D.

F. F. Maury, M.D., Surgeon to the Philadelphia Hospital.

G. T. MAXWELL, M.D., New Castle, Delaware.
JAMES D. MCGAUGHEY, M.D., Wallingford, Connecticut.
J. EWING MEARS, M.D., Philadelphia.
J. F. MEIGS, M.D., Physician to the Pennsylvania Hospital.
CHARLES K. MILLS, M.D., Philadelphia.
A. K. MINICH, M.D., Philadelphia.
S. WEIR MITCHELL, M.D., Member of the National Academy.
RICHARD MOFFATT, M.D., Philadelphia.
CHARLES B. NANCREDE, M.D., Philadelphia.
WILLIAM F. NORRIS, M.D., Clinical Lecturer on Diseases of the Eye and Ear, University of Pennsylvania.
G. D. O'FARRELL, M.D., Philadelphia.
ISAAC OTT, M.D., Easton, Pa.
JOHN H. PACKARD, M.D., Surgeon to the Episcopal Hospital, Philadelphia.
JOSEPH PANCOAST, M.D., Professor of Anatomy, Jefferson Medical College, Philadelphia.
W. H. PARISH, M.D., Philadelphia.
JOHN S. PARRY, M.D., Physician to the Philadelphia Hospital, Blockley.
WILLIAM PEPPER, M.D., Physician to the Philadelphia Hospital, Blockley.
EUGENE PEUGNET, M.D., New York.
ISAAC RAY, M.D., Philadelphia.
JOSEPH G. RICHARDSON, M.D., Lecturer on Morbid Anatomy, University of Pennsylvania.
J. T. ROTHROCK, M.D., Wilkesbarre, Pa.
C. SEYMOUR, M.D., Hinsdale, Mass.
ALFRED STILLÉ, M.D., Professor of Theory and Practice of Medicine, University of Pennsylvania.
J. STOCKTON-HOUGH, M.D., Philadelphia.
GEORGE STRAWBRIDGE, M.D., Clinical Lecturer on Diseases of the Eye, University of Pennsylvania.
JAMES TYSON, M.D., Clinical Lecturer on Microscopy and Urinary Chemistry, University of Pennsylvania.
E. W. WATSON, M.D., Philadelphia.
W. H. WEBB, M.D., Philadelphia.
J. WM. WHITE, M.D., Surgeon to the Eastern Penitentiary, Philadelphia.
DE FORREST WILLARD, M.D., Philadelphia.
HORACE WILLIAMS, M.D., Philadelphia.
W. H. WINSLOW, M.D., Philadelphia.
H. C. WOOD, JR., M.D., Physician to the Philadelphia Hospital, Blockley.
FRANK WOODBURY, M.D., Philadelphia.
H. E. WOODBURY, M.D., Washington, D.C.

ORIGINAL LECTURES.

CLINICAL LECTURE

ON EMPHYSEMA OF THE LIVER OCCURRING IN A CASE OF TYPHOID FEVER.

BY J. FORSYTH MEIGS, M.D.,

Attending Physician to the Pennsylvania Hospital.

(Delivered at the Pennsylvania Hospital, September 2, 1872.)

Notes by Dr. Wharton Sinkler.

G. O., æt. 25 years, was admitted to the Pennsylvania Hospital, August 30, 1872. Sailor; single; was born in Nova Scotia, and has been going to sea for ten years.

He sailed from Boston, August 23, in excellent health, and when three days out was taken with diarrhœa and severe headache. He slept well at night, however.

On admission, was extremely feeble; pulse weak and frequent; face dusky, eyes suffused and conjunctiva injected; skin very hot; tongue coated and pasty; had diarrhœa. Heart very weak. Answered with hesitation, and stammered slightly. Mind acted very slowly, and it was impossible to get an accurate history of his past life; in regard to recent events he was more clear. He stated that until March, 1872, he had enjoyed robust health; at this time he contracted syphilis. He has had a cutaneous eruption, sore throat, and periosteal pains. About one month ago, he says, he had two chancres and gonorrhœa, for which he was treated in Boston, in the Massachusetts General Hospital. The chancres soon healed, but the urethral discharge did not cease until three or four days after leaving the hospital.

The patient was at once put in bed, and ordered infus. digitalis f℥ss t. d., and for the diarrhœa, opii gr. ¼, capsici gr. j, acid. tannic. gr. ij, every two hours, whisky, f℥viij a day, milk, and beef-tea.

Temperature in the evening of this day, 102°.

August 31.—Was delirious all night, and could only be kept in bed by forcible restraint. Tongue dry and red; skin dingy; heart feeble; vomits frequently. One quart of urine was drawn off by catheter this morning. The digitalis was stopped, and spt. terebinth. gtt. x every two hours, and quiniæ sulph. gr. viij a day, ordered. Pulse, 120; resp., 24; temp., 101°. Evening temp., 101½°. The urine was found to contain a marked quantity of albumen, and a specimen was sent to Dr. Richardson, Microscopist of the Hospital, for examination. He reported that he detected "small hyaline and medium-sized granular tube-casts, the latter much broken up, the former showing well. Some few of the casts have attached to them epithelial cells, which exhibit minute oil-globules."

September 1.—Skin is not so dingy. Rose-colored spots appearing on chest. Abdomen slightly tympanitic. Tongue coated, and sordes on teeth. Had no stool yesterday until afternoon, when he had a copious watery evacuation. Passes urine himself. Stop turpentine mixture, and give acid. muriat. dil. gtt. x t. d. Pulse, 110; resp., 30; temp., 103°.

September 2.—Somewhat better to-day. Does not vomit, and bowels quiet; takes his nourishment well. Sleeps most of the time, occasionally muttering, and has subsultus tendinum.

September 3.—Looks rather more intelligent, otherwise about the same; spt. chloroform English f℥ss every three hours. Pulse, 112; resp., 24; temp., 101°. Evening, pulse, 108; resp., 24; temp., 102½°. On adding nitric acid f℥ss to urine f℥ij in a test tube, and applying heat, an intensely dark-red color is produced, showing, according to Dr. George Harley, the presence of a great amount of urohæmatin.

September 4.—About the same. Still delirious at night, but quiet during the day; easily roused, and answers when spoken to. Pulse, 114; resp., 28; temp., 101°. Evening, pulse, 112; resp., 30; temp., 102½°. To f℥iv of urine sufficient nitric acid to set free the coloring-matter was added, and then placed in a f℥vj bottle. Ether sulph. f℥ss was poured in, and the whole put aside for twenty-four hours. At the end of this time the urohæmatin dissolved in the ether had formed a layer resembling currant jelly, on the surface of the liquid.

September 5.—Had a hemorrhage from the bowels last night, and has had several bloody stools to-day. Takes milk and beef-tea readily, but refuses to swallow whisky. Prostrated, dull, and heavy. Urine contains about one-eighth albumen; sp. gr. 1020. ℞ acid. tannic. gr. v every hour. Pulse, 100; resp., 30; temp., 100°. Evening, pulse, 120; resp., 24; temp., 104°.

September 6.—No hemorrhage since yesterday. The tongue moist and cleaner. Ordered one pint of wine a day, instead of the whisky, as this sickened him. Pulse, 114; resp., 28; temp., 103°. Evening, temp., 104°.

September 7.—Had a small tarry stool this morning. Tongue pasty. Takes milk and wine freely; is heavy and somnolent. Pulse, 108; resp., 24; temp., 102°. Evening, pulse, 126; resp., 30; temp., 103°.

September 8.—Hemorrhage from the bowels has returned. Tongue dry and covered with sordes. ℞ acid. gallic. ℈j every two hours. Pulse, 114; resp., 28; temp., 103°. Evening, pulse, 108; resp., 26; temp., 103°.

September 9.—About the same; no hemorrhage since yesterday; increase wine to Ojss a day. Pulse, 114; resp., 26; temp., 101½°. Evening, pulse, 116; resp., 24; temp., 102°.

September 10.—More feeble, but takes all his nourishment. No more hemorrhage. Skin more dusky. Stop gallic acid, and take spt. chloroform English f℥j every two hours. Pulse, 100; resp., 18; temp., 102°. Evening, pulse, 144; resp., 30; temp., 102°.

September 10.—Had a profuse hemorrhage from bowels last night; is weaker. Pulse, 140; resp., 33; temp., 103°. Evening, pulse, 144; resp., 30; temp., 102°.

September 12.—No more hemorrhage; yesterday in the afternoon had a dark feculent stool. There is no abdominal tenderness. Pulse, 164; resp., 30; temp., 102°. Evening, pulse, 141; resp., 30; temp., 104°.

September 13.—Yesterday evening had a chill, sank rapidly, and died at one o'clock this morning.

Autopsy, at 12½ P.M., *eleven and a half hours after death.*—Frame large; limbs somewhat thinned, but not emaciated. Marked swelling at sides of neck—both sides—which extends downwards to sides of thorax, over deltoids, and over clavicular region, evidently subcutaneous emphysema. Much discoloration, from stasis of dependent parts of body. On opening the chest and abdomen, air escaped with a hiss from the peritoneal sac. This was found afterwards to have come from the intestine through a perforation. The lungs were pale, fully distended with air; only basis of inferior lobes congested moderately and slightly splenified; scarcely any old pleuritic adhesions; perhaps two ounces of pinkish serum in pericardium; heart natural.

Abdomen.—Liver large, especially right lobe, which was considerably thickened. No adhesions of liver to diaphragm, and, therefore, no possible communication

between liver and thorax. Spleen moderately enlarged, and dark-colored. On lifting the intestines, there was found in the left side of the abdomen a good deal of thin, dirty, feculent fluid, which had escaped through a small perforation in the ileum. No adhesions nor bright vascularity of the peritoneum, or of the intestines; no lymph-exudations. Over the lower portions of the ileum were some dark congested spots. On laying open the ileum, Peyer's glands were found to be generally ulcerated, with long flocculi hanging from the centres of the patches, colored yellow by fæcal matter. Ulcers not deep, edge of ulceration thin, but cut abruptly from the general surface. In the lower few inches of the ileum, much blackish material was strewed over the surface, evidently altered blood. Mesenteric glands enlarged, highly vascular, and softened; many of the solitary glands of the intestine were ulcerated.

Liver was much enlarged (one-third), color dirty brownish-yellow. Tissue everywhere highly crepitant, light and spongy. Adhesion greatly lessened, so that the finger could be readily thrust in, making a ragged hole. Pieces cut off and thrown into water floated exactly like lung, and as lightly. Tissue singularly cribriform, exhibiting innumerable small cavities, like the cells of the lungs. No large cavities in this organ. On pressure, much dirty, frothy, thin liquid escaped, which looked like ichor, but not like pus.

No large or small purulent collections. Gall-bladder filled with thin yellowish bile.

Kidneys were both considerably enlarged (about one-half), dark-colored and congested; distinctly crepitant, but not so much so as the liver; not floating in water. The capsule was easily detached.

Microscopic Examination of the Liver and Kidneys.—Liver very fatty, cells broken up and disintegrated, scarcely any of full size and natural character, fat in large drops scattered over the field, and the broken, small, angulated, and irregular cells all containing much fat in minute refracting points.

Kidneys not fatty. Tubes large, swollen, and crowded with dark, cloudy cells, not fatty. Innumerable loose epithelial cells in field, which are very granular and cloudy.

Remarks.—There was something about this man's appearance, when I first saw him, which struck me as peculiar. He was sitting upon a sofa outside of the ward, having just come in from his ship. He was dull, looked heavy and stupid, had a rather thinnish face for a man of his large and powerful build, spoke slowly and almost in a stammering way, and showed a sluggish memory as to facts.

The next day, when he was in bed, I suspected he had typhoid fever; and yet there was an exhaustion which you do not often see so early in the disease. His eyes were somewhat sunken in the orbits, and his face was haggard and rather pale, not dusky as you so often see in this fever, whilst his thorax was dark-colored, approaching to a cyanotic hue. Finding that his bladder was rather full, I drew off the urine with a catheter, and upon examination found that it contained a good deal of albumen. On adding an excess (about one-fifth) of nitric acid to it, and boiling, it became very dark in color, of a violet tint. This led me to suspect the presence of a large amount of coloring-matter in it, of urohæmatin, and I requested the resident physician, Dr. Cox, to add nitric acid in excess to four ounces of the urine, to shake this well together, then to put it into a six-ounce phial with one ounce of sulphuric ether, shake it again, and let the mixture stand. Thus treated you saw it the next day, when, if you recollect, there was on the surface of the fluid a layer of about three quarters of an inch in thickness, of a jelly-like substance, of a dark pink color. This is Dr. George Harley's method of showing the presence of large amounts of urohæmatin, and demonstrated the fact that the patient was throwing off through the kidneys a great excess of the coloring-matter of the blood, the result, according to Dr. Harley, of a very rapid and unusual destruction of the red corpuscles. This condition of the urine explained, I thought, in part at least, the unusual exhaustion of the patient.

After this the patient grew gradually worse, had, as you have all heard from the notes of the case, obstinate and copious hemorrhage from the intestines, and died. Whether this rapid loss of the red corpuscles of the blood had anything to do with the condition of the liver found after death, I do not know. This condition is so involved in mystery, that it is important to put upon record all that was observed in the case.

I showed you the liver, kidneys, and small intestines at the last clinic, and told you how very rare this condition of the liver—which is called by some emphysema hepatis, and by certain French writers pulmonization of the liver—is, and how fortunate you were in being able to see so curious a specimen of disease.

Emphysema of the liver must be a very rare phenomenon, since it is mentioned by so few observers. In that great treasure-house of pathological medicine, Rokitansky's Pathological Anatomy, I cannot find a single specific reference to it. I have looked through seven volumes of the Year-Books of the Sydenham Society, and did not find a case. Bamberger, in Virchow's Hand-book of Pathology and Therapeutics, in the chapter on the liver, makes no mention of it. Neither Budd in his Treatise on the Liver, nor Watson in his Practice, nor Graves, who saw so much typhus in Dublin, in his great work on the Science of Medicine, nor the writers on Typhoid Fever and Diseases of the Liver, in Reynolds's System of Medicine, nor the Compendium de Médecine Pratique, even glance at it.

But Louis, in his work on Typhoid Fever, whilst he states that he has never seen it in that fever, tells us that he has met with it three times in patients who had died of other acute diseases. And in his work on Phthisis he reports at length an instance in which it occurred at the close of the disease. Murchison, in his work on Fevers, does not seem to have seen it himself, but refers to Louis's cases, and quotes four cases which were seen in typhus fever by two French observers, Barudel and Jacquot.

Frerichs, in the second volume of his work on Diseases of the Liver, Sydenham Society edition, vol. ii. page 369, refers to it, though he does not seem to have met with it himself. He mentions, however, the case of a man who had died of ileus, in whom there was enormous tympanitic distention of the walls of the abdomen, and in whom air had been forced up the common duct of the liver into the gall-bladder, so that the latter was found after death distended with air to the size of an ostrich

egg, and without any bile in it. But this was not the kind of case we have had before us, nor the kind referred to as a true emphysema hepatis.

Louis says (Typhoid Fever, translated by H. I. Bowditch, Boston, 1836, vol. i. 263), "There was no emphysema [of the liver] in a single case; but in those patients who died at various periods from the commencement of the disease, the blood-vessels of the liver contained a greater or less quantity of air."

In the remarks on the liver in patients who died of other acute diseases (vol. i. p. 265), he says, "The color of the liver was greenish, or of a pistachio color, throughout the organ in five cases, in three of which there was emphysema of the liver. . . . This emphysema, which coincided with an analogous state of the cellular tissue of the neck, to a greater or less extent, was especially remarkable, as I have elsewhere observed in an analogous case [work on phthisis], in this, that notwithstanding the great number of void spaces in the liver, the organ was not larger than natural. In whatever light, however, we regard the origin of this affection, whether we consider it to have commenced before or after death, it seems to me impossible to conceive without astonishment of the fact that an affection heretofore called putrid fever has never given rise, in any one of the forty-six cases we are analyzing, to any phenomenon justifying this title, whilst other diseases, whose natures do not repel the idea of putridity, would seem, from the above result, to have this character so often."

In his work on Phthisis (Syd. Soc. ed., p. 123) Louis gives a case of phthisis in a man twenty-seven years of age, in whom at the autopsy there was found general emphysema, more highly developed in the neck and lateral parts of the chest than elsewhere,—accompanied with phlyctenæ filled with a violet-colored liquid. The arms crepitated, and were yet very small,—a proof of the extreme emaciation of the subject. False membranous adhesions, rarely separable, existed both on the liver and the diaphragm. The liver was of dark bistre-color, of very moderate size, very soft, and of such a specific gravity that it floated on the top of water like a healthy lung; internally, it exhibited an infinite number of empty spaces, varying in size from that of a millet-seed to that of a pea, and, taken together, forming a larger space than that occupied by solid tissue.

He says, speaking of this emphysema, that it does not appear to have been "the most remarkable phenomenon connected with it; its size, scarcely equal to that existing in the healthy state, seems to me still more extraordinary. For if we suppose that the emphysema was developed shortly after or a little before death, we must admit the liver to have previously been most extraordinarily small; and inasmuch as there has, perhaps, been no example met with of so small a liver as we should be constrained to imagine under this hypothesis, we are almost inevitably led to believe that, in the case in question, the emphysema was developed long before death, in a gradual manner, and in consequence of some morbid alteration or other of the parenchyma of the organ."

In the case, the specimens of which you saw the other day, there was certainly no emphysema of the neck before death, or, at least, none was observed, as I believe it would have been had it existed. It is difficult to suppose that the singular cribriform and spongy character of the liver which you saw, and which depended upon the formation in the tissue of the gland of innumerable small open spaces filled with gas or air, so that the liver looked like lung-tissue, or like a very delicate honey-comb, could have been all produced in the eleven hours and a half which elapsed between the moment of death and the autopsy. Moreover, there was no decomposition of the tissues in other parts of the body. The weather was not very hot, and certainly there was no putrefactive process going on in the kidneys, which, like the liver, though to a much smaller extent, were also emphysematous.

The probability seems to me very strong, that the true nature of this singular lesion is best given by Frerichs, whose words I shall quote. He says, "The cause of this peculiar development of gas [chapter on Emphysema Hepatis, Disease of the Liver, Syd. Soc. translation, vol. ii. p. 369] in the liver is obscure, and the nature of the gas is unknown. We are not, in my opinion, warranted in assuming, with Piorry, that the intestinal gas reaches the liver through the eroded roots of the portal vein. It is more probable that the affection ought to be regarded as a local process of disintegration, and that it originates, under certain circumstances, in those complicated metamorphoses of matter which occur in the liver from the presence of large quantities of the carbo-hydrogens. Whether emphysema of the liver may, as Louis and Piorry believe they have proved, exist during life, and be diagnosed from the disappearance of the hepatic dulness, can only be satisfactorily determined by further observations."

The treatment pursued in the case was of no avail, though I do not see, even now, how it could have been mended. There must have been some deep-seated fault in both the fluids and solids of the patient, which were beyond the resources of the medical art. He was kept rigidly at rest in bed, as fully nourished with milk and beef-tea as possible, and he had the best remedies within our control for the suppression of the hemorrhage and to quiet the nervous phenomena present.

Dr. Charles Cambray, of Cambrai (De la Dyssentérie et des Maladies du Foie, p. 533), speaks of having seen, on one occasion, emphysema of the liver.

Suicide attempted by Means of Petroleum (*Mitt. d. Aerztl. Ver. in Wien*, 1872, No. 6).—A woman, forty-five years old, drank one-half litre of petroleum, such as is found in the shops, for purposes of suicide. Symptoms of intoxication were very slight; pain in the stomach, and fever, were almost entirely absent. The cutaneous surface smelt strongly of the petroleum, but not the breath. Her urine contained albumen, pus, and epithelium, and manifested an alkaline reaction. The strong odor of petroleum remained upon the skin for six days, after which the woman recovered entirely. It is interesting to note that the use of petroleum as a substitute for brandy is a common matter among the lower classes in the suburbs of Vienna.

ORIGINAL COMMUNICATIONS.

THE NEW OPERATION FOR COLORING CORNEAL OPACITIES.

BY R. J. LEVIS, M.D.,

Surgeon to the Pennsylvania Hospital, and to the Wills Ophthalmic Hospital.

THE artificial coloring of corneal opacities, which, from their characteristic whiteness, are termed leucoma or albugo, is a new surgical procedure that has practical application for cosmetic objects. The same coloring process, applied as I shall suggest, with the object of rendering certain portions of the transparent cornea opaque, so that no visual rays can be transmitted, will prove of value for the palliation or correction of some optical defects of vision.

The disfigurement of the glaring white opaque spaces of the cornea can be concealed by indelibly tinting, so that if central, they shall show the blackness of the natural pupil, or if peripheral in location, the color of the underlying iris may be most deceptively imitated. Should even the entire cornea be opaque, a very natural imitation of the appearance of the whole circle of the iris and the pupil can be accomplished.

The tinting of corneal opacities is effected by imbuing them with various pigments which remain permanently in the tissues. The operation is almost painless, and, in my experience, no irritation has followed in any case. It is simply that which, when applied to the skin, is called *tattooing;* and in the eye the coloring-matter is, on similar principles, introduced beneath the epithelial surface of the cornea.

Various suggestions of instruments have been made for the performance of this little operation by Wecker, of Paris, who lately introduced it, and by other operators, such as a lancet-point. a grooved needle, and sewing-needles bound around a handle, as a pen-holder. After some experience, I find that the most convenient and effective instrument is made by binding together, with a thread, from three to six very fine sewing-needles, for use in accordance with the size of the blemish to be removed. The points of the needles may be made to project equally by holding them perpendicularly on a hard surface before the binding is tightly applied. By inserting the little bundle of needles into a handle, as that of a cataract-needle, or into a hole drilled in the end of a stick of similar form, the instrument is rendered complete.

Coloring-materials of various hues and characters may be used, such as many of the water-colors of the artist, but the great essential is a deep-black tint; and this is perfectly effected by Indian ink, which is a combination of lampblack and gelatin. It seems to be simply requisite that the pigment be unirritating and insoluble matter, and in a state of minute subdivision. For tinting in imitation of the iris, blue or brown pigments will be required, and other colors may be blended with artistic effect. The paints are prepared for use by rubbing them down to a pasty consistence with water. With the object of preventing the prepared material from drying, so that it may continue ready for use, the mixture may be made with the addition of glycerin.

To perform the operation, I do not ordinarily find it necessary with adults to use either the speculum or the fixing forceps. The upper eyelid is elevated by the operator or by an assistant, one finger retaining the lid in position whilst the adjoining finger presses against the inner canthus to steady the eyeball; and the patient is directed to look intently with both eyes at some point on the wall or the ceiling of the room. Operations on children or on restless adults may require the spring speculum and fixation of the globe with forceps, and even anæsthesia might in some cases be necessary.

The surface of the opaque spot should be wiped clear of moisture with a piece of lint or linen, and the paint is then thickly applied over it with a small pencil. The needle-points are made to penetrate repeatedly and rapidly in varying directions, until much of the opaque surface is gone over and is imbued with the pigment. As the extent and perfection of the coloration cannot be at once accurately determined, two or more repetitions of the operation are usually required.

When an accurately formed pupillary margin or a peripheral circle of the iris is to be represented, it is well to make, in a careful manner, circular dotted lines of color with the needle-points. The inclosed space can afterwards be rapidly filled in with color.

It is not necessary, as has been directed, that the patient's eye should remain open until the pigment dries, as the coloring-matter that is imbedded in the tissues cannot be washed off by the tears, and the drying of the remaining excess on the surface will not tend to fix it there.

In regard to the relief of optical defects by rendering the cornea in some portions opaque, a stenopæic effect may, for instance, in certain cases of permanent mydriasis, be produced by leaving only a central pupil-like space uncolored for the transmission of visual rays.

The same plan may be advantageous in the defect of vision of albinism, substituting the deficiency of pigment in the choroid; and it may also apply to incurable cases of photophobia, by partially excluding the light.

In cases of the existence of unnatural openings in the iris, and of coloboma, whether congenital or due to traumatic causes, the tinting process may be available to shut off the most eccentric rays, and dazzling and confusion of vision will thus be avoided.

The procedure would seem to be available for the relief of the optical defect of the extreme astigmatic refraction of conical cornea, the apex of the conicity being rendered opaque after the performance of an iridectomy downwards.

Irregular astigmatism, which is a varied refraction in the same optical meridian, and is often due to irregular curvature of the cornea, caused by thinning after severe inflammation, traumatic injuries,

and the faulty union of the section in extraction of cataract, may be palliated by obscuring the cornea in curvatures of its most defective refraction.

CLINICAL NOTES.

BY C. H. BURNETT, M.D.

THE first and second cases which I shall describe show the advantages, in some forms of deafness, of two new operations introduced to otiatrics by Prof. Adam Politzer, of Vienna.

The indications for, and the method of performing them have been fully explained by Prof. Politzer, in a lecture, translated into the *Medical Times* for March 15, 1872.

In order, however, to bring before the reader's mind the chief points in that lecture, I shall simply state that the operations, very similar in their nature to each other, are indicated in cases of chronic deafness due to retraction of the membrana tympani as a whole, or when bands of fibrous tissue in any part of the membrane interfere with its vibration.

The first condition is characterized by prominence of the folds of the membrana tympani, especially the posterior fold, and the foreshortening of the handle of the malleus.

The second condition is characterized by prominent bands or ridges running across the surface of the membrane, with or without foreshortening of the handle of the malleus. These bands hold the membrana tympani in a fixed position, and any relief afforded by the air-douche is only temporary, for the membrane soon returns to its former position in consequence of contraction of the fibrous bands.

In order to relieve this abnormal tension of the membrana tympani, Politzer has performed an operation in a series of cases of each form of the disease, consisting of cutting through the posterior fold of the membrana tympani in the former case, and of a severance of the fibrous bands in the latter. This is accomplished with a delicate knife, rounded and sharpened at the end, and which is curved at an angle of forty-five degrees from the handle, or straight, according to the choice of the operator. Politzer recommends the curved form, as allowing more freedom in vision, the hand of the operator being below and not between the ear of the patient and the eye of the surgeon, as it is very apt to be if one uses the straight form of knife.

Gruber prefers a perfectly straight knife in all operations on the ear.

In performing the following operations, I have adhered to Politzer's advice respecting the form of the instrument.

The first case was one of so-called chronic catarrh of the middle ear, in a man sixty-three years old, who presented himself at the Ear Department of the Philadelphia Dispensary last April, complaining of deafness, and desiring treatment. The right ear was the worse, the watch audible 10 metres to the normal ear being heard only 7 cm. The membrana tympani on that side was retracted, marked with cicatrices, the *folds* were *prominent*, and the handle of the malleus was greatly foreshortened. The air-douche gave no relief, being unable to overcome the retraction of the membrana tympani. I then determined to cut through the posterior fold of the membrane, taking care to cut from above downwards, in order to avoid severing the chorda tympani, which lies adjacent to the point usually chosen for the operation in question.

The operation required but a few moments, caused very little pain, and but a drop of blood exuded from the wound, which was 2 mm. in length. There were no unpleasant symptoms of nausea or dizziness on the part of the patient, who never flinched, but remained sitting upright in an ordinary chair, without any support to his head; although it is advisable in most cases to have the head of the patient placed against a firm support, to prevent any sudden movement away from the operator.

The hearing increased instantly to 17 cm. for the watch. Two days later, the hearing-distance had increased to 50 cm. for the watch, showing that, although this patient was old and not the best subject for such an operation, enough was gained by the operation to demonstrate its practicability.

The second operation was upon a female thirty-nine years old, who had noticed deafness five years previous to the time she presented herself for treatment, in April last, at the Philadelphia Dispensary. She showed the usual symptoms of chronic catarrh of the throat and ear, the latter of the non-secretory form, and had probably been hard of hearing longer than she imagined. The right ear was the more affected, and to that the treatment was directed. The hearing-distance for the large watch, audible 10 metres to the normal ear, was reduced to 35 cm., and for the voice in conversation 3 metres. This increased to 40 cm. for the watch, and for the voice to 4 metres, after the introduction of air into the middle ear according to Politzer's method. The membrana tympani appeared very opaque and white, and a large oval cicatrix ran parallel to the handle of the malleus, posteriorly. There were a few small cicatrices in front of the handle of the malleus. The most important change, however, in the membrane, was the prominent white band of fibrous tissue running from the short process of the malleus, downwards and backwards, above the cicatrix, to the periphery of the membrane.

The treatment first pursued consisted of the application of a borax solution (℥j to Oj) to the nostrils by direct syringing. In the course of ten days the hearing-distance increased to 55 cm., beyond which point the means in use failed to advance it.

On the 3d of May I cut through the aforesaid band of fibrous tissue. The wound bled more than in the previous case, the hemorrhage amounting to several drops. There was no immediate increase in the hearing-distance, and the patient experienced some pain during the ensuing evening. This was followed by slight local redness at the point of incision, which disappeared entirely in two or three days. In eighteen days from date of operation the hearing-distance had increased to 70 cm. for the watch, and for the voice eight paces. In thirty

days the hearing-distance had reached one metre for the watch, and for spoken words ten paces.

This case I have still under observation, and although the woman is in a humble condition of life and is lactating, she is greatly improved.

The following case demonstrates the advantage to be derived from *paracentesis membranæ tympani* in the suppurative stage of otitis media acuta. Gruber has within the last two years drawn the attention of the profession to the benefit of this operation, and has delivered several clinical lectures on the subject, the most important of which have been published in the *Medical and Surgical Reporter* for June 8, 1872, and in the *Pester Mediz.-chirurg. Presse*, 8 Jahrgang, 1872, where the indications for, and the method of performing the operation are fully explained. Great caution must be exercised in making the diagnosis of a collection of exudation behind the membrana tympani, and the point of incision, when we have concluded to perform the operation, should be in the postero-inferior quadrant of the membrane.

The great advantages in this operation are that *we choose* the point of exit for the collection of exudation which lies behind the membrane, and prevent the spontaneous formation of a large perforation, with its attendant disposition towards a chronic stage.

In the following case the good results of the operation are seen.

It was performed upon a healthy mechanic, thirty-nine years old, on the 17th of last May. He had been exposed during the warm period in May to the direct rays of the sun, had been greatly heated, and had allowed himself to cool rapidly. On the 14th of May he felt great pain and deafness in left ear. The hearing-distance was reduced to 1¼ metres for the large watch already mentioned in the previous cases. The membrane was greatly infiltrated, and the malleus had become invisible. The Eustachian tubes were pervious on each side. I ordered the application of two leeches on the tragus, and rest.

Three days later, I saw the man again. The pain had increased; the membrana tympani was forced outwards, especially at the postero-superior quadrant, by a collection of exudation.

Paracentesis was therefore performed at the postero-inferior quadrant, and the pain was instantly relieved. Upon exercising the Valsalvan method of inflating the tympanum, a large drop of pus the size of a pea was forced through the opening in the membrane, and the hearing-distance increased to nearly its normal standard.

By the next day the wound had closed, the pain had not returned, and the hearing was normal.

In this case, by performing paracentesis of the membrana tympani at the right time, the patient escaped a continuance of pain, and the spontaneous opening of the membrane at a less favorable point than the one chosen for the operation.

The postero-inferior quadrant of the membrane is selected as the point for paracentesis, because the simple act of blowing the nose, on the part of the patient, forces the exudation backwards, and gravity tends to carry it downwards; the two forces insuring a complete emptying of the fluid contents of the cavity of the tympanum, if an opening in the membrane exist at the postero-inferior segment.

NOTES OF HOSPITAL PRACTICE.

JEFFERSON MEDICAL COLLEGE.

SURGICAL CLINIC OF PROF. JOSEPH PANCOAST.

Reported by FRANK WOODBURY.

EPITHELIOMA OF THE HAND.

A HALE old gentleman of 71 years exhibited a growth in the skin of his left hand over the extensor tendons of the ring and middle fingers. It had first attracted his particular attention about six months before, when it was the size of a small pea, and rather dark-colored. He thought at the time that it was a wart, but it steadily increased in size, and became the seat of a slight, burning, stinging pain. The application of nitrate of silver was made, without checking the disease, which at the date of his appearance at the clinic (Jan. 13) had attained the size of a silver half-dollar. The tumor was movable, tender on pressure; its surface was hard, rough, dry, and dark-colored, and projected from the surrounding skin, encircled by a border of inflammation. There was no hereditary tendency to cancer, and he knew of no attributable cause for the disease.

This affection is non-malignant. Its action, at first, was confined to the sub-epithelial surface of the skin, but it has now involved the entire structure of that tissue. From the mobility of the tumor we see that it has not extended below the skin so as to involve the sheaths of the tendons. It is a disease of advanced life, showing itself most frequently in the integuments of the face and back of the hand, and rarely exhibiting itself before the fortieth or fiftieth year. It is sufficiently common in both sexes.

There are two ways of treating this affection: by the use of caustics (the best of which in such cases is the chloride of zinc), and by excision. Where the epithelial growth is yet small, or occurs in numerous points, as it often does, it is best to rub or even scratch away the dark crust, and apply to the surface a half-saturated solution of the chloride of zinc, afterwards lightly covering the part with an ointment of oxide of zinc and calomel. If hairy parts are involved, as the eyebrows or temples, it will be necessary, as in sycosis, to pull the hairs before the zinc wash is applied. But when the patch is single, and is disposed to spread into the skin rather than rise into a scab, excision of the spot, including the whole substance of the skin, is the best. I usually draw the edges of the wound together with a fine silk suture; but on the sides of the nose, especially at the upper part where they are apt to come, this cannot be done. I then content myself with letting the wound heal up under cold-water dressing or a solution of sulphate of zinc, gr. j to the ounce of water.

To this case of cancer of the hand the caustic, from the comparatively large size of the cancerous spot, is not well suited. Not being able to limit its action, it might strike too deep and involve the thecæ of the tendons, which, as the skin moves over them, you see, are now free, and thus render the fingers after the cure permanently lame, by preventing the tendons from sliding in their sheaths.

The operation was then performed by including the mass between two elliptical incisions, carried at once through the skin. The isolated skin and tumor was

then seized at one end with a strong pair of forceps and torn away without the need of any dissection, exposing the outer surface of the white, glistening sheaths of the extensor tendons at the bottom of the wound. The edges of the wound were then partly brought together, without making much tension of the skin, with two or three sutures, and the part dressed with ung. zinci oxidi, and covered with cloths wet with cold water. The hand and forearm were directed to be placed in a splint and elevated in a sling, keeping the fingers extended.

Jan. 17.—Very little inflammation resulted from the operation; some œdematous puffiness existed around the wound, which Dr. Pancoast relieved by puncturing with a small bistoury. A light poultice of boiled starch, inclosed in a linen bag, was directed to be laid on the wound. When the wound began to cicatrize, it was dressed with the following ointment:

℞ Cerat. plumbi subacetat., ℥ss;
Ung. hydrarg. oxidi rubri, ʒj;
Vini opii, ℥iss.

A few days subsequently, the wound healed, and the patient returned home relieved.

RECURRING CANCER FOLLOWING OPERATION FOR EPITHELIOMA.

In this patient, a man 40 years of age, an epithelioma of the lower lip had been removed by a triangular incision some six months before. The wound had entirely healed after the operation. A malignant growth soon began to show itself as an ulcer on the surface of the lip and on either side of the cicatrix, involving all the proper structure of the lip down to the bone. An enlarged lymphatic gland could be felt under the jaw, which had begun to take on cancerous degeneration, the cancer-cells having probably been carried there by the absorbent vessels from the seat of the disease.

Ether was administered, and the patient placed in a sitting posture to prevent the blood from running into his mouth. The surgeon then carefully removed every particle of the diseased structure, and scraped the bone, at the same time removing the enlarged gland, which he cautioned the class never to fail to do early, when it first makes its appearance, whether during the progress of the disease, or following an operation for removal of cancer of the lower lip. He invariably directs the patient, after one of these operations, in case he should find, under the lower jaw, a round tumor, like a marble, that cannot be dissipated by frictions with soap liniment, to go at once to a good surgeon and have it taken out. The way of removing it is very simple; sink a tenaculum into the gland, through the skin, cut down to the gland, turn it out from the wound by pushing down the handle of the tenaculum, and pick away the gland. If the operation is delayed until the gland becomes adherent to the periosteum, it will be found too late to prevent the extension of the malignant action to the bone.

The edges of the wound were approximated by the hare-lip suture. A good result was obtained from the operation, and the wound healed shortly afterwards. The patient was warned of the liability of the disease to return, and told to apply for assistance on the first evidences of its reappearance.

A CASE OF VARICOCELE, OR RATHER CIRSOCELE.

A young man of nineteen years appeared at the clinic, January 10, with a varicocele on the left side. There was a history of onanism connected with the case, and he was pale and anæmic, with some consequent cardiac disturbance. He complained of constant dragging pain in the testicle, which he alleviated to some extent by the use of a suspensory; also of pains in the small of his back, neuralgia shooting down the outer part of his thigh, of feeling gloomy and depressed, and general unfitness for active exertion. The veins of the left spermatic cord were large and convoluted, forming a large tumor at the back part of the pendulous scrotum. The testicle was shrunken in size. This is a common result in such cases. The enlarged and convoluted valveless veins of the cord obstruct the return of blood, and thus, by producing a remora, indirectly diminish the arterial supply of the organ. This view seems to be sustained by the fact that, when the veins are properly obliterated by an operation, the testicle becomes better nourished, and soon regains its proper size. Varicocele is usually found only on the left side. This has been explained by the fact that the left spermatic vein empties at nearly a right angle into the left renal vein, while the right opens by an acute angle into the vena cava. The left also passes behind part of the sigmoid flexure of the colon, where fecal accumulation is common, and it is thought that, at times, this might interrupt the current.

This disease, like varicose veins of the legs, is often hereditary. I have several times seen varicocele existing on the right side, but never unless it was accompanied by a similar affection on the left.

The tumor formed by this affection may be distinguished from inguinal hernia by placing the patient on his back, and elevating and pressing the tumor, when it will slowly disappear. Now, if the finger be placed over the abdominal ring and the patient allowed to resume the erect posture, the swelling will return, which would be impossible in hernia. The physical characters also are dissimilar; the varicocele feels like a convoluted mass of worms, movable over each other, while a hernial tumor is more consistent and rounded.

To this enlargement of the veins of the cord (corpus pampiniforme) the term cirsocele is most appropriately applied. The term varicocele should be restricted to cases in which, in addition to the cirsocele, there is a varicose enlargement of the superficial veins of the scrotum, often connecting by intermediate veins the two corpora pampiniformia together. This is an important practical distinction, for, in the latter case, a modification of the operation is necessary to a cure.

In mild cases, accompanied by little inconvenience, there is not much required in the way of treatment; a suspensory bandage may be worn to support the part, and local applications of cold water made night and morning, and if the health is feeble, a course of tonics, with the shower-bath. In severe cases, relief can only be obtained by an operation, and this, if properly done, is unattended with much risk. It is not worth while to pass here in review the various operative procedures that have been devised for the cure of this disease. This much, however, I will say, that you must not do any cutting operation to expose the veins in order to ligate them: such a course would not unlikely be followed by fatal phlebitis.

The true indication in the operation is to strangulate the veins by a subcutaneous ligature, which shall be all the time under the control of the surgeon, without interfering with the integrity of the vas deferens. By introducing the button-operation, which I did more than twenty years ago, I have reduced the process to such a degree of simplicity that it may be considered almost perfect. The implements required are few: a very strong waxed ligature of saddler's sewing-silk or brown thread, a flat needle, rather dull at the point and not cutting at the edge, or a common darning-needle (either of which may be passed between the veins without cutting them and producing ecchymosis), and a metal disk, an inch and a half in diameter, pierced with two holes an eighth of an inch apart, with a little saddle-back soldered on between the holes, so that the edges of the orifice will not cut the ligature as it is tied, and thus impair the success of the operation. The veins should be full of blood at the time of the operation, and

the hair covering the part clipped away or shaved off. The first and most important step in the operation is to isolate the vas deferens with its attendant artery and veins from the other constituents of the cord, and hold it back with the thumb and forefinger of the left hand. This is generally easily done. But sometimes it is not. Instead of lying in its usual place at the back of the cord, and being readily distinguishable by its wiry feel, it may be found in the centre of the mass of veins, or lying on the front or sides of the cord. Sometimes there is met a vein which has undergone spontaneous obliteration, which resembles somewhat, to the touch, the vas deferens itself. Until the vas deferens can be *satisfactorily isolated*, the operation should not be proceeded with, as the inclusion of the vas deferens with the veins in the ligature would result in the suppuration and destruction of the testicle. A certain sensation approaching sickness, caused by pressure on the duct, will sometimes enable us to distinguish it from an obliterated vein, especially in cases where from the wasting of the testicle the duct itself is small and atrophied.

The second stage of the process is to pass the needle, armed with the thread, behind the mass of veins, and between them and the vas deferens. I consider this so important a step, that I do it before I put the patient under an anæsthetic. I make him sit well over the edge of a bed, or stand up; then, holding the vas deferens well back, I gradually work the needle through in front of it, piercing the skin on both sides, but sliding the needle up under the skin at the place of exit, so as to bring the two orifices of exit and entrance as near together as I can. I let the needle stand transfixed in the wound, and again examine to see that the vas deferens is safe behind the needle.

Third stage. I then lay the patient down, put him into a state of slight insensibility with chloroform or ether, and push the needle through, bringing the ligature with it. Then I enter the needle again at the place of exit, push it under the skin, and in front of the cord, to the place of entrance; draw the loop of thread eight or ten inches farther through the wound, so as to get a strong part of the ligature that could not be cut by the second passage of the needle. I then pass the two ends of the ligature through the holes in the plate, and tie them down in a bow-knot as firmly as possible. A subcutaneous ligature is now tightly tied round the whole corpus pampiniforme,—there is no fear of including too many veins. There will always be veins and arteries enough attached to the vas deferens to maintain the circulation in the testicle. In truth, we often find that the tying of the ligature excites a contraction in the walls of the veins below it, and they empty themselves of their blood probably by the deferential veins. Included in the ligature we of course have the nerves of the cord. The strangulation of these is apt to lead to dysuria. To obviate this I give the following mixture:

℞ Mist. neutralis,
Aquæ camphoræ,
Sp. mindereri, aa ℥ij;
Morph. acetat.,
Ant. tartarizat., aa gr. j;
Sp. ether. nitrosi, ℥j;
Sacch. alb., ℥j. M.

Sig.—A tablespoonful every hour till sleep and perspiration are produced.

Every third day I untie the bow-knot and re-tighten the ligature, giving the patient a whiff of chloroform to save him pain. On the third tying no pain will be felt. At the end of twelve days, the ligature may be untied or cut on the plate and taken away. The veins will be obliterated; sometimes the ligature will come away in a loop from ulcerative absorption.

The obliteration of the veins takes place first by some coagulation of blood in them, followed by a deposit of lymph in their cavities, which causes them to form a lump below the ligature the size of a walnut ordinarily, which ultimately disappears by absorption, leaving the previously enlarged veins converted into fibrous cords. In two cases only out of the great numbers upon which I have operated have I seen a lump form on the cardiac side of the ligature, and both of those cases were attended with a little local peritonitis. They did well, however, in the end.

In true varicocele, when there are large superficial veins establishing a communication between the venous systems of the two testicles, it is necessary to tie each large vein by passing a ligature under it with a delicate needle. Unless this be done, if the veins are large, the circulation may return in the ligated vessels.

The operation was performed in the case before the class in the manner above described. It proved one of the exceptional cases in which there was an obliterated vein simulating the vas deferens, and in addition the true vas was found in front of the mass of veins, instead of behind, as is generally the case.

Jan. 13.—The patient was again brought before the class, in order to have the ligature tightened.

Jan. 17.—The same process was repeated in presence of the class. On the 24th, the ligature was removed. The patient returned home a few days after, completely cured. He was directed to cover the orifice, which had been under the plate, with lint spread with compound Elemi ointment until it ceases to discharge; the other orifice made by the needle having healed by first intention. He was also advised to wear a bag-truss until the tumor made by the obliterated veins and diffused lymph around them was reduced by absorption.

Effects of Pneumothorax and of the Consecutive Effusions in the Phthisical (Dr. A. Czernicki, *Gazette Hebdomadaire*, July 19, 1872).—In the recent discussion on thoracentesis at the Académie de Médecine, M. Pidoux quoted the opinion of Laennec, that in cases of irregular phthisis, so long as there was effusion, the diathesis remained stationary, but resumed its development when this disappeared. M. Hérard defended this view, asserting that in some cases the pressure due to the effusion might hinder the development of tubercle. M. Czernicki cited two instances which he thought gave a complete confirmation to this opinion. Two tuberculous patients, in the third stage of the disease, and *in extremis*, were attacked with pneumothorax, followed by effusion. This incident, generally so justly dreaded, manifestly delayed the diathesis, and life was prolonged in both these cases to a period beyond what could have been hoped for.

These two cases were detailed with much care. M. Czernicki thought that the effused liquid compressed the walls of the cavities, producing a local anæmia unfavorable to pulmonary suppuration and to bronchitic hypersecretion. The purulent expectoration diminished; the fever, sweatings, diarrhœa, and dyspepsia disappeared, because of the healing of the pulmonary lesion, which was demonstrated by post-mortem inquiry. M. Czernicki therefore advocated, at least in certain cases, the abandonment of thoracentesis in the effusion consequent upon pneumothorax in tuberculous patients.

Subcutaneous Injections of Corrosive Sublimate in Syphilis (*Dorpat. Med. Zeitschr.*, ii. 3, 193).—E. Harsen recommends, in syphilis, the subcutaneous injection of a solution containing in each injection $\frac{1}{3}$ gr. corrosive sublimate and $\frac{1}{10}$ gr. sulphate of morphia. The advantages of this combination are: first, little or no pain in its use; secondly, no induration at the point of injection.

PHILADELPHIA
MEDICAL TIMES.
A WEEKLY JOURNAL OF
MEDICAL AND SURGICAL SCIENCE.

PUBLISHED EVERY SATURDAY BY
J. B. LIPPINCOTT & CO.,
715 and 717 Market St., Philadelphia, and 25 Bond St., New York.

SATURDAY, OCTOBER 5, 1872.

EDITORIAL.

WITH the present number the *Philadelphia Medical Times* enters upon the third year of its existence. We feel assured that the change from a bi-weekly to a weekly issue will be found to be to the advantage of our readers, and we trust it will be so looked upon by them. With the improvements which experience has shown to be desirable, our aim will be, as heretofore, to offer, in every number, valuable original matter, and a choice selection of current medical literature; to take a high stand upon all ethical points, to aid in the correction of abuses wherever they may exist within our province, and to note all matters of professional interest. We shall be wholly clear of attachment to cliques, schools, or factions, recognizing only the highest interests of the profession and the public, and putting aside all personal or private considerations. Our columns will always be open to those who wish to express their views on any subject coming within our legitimate sphere.

We trust that our labors may meet the approval and encouragement of the profession, and are the more confident, since we have received liberal promises of aid in the way of contributions from able pens for the coming winter.

PROPERTY IN PRESCRIPTIONS.

A QUESTION has recently been raised afresh as to who has the right to a physician's prescription. Does it belong to the writer, to the patient who pays for it, or to the druggist who puts it on file after dispensing the medicine in accordance with it?

It seems to us that the matter is easily settled by common sense. A physician, having examined a patient, writes directions for the putting up of the remedies he considers suitable under the circumstances; the apothecary follows his instructions, without responsibility except to conform to them; the patient takes the label as his guide, and does as he has been advised. Supposing all this to be done, the physician evidently has no more authority over that prescription, since it is the apothecary's voucher for his preparation of the medicine, and, in case of anything going wrong, would be his only safeguard; the latter has none, for it was merely an instruction to him to compound certain drugs; the patient can have none, for the circumstances under which it was given, and which he is not supposed to appreciate, may have wholly changed before six hours have elapsed from the writing of it.

The practice in London, and perhaps all over England, and on the Continent for aught we know, is for the druggist to make and retain a copy of the prescription, returning the original to the patient.

We are well aware that it is the custom here for patients to send back their phials for renewal, and for druggists to refill them, without the sanction of the physician whose name is appended to prescription No. 12345, or whatever it may be, being obtained. But this is done at their own risk; and should salivation, narcotic or irritant poisoning, or any other untoward result, ensue upon the taking of medicine so renewed, the physician's skirts would be clear. It is also the custom, and a very bad one, for patients to say to their friends, "Dr. So-and-so gave me a prescription which I am sure would do you good; I will give you the number of it:" we have known half a dozen persons to obtain medicine in this way, without any certainty that their cases were analogous to the one for which the remedies were ordered.

Sometimes, to save trouble, physicians who have occasion to make frequent prescriptions of the same compounds will give numbered formulæ to certain druggists, and order them by numbers or by special designations. But this does not change the principle. If a surgeon examines a case of disease of the eye, and writes a prescription for "collyrium adstringens," or for "tonic No. 3," any apothecary who has the corresponding formulæ can follow that direction, as if the ordinary terms were used. It is merely an instruction to him to furnish certain remedies adapted to the existing state of the patient.

This is the great principle for which we contend: that a prescription given in any case is not a thing sold and made over either to patient or to druggist, but a direction supposed to be based on that understanding of the morbid conditions which the physician alone has; and since these conditions may or may not exist at a later stage or in another case, it is at the druggist's risk that he recommends, or at the patient's risk that he orders, the filling of any prescription without direct medical sanction.

THE RECENT INTERNATIONAL CRICKET-MATCH.

ARE we a physically degenerate race? It seems to be thought by many that such an inference may fairly be drawn from the fact that our oarsmen and cricketers have hitherto been over-matched by those of the mother country. And no doubt, to a certain extent, it is so; but there are circumstances to be taken into the account, which very much lessen the apparent gravity of the situation for us.

Aside from the influences of climate and of habits of living (we allude now to diet, social customs, etc.), there is the important fact that the Englishmen who have been pitted against our men were differently placed, in that they could give their whole energies of mind and body to excelling in cricket or in rowing. Voltaire's trees, he said, grew well because they had nothing else to do. Our young men make the cricket-bat or the oar a secondary matter; they reserve their powers for pursuits of graver moment.

Then, again,—and this seems a less favorable consideration,—our national temperament is more excitable and mercurial, more nervous and anxious, than the English. Business and pleasure are alike, in this country, pursued with a feverish haste. It is to be hoped that with increasing years this tendency may subside, and that as public affairs become more and more settled, men may acquire a cooler and steadier tone and habit of mind.

During the war of the rebellion, those who had occasion to see our armies could not but remark the wonderful effect of an out-of-door life, with continual exercise, upon our officers. They gained a physical development, and a cool and manly mental tone, to which many of them had previously been utter strangers. This lesson should not be lost. We are only degenerate so far as we allow excitement and luxury to obtain sway over us.

INTRODUCTORY LECTURES.

WE are informed that the introductory lecture to the coming session of the Medical Department of the University of Pennsylvania will be delivered by Prof. Carson, on Monday, October 7, at 12 M., and will be a eulogy on the late Prof. Samuel Jackson.

On the same day, at 8 P.M., the introductory to the winter session of the Jefferson Medical College will be delivered by Prof. J. M. Da Costa, who will take occasion to pay a tribute to the memory of his predecessor, the lamented Dr. Samuel Henry Dickson.

LECTURE BY DR. BROWN-SEQUARD.

THIS well-known physiologist will deliver a lecture on "The Origin and Signification of the Symptoms of Brain Disease," in the amphitheatre of the University of Pennsylvania, on Thursday evening, Oct. 10, at 8 o'clock. The profession are invited to attend.

CORRESPONDENCE.

MR. EDITOR—DEAR SIR,—I desire to call the attention of those readers of your journal who have not seen my brochure on sun-stroke to the fact that the notice of it in your last issue is largely made up of a series of careless misconceptions. I do not propose to show this in detail: *le jeu ne vaut pas la chandelle*. I will merely cite two instances, which follow one another almost consecutively in the beginning. Your reviewer says that I "dismiss the idea that the 'cardiac cases' die from coagulation of the myosine of the diaphragm, by one experiment;" whereas my real chief reason, as distinctly stated, is *clinical, i.e.*, because every observer who has seen such cases says that the *men die of syncope* through *sudden arrest of the heart's action*, not through the respiration.

Again, my critic says, "Here the grave question arises, Can we abstract heat from the deeper tissues so immediately as to immediately cure?—though, by the way, THREE *out of the* FOUR *animals so cured died shortly afterwards*." In truth, but a SINGLE *experiment* was made as to this point; and in that the animal did not die at all. (See page 74.)

The only point of force in the notice, I think, is in regard to this local abstraction of heat by external application. It did not occur to me that any would doubt it, or I would have determined the point experimentally. I find, however, in my note-book, an unpublished experiment which has direct bearing on the matter, proving that at least in these small animals it can be done. I heated the body of a pigeon locally, and abstracted heat locally from its head. At the moment of death, the centre of the brain was at 88° F., the rectum at 113° F. Yours, etc.,

H. C. WOOD.

1706 CHESTNUT ST., PHILA., Sept. 26, 1872.

SMALLPOX IN CHILI.—A letter received in San Francisco, September 24, from the United States Consul at Callao, states that the smallpox prevails in an epidemic form at many of the seaport towns on the coast between Valparaiso and Panama. The character of the disease, the writer says, is more pernicious than the ordinary smallpox, and much more destructive to life.

The letter continues: "In one hospital at Santiago, Chili, out of fifty-eight patients entered in one week, fifty-six died; and, as there are eight or ten such hospitals in that city, you can conceive its destructiveness.

"The disease is making its way steadily to Callao."

PROCEEDINGS OF SOCIETIES.

INTERNATIONAL OPHTHALMOLOGICAL CONGRESS.

THE following is an abstract of the scientific work of this body at its recent session:

At 11 A.M., Thursday, August 1, the Congress assembled in the library of the College of Physicians, Trafalgar Square. The walls were hung with the portraits of the old English celebrities in medicine. Harvey's picture hung behind the President, and above were his dissections of the blood-vessels of the human body.

Mr. Critchett welcomed, in French, the members of the Congress. He named the officers of the meeting, viz.: President, Prof. Donders; Vice-Presidents, Prof. Williams, of Boston, and Prof. Warlomont, of Brussels; Secretaries, Mr. J. Soelberg Wells and Prof. Zehender.

The Congress then listened to the following papers and communications:

THURSDAY.

Dr. B. Joy Jeffries (Boston), "On the Use of Ether in Ophthalmic Surgery."

Dr. De Wecker (Paris), "On the Surgical Treatment of Optic Neuritis by Opening the Optic Nerve-sheath."

Dr. Warlomont (Brussels), "Sympathetic Ophthalmia."

Dr. Bader (London) exhibited a case of pannus treated by sulphate of quinine; also a case of conical cornea treated by Graefe's method.

Mr. Critchett (London) exhibited another patient with conical cornea, also operated on by Graefe's method.

Dr. Taylor (Nottingham), on "Extraction of Cataract."

Dr. Rosier, on "Proposed Alterations in the Operation of Linear Extraction of Cataract."

Dr. Warlomont (Brussels), on "Proposed Changes in Cataract Operations by Extraction through the Cornea."

Dr. Hansa (Copenhagen), on "Forty Cases of Extraction of Cataract by Liebreich's Method."

Dr. Dudgeon, "On the Mechanism of Visual Adjustment." [This paper was objected to by the President, as containing nothing new from what he (Prof. Donders) had already published.]

Dr. Woinow (Warsaw), on "Accommodation and Refraction in the Eyes of Children."

Dr. Carreras (Spain), on "Cysticercus within the Globe."

Dr. Galezowski (Paris), on a "Case of Aneurism of the Central Artery of the Optic Papilla."

FRIDAY, AUG. 2.

Dr. Vose Solomon, on "Section of the Ciliary Muscle for Myopia."

Dr. Carter (London), on a "New Form of Demonstrating Ophthalmoscope, and a New Form of Perimeter."

Dr. Hogg (London) showed another form of divided lens to use in the same method of ophthalmoscopy.

Dr. Brettaner (Trieste) exhibited a series of fields of vision drawn from Förster's perimeter.

Dr. Wolfe (Glasgow) reported eighty-two cases of traumatic cataract on which he had operated.

Dr. Pagenstecher (Wiesbaden) exhibited drawings for an "Atlas of Pathological Histology of the Eye."

Mr. Taylor (Nottingham) showed a patient operated on by him for cataract by the method proposed in his paper previously read.

Dr. Zehender (Rostock) described a case of congenital malformation of the eyes in a child. The specimen and drawings were exhibited.

Dr. Robertson (Edinburgh) described a case of Irideremia.

Dr. Doijer (Leyden) related the case of a medical student with total absence of the iris from its position.

Dr. Galezowski (Paris) spoke of four cases of the same peculiarity.

Dr. Williams (Cincinnati), papers on "Ulcus Corneæ Serpens treated with Carbolic Acid," and on the "Treatment of Chronic Iritis by Warm Poultices."

Mr. Cooper (London), on "The Ophthalmoscope as an Optometer in Astigmatism."

Dr. Javal (Paris) showed how the same ideas had been carried out on the other side of the Channel.

Dr. Jeffries (Boston), on "Test Types and Visual Acuity."

Dr. Oldham, on "An Improved Form of Ophthalmoscope."

Dr. Schröter, on a "New Form of Binocular Ophthalmoscope after Dr. Coccius'."

Dr. Samelson (Manchester), on "Diphtheritic Conjunctivitis."

Dr. Lobo (Rio de Janeiro), on "Distances between the Anterior and Posterior Surfaces of the Crystalline Lens and Cornea."

Dr. Noyes (New York), on "Muscular Asthenopia and its Complications."

Dr. Williams (Boston) here, in behalf of the American Ophthalmological Society, invited the International Congress to visit the United States at its next meeting in 1876, the Centennial Anniversary of American Independence. This invitation was finally accepted.

Thursday evening, a conversazione took place at Mr. Bowman's. Optical and ophthalmic instruments were exhibited, also very many ophthalmoscopic pictures.

Friday evening, a soirée took place at Mr. Critchett's house.

SATURDAY, AUG. 3.

Mr. S. Watson (London) exhibited his plan of applying cold to the eye by water in small rubber bags; he also read a paper on Dermoid Cysts.

Mr. Teale (Leeds), on his operation for Symblepharon; two patients shown.

Dr. Wolfe (Glasgow) explained his own method for this operation.

Dr. Javal (Paris) presented the report of the committee of the Congress, recommending metrical and decimal series in trial-glasses.

Dr. Schmidt, paper on the "Distention of the Optic Nerve-sheath in Optic Neuritis."

Dr. Green (St. Louis) read a paper on test types modified from Snellen's.

Mr. Power (London), paper on "Transplantation of the Cornea."

Dr. Williams (Boston) showed his needles for stitching the cornea in cataract operations.

Mr. Bowman (London) spoke of the following operations: 1st, for precising and placing an artificial pupil; 2d, for removal of dense papillary membranes; 3d, for double iridectomy on the same eye by two knives at the same time; 4th, for conical cornea, by trephining the cornea and other methods.

Dr. Quaglino (Naples) spoke on "Sclerotomy in Glaucoma."

Dr. ——, on "Cutting the Sclerotic for Glaucoma."

Dr. Noyes (New York) exhibited eye-specula, and showed his form of register to be used in writing out cases.

Dr. De Wecker (Paris) then proposed that, the hour of three o'clock having arrived, the Congress listen to Prof. Donders, which the members did with the greatest attention. He spoke of and exhibited an instrument for measuring the distance between the lens and cornea. He then criticised and exploded Förster's idea that accommodation will take place when the lens is absent (great applause). He also spoke on traumatic keratitis, and in reference to the pus-cells and the corneal corpuscles.

The *Compte-Rendu* will appear in English, and will contain some other papers besides those alluded to.

REVIEWS AND BOOK NOTICES.

FUNCTIONAL DISEASES OF THE RENAL, URINARY, AND REPRODUCTIVE ORGANS, WITH A GENERAL REVIEW OF URINARY PATHOLOGY. By D. CAMPBELL BLACK, M.D., L.R.C.S. Edin., Member of the General Council of the University of Glasgow, etc. etc. Philadelphia, Lindsay & Blakiston, 1872. Pp. 300.

This volume—the expansion, as its author tells us, of a proposed article for the *British Medical Journal*—is evidently written by a gentleman of considerable practical experience, deep thought, and extensive reading.

The work begins with a disquisition upon the conditions affecting the secretion of urine, with special reference to suppression, in which those all-important bases of exact medical science, the pathology and morbid anatomy of disease, are by no means neglected. Following this part, about seventy pages are devoted to a review of the varieties, causes, and management of retention of the urine after its secretion; and the remainder of the book is chiefly occupied with excellent investigations into the pathology and treatment of nocturnal enuresis, spermatic incontinence, and the allied subjects of masculine impotence and sterility, all of which, the author most judiciously maintains, have been quite long enough abandoned by the regular profession to designing charlatans, who not only take advantage of the natural anxieties which assail sufferers from sexual disorders, but systematically aggravate the apprehensions of their victims, from base pecuniary motives. The style of the author is clear, easy, and agreeable, although a few careless infelicities of expression mar its general perspicuity. On page 150 we note that the author exhibits a misapprehension of the mode by which white blood-corpuscles wander out through the vascular walls. Nevertheless, on the whole, his work is a valuable contribution to medical science, and, being penned in that disposition of unprejudiced philosophical inquiry which should always guide a true physician, admirably embodies the spirit of its opening quotation from Prof. Huxley: "We live in a world which is full of misery and ignorance; and it is the plain duty of each and all of us to try to make the little corner he can influence, somewhat less miserable, and somewhat less ignorant, than it was before he entered it."

GENERAL AND DIFFERENTIAL DIAGNOSIS OF OVARIAN TUMORS, WITH SPECIAL REFERENCE TO THE OPERATION OF OVARIOTOMY, ETC. By WASHINGTON L. ATLEE, M.D. Philadelphia, J. B. Lippincott & Co.

How the times change, and we with them! A few years ago, ovariotomy was under the ban both here and abroad. We well remember those dog-days of incandescent controversy and fierce bickerings,—days in which the ovariotomist was almost tabooed from polite society, and hardly on speaking terms with his professional brethren. But here before us lies a work upon this subject of discord, which, we venture to predict, will be heartily welcomed by the whole body of English-speaking and English-reading physicians. And let us here remark, to the author's credit, that we can find in it no trace of rancor at past grievances, no hint of self-satisfaction at his own consummate triumph.

The book is a good one, both in style and in matter. It is written in plain unpretentious English, with none of those sonorous triplets and rhythmic euphuisms which flounce and trick out the ambitious literature of the day. As regards matter, from title-page to colophon we have hardly turned a leaf without finding something new, something interesting, something of value. Who, for instance, would presuppose that after the removal of both ovaries the catamenia could still continue, and that the sexuality of the woman could remain unimpaired? But case upon case is given to substantiate these curious facts. Spencer Wells, indeed, relates that after such a wholesale extirpation one of his patients became actually aggressive. Where are our physiologists? What are they at? Here is matter for them to look into! Further, Dr. Atlee gives two cases in which, one ovary having been removed, the other became so diseased as to require repeated tappings, followed ultimately by its removal; and yet each woman gave birth to a child. Truly, as an ex-Master of the Rotunda Hospital used, with a rich brogue, to say, "The spermatozoon is a varry inseenuating leetle deevil."

Much light is thrown upon the diagnosis of ovarian tumors. For their fluid contents he claims certain microscopic characteristics which are diagnostic, and, therefore, insists upon a tapping as a sure method of clearing up any obscurity. What specialist has not puzzled his brains in distinguishing between a fibrocystic tumor of the womb and a cystic tumor of the ovary? But Dr. Atlee supplies us with a ready test: "In the former affection, the evacuated fluid, being true liquor sanguinis, so coagulates upon cooling as to cling to the cup in which it is contained, even when inverted; whereas the fluid of an ovarian cyst remains quick and uncoagulable." It is always of great importance to know whether a cyst is in the ovary, or in the broad ligament; for the one is curable, the other not, without an operation. Here again our author furnishes us with a trustworthy method of diagnosis, which our limited space forbids us to transcribe. He explains the manner of discovering adhesions; gives the latest views upon the pathology of these tumors; shows how, when, and where to tap, and, in one word, throws out innumerable priceless hints, which alone would be the making of an author.

The work would certainly have been more complete had he collated, besides his own, the experience of other master-workmen in the same specialty. As a counterbalance, however, with rare candor and courage he tells his own mistakes, and also, it must be confessed, those of his friends. Among these we unexpectedly came across one of our own; but the rack itself would not extort from us any clue leading to the chapter or page.

After all this praise, it may seem like treachery to find fault. But, although we own to a grudge for the perpetuation of our unlucky blunder, we protest that we shall not follow the example of that son of Zeruiah, who said to his foe, "Art thou in health, my brother?" and then smote him under the fifth rib. Reviewers must be impartial; we shall try to be as much so as the circumstances will permit, scrupulously sheathing our thumb-lancet.

The chapter on "Pelvic Tumor and Abscess" is too short, and by no means up with the times. A phantom chapter of just nine and a half lines (we refer the incredulous reader to chap. xv., p. 348) discusses the whole subject of phantom tumors. This miracle of condensation stands unapproachable; in the material world it could have been attained only by a hydrostatic press, or by the pressure of several atmospheres.

The chapter on pathology, and the one on chemical analysis, written respectively, and very ably too, by Drs. Mears and Drysdale, are thrown so awkwardly into the body of the text as to give no clue whatever to the authors. "During the past year," begins the one, "I have had the opportunity, through the courtesy of the author, of assisting at a large number of his operations." The other one is thus introduced: "The great number of fluids removed by Dr. W. L. Atlee from patients laboring under different forms of abdominal dropsy presenting an unusually favorable opportunity for the investigation of these products of disease, I commenced, in the year 1853, their chemical and mi-

croscopical examination." Now, "Who is the first 'I,' and who the second 'I'?" will be the query of the puzzled reader, unless perchance he has done what few nowadays do, read the preface.

We are tempted to break a lance with the author on some far more practical and important points, but, before the bold crest of so tried a knight, we deem discretion to be the better part of valor. "Touch the Hospitaller's shield; he has the least sure seat," cried out the crowd at the tourney of Ashby. This cowardly advice Ivanhoe did not follow, but we shall.

A Nomenclature of Diseases, etc. 8vo, pp. 94. Philadelphia, Collins, printer, 1872.

This pamphlet has the following history: In 1869 a committee was appointed by the American Medical Association to determine what alterations, if any, were necessary to adapt the Provisional Nomenclature of the Royal College of Physicians of London to general use in the United States. This committee decided that a complete revision was desirable, and, in accordance with their views, a new committee was appointed in 1870, whose report was handed in at the meeting of the Association in May last. A minority report, signed by four members, embodied a resolution, which was carried, that the nomenclature and classification, as submitted, should be published in the *Transactions*, and that an edition of one thousand should be printed for distribution to the profession; the question of its adoption being postponed to the next annual meeting.

We commend the examination of this most important subject to our readers.

BOOKS AND PAMPHLETS RECEIVED.

The Science and Practice of Medicine. By William Aitken, M.D. Edin., Professor of Pathology in the Army Medical School. Third American, from the Sixth London Edition, with Additions by Meredith Clymer, M.D. In two volumes, illustrated. 8vo, pp. 1056, 962. Philadelphia, Lindsay & Blakiston, 1872.

On Some Affections of the Liver and Intestinal Canal, with Remarks on Ague and its Sequelæ, Scurvy, Purpura, etc. By Stephen H. Ward, M.D. Lond., etc. 8vo, pp. 260. Philadelphia, Lindsay & Blakiston, 1872.

On Cerebria and other Diseases of the Brain. By Charles Elam, M.D. Lond., etc. 8vo, pp. 142. Philadelphia, Lindsay & Blakiston, 1872.

General and Differential Diagnosis of Ovarian Tumors, with Special Reference to the Operation of Ovariotomy, and occasional Pathological and Therapeutical Considerations. By Washington L. Atlee, M.D. With thirty-nine Illustrations. 8vo, pp. 482. Philadelphia, J. B. Lippincott & Co., 1872.

The Journal of the Gynæcological Society of Boston. Edited by Winslow Lewis, M.D., Horatio R. Storer, M.D., and George H. Bixby, M.D. Vol. vi., Jan. to July, 1872. Boston, James Campbell, publisher.

New Treatment of Venereal Diseases and of Ulcerative Syphilitic Affections by Iodoform. Translated from the French of Dr. A. A. Izard, by Howard F. Damon, M.D. 12mo, pp. 73. Boston, James Campbell, 1872.

Smallpox: the Predisposing Conditions and their Preventives, with a Scientific Exposition of Vaccination. By Dr. Carl Both. Second Edition. 12mo, pp. 82. Boston, Alexander Moore, 1872.

A Nomenclature of Diseases, with the Reports of the Majority and of the Minority of the Committee thereon. Presented to the American Medical Association at the Meeting held in Philadelphia, May, 1872. 8vo, pp. 94. Philadelphia, Collins, printer, 1872.

GLEANINGS FROM OUR EXCHANGES.

Insanity and Homicide.—In the *Journal of Mental Science* for July, 1872, in connection with a review of the trial of an American, named Minor, for the killing of George Merritt, we find the following remarks on the existing state of the English law as to insanity:

"If a man, knowing in other respects the difference between right and wrong, have the maddest delusion which madness can imagine, and if he do murder, and if no direct connection can be traced by others between the delusion and the murder, then, according to the dicta of English judge-made law, the man may righteously be put to death as an example to other madmen. To absolve him from responsibility, the criminal act must be the 'immediate unqualified offspring' of the delusion. If not, though he would be held incapable of conducting his own affairs, he would be considered answerable for the act. In fact, 'the good old' rule of English law, that an insane person may be a proper object of punishment, is as binding now on English judges as it was generations ago. The influence of the delusion upon the act must be direct and positive; for if an insane person, under a delusion that some one has inflicted an injury upon him, were to kill that person, he would unquestionably be amenable to punishment as a murderer. It is the duty and within the capacity of a madman to know that it is wrong to revenge evil by evil, and that it is right to bless those who persecute and despitefully use him; and if he knows this of a real injury, he must be assumed to know it of an injury which he is under the delusion that he has sustained. The unsound mind, being nowise incapacitated from full healthy function by the disease of which the delusion is a symptom, should entirely isolate its delusion or delusions, just as prudent persons isolate a case of smallpox or other infectious disease, and should not allow it to infect the feelings, thoughts, and acts. With this exception, however, that if the insane person makes a will or does any other civil act to the prejudice of another, under the influence of a delusion that he has been injured by him, his delusion will be assumed to have infected his conduct, and his act will be voided by law. He may make a will under the influence of bad feeling springing from a delusion, and he will suffer the penalty of having his act declared null; but if he does murder under the influence of an exactly similar feeling, springing from an exactly similar delusion, his act will be declared valid, and he will get the benefit of being hanged."

Cooling of the Body under the Action of Alcohol.—The following record is derived from the same source:

"MM. Lallemand, Perrin, and Duroy mention the lowering of nearly a degree (centigrade) in the temperature of animals submitted to the action of alcohol. Edward Smith points out also a cooling of the body in the same circumstances; but already, in 1848, MM. Duméril and Demarquay had pointed out a considerable decrease in temperature in animals submitted to the action of alcohol; and in one of their experiments, they were able to record, after three hours, a difference of 9.6° in a dog to which they had administered 125 grammes of alcohol; that is, a decrease in temperature more marked than when ether or chloroform has been employed.

"We ourselves, in an experiment, have observed as much as 3.5° of decrease in animals plunged into drunkenness through alcohol, but not so affected as to be killed thereby.

"Clinical observation also furnishes us with examples not less remarkable of cooling of the body under the influence of alcoholic drinks. I am indebted to the courtesy of M. Dugnet, senior Clinical Professor of the

Faculty, for the account of a case of alcoholic drunkenness, in which the cooling was carried to its utmost limits. This was a woman, aged thirty-eight years, of vigorous constitution, who, on 3d March, 1869, at ten o'clock in the morning, was brought to La Pitié, St. Charles ward, under the charge of M. Peter. This woman, after having the evening before drunk freely, wandered into the country, to near Ivry. She passed the night under a cold and heavy rain; was observed wandering about, at three o'clock in the morning, by some country laborers. At six o'clock she was found lying in a ditch, cold and insensible.

"On arrival at the hospital, coma was complete, coldness of the surface considerable, sensibility almost *nil*, the pupils contracted, the limbs exhibited slight, slow, convulsive movements, resembling contortions, or rather a kind of *repletion* in every direction; the force displayed in these movements was considerable; the pulse was full, and regular, but slow. The temperature, carefully taken, at the moment of the visit, equalled 26° (cent.) in the axilla and vagina.

"The patient, placed in bed, was heated by means of warm bottles; she had also stimulating drinks. By degrees the convulsive phenomena ceased, the temperature of the body rose insensibly, and the patient recovered consciousness at 4.30 P.M. From this moment, all the functions became re-established rapidly, and the return to health was so complete that she left the hospital two days afterwards.

"M. Hirne, clinical clerk, took the temperature at various intervals, after the first examination, which had indicated 26°. The following is the table of its gradual rise:—

Hours.	Temp. in vagina.	Temp. in axilla.
11.30	27.9	27.9
12.30	28.7	28.6
12.45	30.4	30.
1.15	30.9	31.1
3.15	34.4	34.3
4.20		36.3

Abscess and Infarctus of the Liver and Spleen.—*Le Mouvement Médical* quotes the following conclusions from a memoir on this subject, published by M. J. Arnould, in the *Gazette Médicale*:

1. Clinically, abscesses of the liver and spleen have not the history of phlegmons; the inflammatory reaction by which they are often accompanied is irregular, and depends less upon the hepatic or splenic lesion than upon the associated disturbance of neighboring organs, such as the peritoneum or pleura.

2. Anatomically, the detritus or products of retrograde metamorphosis predominate over the phlegmonous elements, in the pus of abscesses of the liver or spleen; the neoplastic membrane of the envelope is not the result of the original plasticity of exudation-substance, but the ulterior consequence of a need of protection.

3. There are instances of infarctus of the liver or spleen, that is to say, of local hindrances to nutrition in one or more regions of these glands, dependent on capillary obstructions.

4. The coagulations of blood in the liver and spleen, met with in the inhabitants of hot countries, in Europeans especially, are primarily caused by the exaggeration, physiological under such circumstances, of the glandular nutrition of those organs, through increased vascular activity.

5. This excess of vascular activity, in itself and with the aid of the general causes of debility, induces paralyses, more or less complete, of the vaso-motor nerves.

6. In consequence of these paralyses, along with a special condition of the blood, coagulations take place, first arterial and then venous.

7. Dysentery and malarial fevers, powerful causes of glandular hyperactivity and of marasmus, are eminently calculated, without being indispensable, the former to the production of infarctus of the liver, the latter to that of infarctus of the spleen.

8. The regressive evolution, the natural termination of infarctus, may produce clinically and anatomically all the known symptoms of endemic abscess of the liver and spleen. This mechanism resolves the grave objections to the hypothesis of their simply phlegmonous character.

9. Phlegmonous hepatitis or splenitis can scarcely be conceived of as possible, especially in hot countries.

10. Direct observation proves that in many cases the softening of infarctus has been the beginning of purulent deposits resembling those hitherto called abscesses of the liver or of the spleen. This is probably generally the case in hot countries.

On Œdematous Elongation with Prolapse of the Cervix Uteri, during Pregnancy and Accouchement.—M. Guéniot (*Mémoires de l'Académie de Médecine*, 1872) gives this name to a peculiar affection met with in pregnancy. The organ is congested and swollen; its cavity is transformed into an open canal. Ulceration of the os tincæ, eversion of the vagina, thinning and flaccidity of the uterine walls, are almost constant symptoms. The causes of this alteration assigned by M. Guéniot are certain anatomical arrangements of the organ, and the mechanical conditions to which it is subjected for a long time. The results of the affection are inconvenient and distressing to the woman, and there is a tendency to abortion or to premature labor.

M. Guéniot advises the reposition of the womb, and its retention by means of a tampon and bandage, with rest in the horizontal position, and sedatives.

Disarticulation of the Femur.—The *Berliner Klinische Wochenschrift* contains an account of this operation, performed by Esmarch in Kiel, in a case of osteosarcoma of the bone.

Among other points connected with the operation, particular attention is called to the following facts:

The operator deemed it advisable to saw through the bone before disarticulating the femur. This he did immediately after cutting through the soft parts. The advantages of this are very evident. The sawing through the bone requires but a moment, and then all the bleeding vessels can be secured, thus enabling the operator to proceed leisurely to the disarticulation of the head of the femur.

In the case reported, transfusion of blood was deemed necessary, and three hundred cubic centimetres of defibrinated blood were injected into the femoral vein immediately after the operation. The result was not favorable, as the patient died on the tenth day following the operation.

The blood used in this case of transfusion was the patient's own, which had been carefully caught and defibrinated during the operation, at the termination of which the femoral artery was ligated and the femoral vein exposed, so as to permit the insertion of the nozzle of the syringe containing the defibrinated blood.

Treatment of Tic douloureux by means of Ice (W. Wentteritz: *Zur Behandlung des Tic douloureux mit Eisstreichungen—Mitt. des Aerztl. Vereins in Wien*, Bd. 1, No. 7, 1872).—In a very stubborn case of facial neuralgia in a lady, which had not yielded to any of the means applied, a smooth piece of ice was stroked gently over the affected side of the face every five minutes. The painfulness of the application is lessened by holding some alcoholic fluid in the mouth until a slight feeling of warmth is excited. The pain, which disappeared in twelve hours under this treatment, had not returned ten months subsequently.

MISCELLANY.

At a special meeting of the Medical Board of Philadelphia Hospital, held September 16, 1872, the following preamble and resolution were unanimously adopted:

Whereas, It has pleased Divine Providence to remove from our midst our friend and colleague, Dr. George Pepper, Accoucheur to the Philadelphia Hospital, we, the Medical Staff of the Hospital,

Resolve, That, while we recognize the unchanging character of the Divine fiat which has called him away, we cannot but deeply deplore the loss to the hospital, of which he was an efficient officer, and to our common profession, of which he was a bright ornament. With intellectual powers which eminently fitted him to advance the science in which his interest was so deep; with a heart filled with human sympathy; with a love of truth which was unimpeachable, and a character which was beyond reproach, he was peculiarly fitted to discharge the responsible and delicate duties of his calling.

These qualities endeared him alike to his patients and professional brethren, and make it a double loss to science and to humanity that he has been removed by death just as he had fairly entered on the active duties of life. Harrison Allen, M.D.,

Sec. Medical Board.

The late Professor Edward Parrish, of the Philadelphia College of Pharmacy, who died on the 9th ult., at Fort Sill, Indian Territory, of typho-malarial fever, will be remembered by very many practitioners of medicine all over the country, who during their student days in this city attended his private lectures. He was the author of the well-known work, which bears his name, on pharmacy, and a man of high scientific acquirements, to all which he added a singularly pure and blameless private life.

The American Public Health Association.—We learn that a large number of medical and other scientific men have organized as the "American Public Health Association," with Stephen Smith, of New York, President; Edwin M. Snow, of Providence, and C. B. White, of New Orleans, Vice-Presidents; John H. Rauch, of Chicago, Treasurer; Elisha Harris, of New York, Secretary; Francis Bacon, of New Haven, William Clendennin, of Cincinnati, C. C. Cox, of Washington, Henry Hartshorne, of Philadelphia, Moreau Morris, of New York, and John M. Woodworth, of Washington, Executive Committee. The present number of members is ninety-five, all well-known workers in the field of sanitary improvement in the cities of the United States and Canada. The next meeting will be at Washington, in the last week in February.

The Hahnemann Medical College is said (by a Homœopathic journal) to contain a "segment of perforated ileo-cœcal and colic intestine (perforations caused by metallic quicksilver, administered in tablespoonful doses by old-school physicians)." Can such things be? We fail to see how.

Burning of an Insane Asylum.—The Northern Ohio Lunatic Asylum, at Newburg, was almost totally destroyed by fire about three weeks since. Nine persons perished in the flames. The institution contained about six hundred patients, and it is wonderful that the loss of life was not much larger.

Prizes Offered.—*Boylston Medical Prizes.*—The following are the questions proposed for 1873:

1. Electro-therapeutics.
2. The Value of Chemistry to the Medical Practitioner.

The author of a dissertation considered worthy of a prize, on either of the subjects proposed for 1873, will be entitled to a premium of one hundred and fifty dollars.

Dissertations on these subjects must be presented on or before the first Wednesday in April, 1873.

Warren Prize.—The income of two thousand dollars for three years will be awarded to the author of the best original dissertation, considered worthy of a prize, on the subject of "Experimental Researches on the Elimination of Drugs by the Mammary Glands."

Dissertations, accompanied with a sealed envelope, containing the name and address of the writer, must be sent on or before the 1st of February, 1874, to Dr. Benj. S. Shaw, Resident Physician, Massachusetts General Hospital, Boston.

Boylston Medical Society Prizes.—Two prizes, of thirty and twenty dollars respectively, will be awarded for the most approved dissertations, considered worthy, on medical subjects, to be selected by the author. Dissertations must be placed in the hands of the President of the Society on or before the 31st of January, together with a sealed envelope containing name and address of the author. Decision of the Committee to be announced at the last meeting of the Society in February.

Jacobi Prize.—A prize of four hundred dollars will be awarded for the best essay, considered worthy, on "A History of the Diseases of Infancy and Childhood in the United States, and of their Pathology and Therapeutics."

Dissertations must be sent, postpaid, accompanied by a sealed envelope containing name and address of author, to Dr. A. E. M. Purdy, 123 East Thirty-eighth Street, New York, on or before January 1, 1873.

A bequest of ten thousand francs has been made to the Academy of Medicine in Paris by M. Falret, for the purpose of founding a prize on mental and nervous diseases.

Absurd and Brutal Superstition in Connecticut.—The Providence *Herald*, Sept. 5, says, "The village of Peacedale was thrown into excitement on Thursday last by the report that two graves had been dug up near Watson's Corner, on the shore of the Saugatuck River. The family of Mr. William Rose, who reside at Saunderstown, near the South Ferry, are subject to consumption, several members of the family having died of the disease, and one member of the family is now quite low with it. At the urgent request of the sick

man, the father, assisted by Charles Harrington, of North Kingston, repaired to the burying-ground, located one mile north of Peacedale, and, after building a fire, first dug up the grave of his son, who had been buried twelve years, for the purpose of taking out his heart and liver, which were to be placed in the fire and consumed, in order to carry out the old superstition that the consumptive dead draw nourishment from the living. But as the body was entirely reduced to ashes, except a few bones, it was shortly covered up, and the body of a daughter who had been dead seven years was taken out of the grave beside her brother. This body was found to be nearly wasted away, except the vital parts, the liver and heart, which were in a perfect state of preservation. The coffin was nearly perfect, while the son's coffin was nearly demolished. After the heart and liver had been taken out, it was placed in the fire and consumed, the ashes only being put back in the grave. The fire was then put out, and the two men departed to their respective homes. Only a few spectators were present to witness the horrible scene. It seems that this is not the first time that graves have been dug up where consumption was prevalent in the family, and the vital parts burned, in order to save the living. A few years ago the same was done in the village of Moorsfield, and also in the town of North Kingston, both of course without success."

Darwin Defeated again (*Nature*, Aug. 1).—The choice of a foreign correspondent of the French Académie des Sciences has resulted in the defeat of Mr. Darwin, and the election of Mr. Loewen, of Stockholm, who received thirty-two votes, against fifteen given to the English naturalist. The discussion had extended over three long sittings in secret committee, the leader of the advocates of Mr. Darwin's claim being again his opponent in controversy, M. de Quatrefages, while M. Emile Blanchard led the opposition. A correspondent of *Les Mondes*, an eminent member of the Academy, in commenting on the result, states that not one of those who voted for Mr. Darwin shared his philosophical doctrines, and not one of those who opposed his candidature alleged as his motive the error or danger of his doctrines. "What has closed the door of the Academy to Mr. Darwin is that the science of those of his books which have made his chief title to fame—the 'Origin of Species,' and still more the 'Descent of Man'—is not science, but a mass of assertions and absolutely gratuitous hypotheses, often evidently fallacious. This kind of publication and these theories are a bad example, which a body that respects itself cannot encourage."

Alexander Pope and Physicians.—Pope always took the side of physicians. Like Johnson, Parr, and all men of enlightenment and sound scholarship, he had a high opinion of the faculty. His habitual tone, when speaking of the medical profession, was that of warm admiration and affection. In his last days he wrote in a confidential letter, "They are in general the most amiable companions and the best friends, as well as the most learned men I know."

Mortality of Philadelphia.—The following reports are condensed from the records at the Health Office:

	For the week ending		
	Sept. 14.	Sept. 21.	Sept. 28.

OFFICIAL LIST

OF CHANGES OF STATIONS AND DUTIES OF OFFICERS OF THE MEDICAL DEPARTMENT U. S. ARMY, FROM SEPTEMBER 1, 1872, TO SEPTEMBER 13, 1872, INCLUSIVE.

Brooke, John, Assistant-Surgeon.—By S. O. 105, Department of the Columbia, August 31, 1872, granted leave of absence for thirty days, with permission to apply for an extension of thirty days.

Simons, James, Surgeon.—By S. O. 137, Department of the Gulf, Sept. 2, 1872, granted leave of absence for thirty days.

Gardner, W. H., Assistant-Surgeon.—By S. O. 205, War Department, A. G. O., Sept. 3, 1872, relieved from duty in Department of the East, and to report in person to the Commanding General, Department of the Missouri, for assignment.

Cowdray, S. G., Assistant-Surgeon.—By S. O. 144, Department of the Missouri, Sept. 3, 1872, granted leave of absence for thirty days, with permission to apply for an extension of twenty days—to take effect during October, 1872.

Carvallo, C., Assistant-Surgeon.—By S. O. 89, Department of the Lakes, Sept. 5, 1872, assigned to duty at Fort Gratiot, Michigan.

Hasson, A. B., Surgeon.—By S. O. 169, Department of the East, Sept. 6, 1872, assigned to duty as Post Surgeon at Fort Trumbull, Conn.

Wolverton, W. D., Assistant-Surgeon.—By S. O. 178, Department of Dakota, Sept. 6, 1872, assigned to duty at Fort Abercrombie, Dakota Territory.

Dickson, J. M., Assistant-Surgeon.—By S. O. 154, Department of the Platte, Sept. 7, 1872, granted leave of absence for thirty days, and by S. O. 86, Military Division of the Missouri, Sept. 14, 1872, leave extended thirty days.

De Graw, C. S., Assistant-Surgeon.—By S. O. 94, Department of the Lakes, Sept 13, 1872, granted leave of absence for fifteen days, and permission to apply for five days' extension.

Sternberg, George M., Assistant-Surgeon.—By S. O. 137, c. s., Department of the Gulf, assigned to temporary charge of Medical Director's office during absence of Medical Director.

Huntington, D. L., Assistant-Surgeon.—By S. O. 169, c. s., Department of the East, relieved from duty at Fort Trumbull, Conn., and to report in person at these Headquarters.

Vickery, R. S., Assistant-Surgeon.—By S. O. 205, War Department, A. G. O., c. s., relieved from duty in District of New Mexico, to proceed to New York City, and, upon arrival, report by letter to the Surgeon-General.

Moffatt, P., Assistant-Surgeon.—By S. O 205, War Department, A. G. O., c. s., relieved from duty at Newport Barracks, Kentucky, and to report in person to the Commanding General, Department of the Missouri, for assignment.

Delany, A. S., Assistant-Surgeon.—By S. O. 205, War Department, A. G. O., c. s., relieved from duty in District of New Mexico, to proceed to New York City, and, upon arrival, report by letter to the Surgeon-General.

SATURDAY, OCTOBER 12, 1872.

ORIGINAL LECTURES.

CLINICAL LECTURE
ON CONGESTION OF THE SPINE.

BY DR. H. C. WOOD, JR.,

Physician to the Philadelphia Hospital; Clinical Lecturer on Diseases of the Nervous System to the University of Pennsylvania.

GENTLEMEN: The case which I bring before you to-day entered the wards of the hospital on the 20th of May, 1872. She had been drinking very heavily for some months, and was admitted to the "drunk-wards." The evening she came in she could walk very well. The night of the 21st, she had decided hallucinations, with sleeplessness, but these readily yielded to appropriate treatment. On the morning of the 22d the resident physician, Dr. Levy, first noticed the existence of paralysis, which he says deepened until the 24th, when it became stationary. She herself declares that she began to lose power over herself on the 21st, and by the 22d or 23d was completely paralyzed. When I first saw her, on the 26th, she lay in bed, calm, collected, with no psychical or constitutional disturbance whatever. There was no difficulty of respiration. The muscles of the face and neck were normal. The arms were completely paralyzed, but she could move the fingers of the left hand; in the right nothing stirred at her will. The right leg was completely paralyzed, but when lying in bed she could raise the left leg clear. There was some anæsthesia of both legs, but especially of the right, as tested by the compass-points. She complained of no decided pain, only heaviness and numbness in the limbs, and a feeling as if they were asleep. There was little or no back-ache, no sensation of a tightened cord around the waist. There had been no spasms whatever, except in the left leg, in which occurred occasional jerking movements, especially when excited by touching, tickling, or electrical excitement. The urine could be retained for short periods of time, but her bladder had to be frequently evacuated, or else she had involuntary discharges. The bowels were very costive. Reflex movements were very much lessened, except in the left leg, where they seemed to be heightened. The muscles were everywhere soft and relaxed. The pupils were natural.

About a week after her seizure, an electrical examination of her muscles gave the following results:

In the left leg, with primary currents (currents of the first coil of Duchenne), the response of the muscles was feeble, unless a strong current was used, and then the action was not so strong in the right as in the left leg. Through some strange omission, nothing is said in the notes as to the condition of the muscles of the arms at that time; but on the 17th of June it was noted that the muscles of the right upper arm failed to respond to the strongest induced current (probably primary current).

When this case presented itself, the first thing was to decide the nature of the attack. A very brief review of the history convinced me that the lesion was spinal, not cephalic, or, in other words, that the cause of the paralysis was in the spinal cord and not in the brain. The fact that determined this decision was the absence of any symptoms of brain palsy, such as disturbance of special sense or psychical functions. It was also apparent that there was no serious trouble in the spine above the origin of the fourth cervical nerve, as respiration was not seriously disturbed, and the function of the phrenic nerve, whose chief roots are the third and fourth cervical nerve, was not interfered with.

Moreover, it was equally plain that there was not any deep disorganization of the cord, for, whilst the motor functions of the brachial plexus—that is, the motor functions of the spinal nerves from the fifth cervical to the first dorsal—were almost abolished, the pupils were in no way abnormal. The vaso-motor nerves which supply the pupil have their origin in the region just spoken of, and the complete performance of their function was evidence not only that they were intact, but also that there was no disorganization of the cord.

The points in the case to be prominently borne in mind in making the diagnosis were:

1. Suddenness of onset.
2. Universality of motor paralysis.
3. Partial sensory paralysis.
4. Absence of all symptoms of irritation of the cord, such as spasms, or shooting pains in the limbs.
5. Absence of disorganization of the cord.
6. Absence of constitutional symptoms.

A glance at these, the main points of the case, showed that the disease could not be either acute meningitis or acute myelitis. Both of these affections are marked by intense suffering, fierce shooting pains, cinctures of intolerable anguish; in both there are also symptoms of motor excitement, such as spasms of the muscles of the arms and limbs, opisthotonos, general tetanic phenomena; and they also have, in common, fever and other symptoms of grave constitutional disturbance.

These affections having been laid aside, the next question which presented itself was, Has the patient hysteria? I decided not, and for these reasons: There were no other symptoms of that hydra-headed disease—no drooping eyelid, no craving for sympathy, none of the slight indications which betray the psychical disorder. Further, I have never seen hysterical paralysis so universal. Paraplegia from such sources is not very uncommon, but general persistent paralysis I have never witnessed. Again, in hysterical paralysis, according to Moritz Meyer, the electro-muscular sensibility is soon partially or completely lost; but our patient complained with sufficient bitterness when the galvanic current was applied to her limbs.

Another explanation of the case that offered itself was, that there had been hemorrhage into the cord,—an apoplexy of the cord brought about by the abuse of alcohol. This supposition was also rejected, not because such accident is almost infinitely rare, but because it seemed impossible that a hemorrhage

sufficient to have caused such grave disturbance should not be followed in a few days by unmistakable evidences of spinal disorganization.

By this reasoning we laid aside, one by one, all the acute diseases of the spinal cord, except that known as *congestion*.

Now let us consider in detail the phenomena of this affection, and see how far they agree with those offered by our case.

The cause of the disease, according to authors, is diverse. Ollivier assigns suppression of the menses or other discharges, as a frequent cause, and in this has been followed by most subsequent authorities. Hammond states that he has seen several cases apparently due to long standing; Radcliffe and others speak of venereal excesses; but all authorities appear to agree that one of the most common causes is exposure to cold, especially lying upon the back on the cold ground. It was just such an exposure which produced the attack in our patient. In her drunken unconsciousness, she lay upon the ground and in the wet, reckless of consequences.

The onset of this disease is very generally sudden. Rarely it may happen that the paralysis develops only in the course of one or even more days, but in the majority of instances it comes on with great rapidity and abruptness. Thus, Ollivier details the case of a lady who, when her menses were due,—their coming had been announced by the usual symptoms,—took a cold bath in the morning, and whilst dining out the same afternoon suddenly felt paralyzed; and Hammond tells of a lawyer whose long, labored speech was brought to an abrupt close by a similar incident.

In the present case, there had been, according to the statement of the patient, indications of spinal trouble for some two or three weeks. She says she had for a long time drank on an average over a pint of the commonest whisky daily, and it seems impossible to decide how far the weakness and stiffness in the legs, the intense itching of the skin, the pricking and numbness of the fingers, were really due to threatening spinal congestion, and how far to the exhaustion of prolonged over-stimulation of the nervous centres. Be this as it may, she could walk well enough when she entered the hospital, on the evening of May 20. On the night of the 21st she had marked hallucinations, with sleeplessness, which readily yielded to appropriate treatment. On the 22d, the attention of the resident physician, Dr. Levy, was first called to the existence of the paralysis, which he states was not so complete at that time as when I first saw her—on the 24th. She herself states that the paralysis developed almost entirely during the day and night of the 21st.

It is evident then that, in the case under consideration, the attack, though exceedingly rapid, was not so absolutely sudden as in some cases.

In the fully developed affection a primary fact is the total absence of fever or other general constitutional disorder. The symptoms are purely local in their character. The paralysis is distinguished by its being very general, but often incomplete, as well as, according to Radcliffe, by its coming irregularly, creeping, as it were, from limb to limb. The bladder and rectum very often are not affected, but, although some authorities assert to the contrary, they certainly are in some cases involved. In the case before you, the patient was able to retain her urine for a time, but if she had not opportunity to empty her bladder frequently, she had involuntary discharges from it.

The disturbances of sensation are less marked than those of motion. Radcliffe asserts that there is no anæsthesia or numbness, but Hammond is certainly right in stating that, although there may be hyperæsthesia in some cases, yet anæsthesia is not rarely present. There was certainly in our case a very decided but far from total loss of sensibility, with a pronounced feeling of numbness.

Reflex movements are never intensified, and, in most cases, but slightly affected, but in the present instance were very much diminished; the spinal cord seemed to have almost lost its power of answering peripheral irritations.

Pain is never a very prominent symptom. Sometimes the patient complains of a dull aching in the back, increased by a recumbent posture, or by the application of warmth. It was somewhat remarkable that in the present case this aching was not complained of until a marked improvement had occurred in the symptoms.

When pains in the limbs do occur, they are to be distinguished from those of myelitis and meningitis by being less severe, and by not being aggravated by motion. Tingling, formication, and the minor symptoms of æsthesiodic disturbance, are very common.

In our case no record was kept of the temperature of the limbs, but according to Hammond it is generally lowered, owing to vaso-motor paralysis.

The disorders of nutrition are not nearly so marked as in acute myelitis. Bed-sores I have never seen, but they are asserted to form in some cases. The electro-muscular contractility, although in severe cases diminished, is often only slightly so, and is very rarely totally lost in any muscle or group of muscles. When it is so, I think we are justified in asserting that there has been in such cases an effusion, which has produced serious organic changes in the portions of the spine which supply the affected muscles.

Quite recently Dr. Mitchell has noticed that the growth of the nails is arrested in hemiplegia, and I consequently stained the nails of this patient early in her attack. There certainly was a *partial* arrest of growth in the nails, especially in the right hand, which was much more deeply paralyzed than the left. Up to the 10th of June, the nails of this hand had scarcely grown at all; then, however, they began to grow with more rapidity, but still much more slowly than those of the other hand.

The course of the case is ordinarily favorable; after a more or less lengthened period of time, the symptoms usually yield to appropriate treatment, and recovery takes place. Sometimes, however, the paralysis deepens and the case ends fatally; generally this happens, if at all, within a few days or weeks from the beginning of the attack.

The mode of death is by asphyxia from paralysis of the respiratory muscles.

There can be no doubt that the affection which we have been considering is a distinct one, separate from its allied diseases. Death from it is comparatively rare, and but few autopsies have been reported. In those which have been recorded, there have been no marked changes discovered in the cord itself, but the vessels outside of the cord have been found in a high state of engorgement, and in some instances there has been apparently a very decided serous effusion. In a case reported by Ollivier, it is expressly stated that it was chiefly the plexus of veins lying between the vertebral column and the dura mater which were affected.

The symptoms are evidently simply the result of pressure on the cord. Ollivier accounts for the fact that the motor elements are much more disturbed than the sensory, by anatomical reasons. He says the anterior portion of the cord is always kept close to the posterior face of the vertebræ by the spinal roots, whilst the posterior portion is five or six lines from the corresponding face of the canal. The result of this is that liquid interposed between the cord and canal exerts much more pressure upon the anterior than the posterior part of the cord. At the same time, there is also a congestion of the vessels of the pia mater, and this effort of dilatation acts almost exclusively upon the anterior face of the cord, on account of its being so close to the resistant vertebræ. Hence the anterior columns especially suffer compression.

I think that there is some force in these facts, but we now know that the sensory impressions are chiefly transmitted through the gray matter, which, being situated near the centre of the cord, must be the last portion of it to feel the effect of external pressure.

ORIGINAL COMMUNICATIONS.

CYSTIC ENCEPHALOID OF THE OVARY AND OMENTUM.

BY A. C. W. BEECHER, M.D.

MRS. A. E., æt. 26 years, married, has one child. She is small in stature, and delicately built; her health has been delicate from her childhood.

February 6, 1871, I was called to see her, and found her suffering from sharp pain in the right hypochondriac region, which prevented sleep, and destroyed her appetite. She informed me that about two weeks before, having some snow on the soles of her shoes, she slipped upon an oil-cloth in the house, and received a severe fall, bruising her face, and producing ecchymosis about the right eye, and on the right side of the chest and abdomen. The fall was followed by unconsciousness for a short time. For the two weeks succeeding this accident, she coughed up blood, varying in quantity and attended with considerable pain.

The urine was dark-colored and turbid; there was difficulty in micturition and in defecation. Most of these symptoms had subsided when I first saw her. Suffering had left its impress upon her countenance. Hypodermic injections of morphia, with hydrate of chloral internally, produced only temporary relief from pain. Tonics and nutritious diet were directed for support. A frequent sensation of nausea was guarded against by lime-water. She continued in some comfort for several weeks, but confined to the house. The pain in the right side continued, and was aggravated by pressure. Hepatic dulness seemed about normal. The abdomen then began to enlarge as in ascites, not rapidly, but gradually, and palpation showed the existence of fluid, which did not materially lessen in quantity under the use of diuretics. The return of pleasant weather enabled her to take some out-of-door exercise. She also left the city for a short time, but an aggravation of symptoms induced an early return. I found the abdomen increasing in size, the pain continuing, and the constipation only relieved by cathartics. The superficial abdominal veins were very much enlarged.

September 11, Dr. J. M. Da Costa saw her, and diagnosticated a solid tumor of no small dimensions in her abdomen, in addition to the fluid. It seemed to extend from the margins of the ribs to the umbilicus, and, as it was not connected with the liver, there being diminished hepatic dulness and no splenic enlargement, its character was decided to be peritoneal growths with ascites from pressure, or ovarian tumor. A subsequent digital examination per vaginam failed to show any uterine or ovarian involvement, there being the usual free motion of the organs. Her abdomen at this time measured 39½ inches in its largest circumference. She was much emaciated from pain, loss of sleep, loss of appetite, and the great weight. As she had been nursing, there had been no catamenial discharge. Hydrarg. chlor. corros. gr. $\frac{1}{24}$, and infusion of scoparius, had been given for some time, as suggested by Dr. Da Costa, but with little benefit. She continued growing worse, particularly as to the abdominal enlargement.

December 11.—Dr. Da Costa again saw her. Emaciation had increased very markedly; greater tenderness on pressure of abdomen, which now measures 43¾ inches. She has much shortness of breath, caused by the pressure upwards of the tumor and fluid. Cannot lie down to sleep, from a sense of suffocation. The tumor is now regarded as malignant. From this time she grew worse rapidly, all the symptoms being aggravated. Anodynes had no effect, except in large doses.

January 16, 1872.—She died from exhaustion, having shown remarkable tenacity of life.

Post-mortem examination, made twenty-four hours after death.—Countenance bore expression of long suffering; body exceedingly emaciated; superficial abdominal veins very much enlarged, and the skin and subcutaneous tissue over the line of their courses deeply ecchymosed; abdomen measured 45 inches in circumference. A longitudinal incision was made in the median line, extending from the ensiform cartilage to the pubic symphysis. Bloody serum, containing a pinkish, shred-like material, was removed to the amount of

three gallons. The tumor was adherent to the anterior abdominal walls over a surface 15 inches in diameter, and dissection was required to separate them. Posteriorly and laterally, the tumor was entirely free; superiorly, it was attached to the omentum, which was almost entirely involved in the growth; and inferiorly, to the left ovary, which was entirely lost in the tumor, no trace of ovarian tissue being detected upon careful subsequent dissection.

Though in one large envelope, the tumor was lobulated and cystic in character; the cysts did not extend entirely through it. The incision in the linea alba opened a cyst from which was taken a small quantity of bloody fluid, with a large quantity of shreds of broken-down tissue. The other cysts had similar contents. The tissue in the solid lobes was of a yellowish-white color, and not very firm; it resembled cerebral substance. The cyst-walls were thick and dense, varying from ¼ to ½ inch. The veins running through the tumor were enormously distended, and capable of admitting the little finger.

The left Fallopian tube was stretched to seven inches in length, and its calibre wide enough to admit a large uterine sound. It lay close along the inferior portion of the tumor, and was not involved, being freely movable along its entire length. The tumor was 18 inches in its longest diameter, 15 inches in width, and nine inches in thickness, and by actual weighing was 25 pounds.

An examination of the specimen by Dr. Da Costa determined it to be cystic encephaloid of the ovary and omentum. The specimen is now in the Jefferson College Museum.

The liver was somewhat contracted and pale in color; the spleen was about normal in size and color. The kidneys were pale, but presented no marked degeneration. The other cavities of the body were not examined.

In making the examination I was assisted by Dr. William H. Webb, who also saw the patient with me several times during life.

TRANSLATIONS.

A FEW REMARKS UPON THE RELATION OF HÆMOPTYSIS TO PULMONARY CONSUMPTION.

Translated for the *Philadelphia Medical Times* from the German of Professor Felix von Niemeyer.

BY HAMILTON OSGOOD, M.D.

THREE years ago, through my assistant, Dr. Ott, I published, in the *Berliner Klinischen Wochenschrift*, a series of clinical lectures upon pulmonary tubercle and pulmonary consumption, beginning with the following words:

"No doctrine in the whole range of pathology demands a thorough reform so urgently as the doctrine of pulmonary consumption. In this direction, clinical medicine has become completely superseded by pathological anatomy. The expression 'tubercle of the lungs' is still the most frequently-used designation for consumption of the lungs; a proof that the majority of physicians and clinical teachers of to-day hold fast to the stand-point of Laennec, and recognize only *one* form of consumption, viz.: tuberculous consumption. The dangerous assertions of Laennec, that '*pulmonary consumption is a constitutional disease, which can never develop itself from an acute or chronic pneumonia, never from a bronchial hemorrhage, never from a neglected catarrh,*' are even now repeated from the lecture-chairs as incontestable truths, and, in practice, exercise upon the prophylaxis and treatment of consumption the most prejudicial influence."

The thorough reform of the theory of pulmonary consumption, which three years ago I indicated as being so urgently necessary, was not long in coming. The views of physicians respecting the relation of pulmonary tubercle to pulmonary consumption have since that time undergone an almost entire change. To-day, the above-quoted opinion of Laennec, which three years ago was perfectly allowable, and the correctness of which was at that time denied by nobody, is no longer accepted. I may be permitted to maintain that my clinical lectures, which met with an uncommonly rapid and wide-spread reception, and which were soon followed by the excellent works of Hoffmann, Colberg, Waldenburg, and others, contributed essentially to this change, as well as to the clinical value of the works of Virchow and Buhl, which by practitioners have for years remained almost unnoticed.

But few passages of the mentioned publication have experienced serious attack. Indeed, even the assertion that "*the greatest danger of most consumptives is that they may become tuberculous,*" which at first, from various sides, was designated as going too far, or as whimsical, after having received, through countless experiments upon animals, a weighty confirmation, is now almost universally recognized as perfectly correct. Only in respect to the relation of pulmonary and bronchial hemorrhage to consumption of the lungs is the correctness of my views disputed, and in this instance by a weighty authority,—Geheimrath Traube, of Berlin.

Traube, apparently, does not share the opinion that under certain circumstances the product of acute or chronic catarrhal pneumonia, and in some cases also the product of croupous pneumonia, undergoes a cheesy metamorphosis. He evidently still holds fast to the old theory, according to which one must, from the cheesy metamorphosis of the infiltrates, which have been the result of a certain kind of inflammatory process, infer the "tubercular nature" of the same.

Under the title "A case of acute tubercular (cheesy) pneumonia with rapidly fatal termination," Dr. Fräntzel published, in 1867, the following case, including observations by Traube:

A clerk, æt. 28, who claimed to have been previously healthy, experienced on the 24th of May a severe attack of chills. This attack was succeeded by constant fever and cough. Several days later, spitting of blood set in, which became so considerable as to lead the patient to seek admission to the Charité. Here it was found that the body-temperature was 40.1° R., the pulsations 100, the respirations 48. Examination of the chest discovered a marked and extensive condensation of the left lung, and abundant râles in the same, but no bronchial respiration. The spitting of blood continued, as did the fever; the respirations increased to 60 in the minute; the patient began to be delirious, and at length insensible. Collapse set in, and on the seventh day after his admission to the hospital, and thirteen days after the attack of chills, the patient died.

Autopsy.—Excepting several old, indurated nodules, and a few smooth-walled cavities of the size of cherry-stones which were found in the apices of *both* lungs, the autopsy revealed simply a very extensive lobular infiltration of the entire left lung. Within the firm,

grayish-red, granular, hepatized localities were, here and there, found nodules from the size of a pea to that of a bean, which were undergoing cheesy metamorphosis. In the right lung were also found small, scattered, clear grayish-red hepatized spots. *In no place did the bronchia contain either fresh or old blood-clots.*

That in this case the pneumonia was not the result of the hæmoptysis, but the hæmoptysis the consequence or a symptom of the pneumonic process, cannot be doubted; and I do not hesitate to admit that through this case of Traube's my attention has been called to a connection between hæmoptysis and the inflammatory process which leads to pulmonary consumption, which, in my clinical lectures, as well as in the seventh edition of my Pathology, I have neglected to mention. On the other hand, however, I am far from believing with Traube, in spite of his rich experience, and his gift of keen observation, that those cases in which hæmoptysis is a symptom of a pneumonic process are either abundant or form the rule. Still less do I accept his belief that the countless cases of phthisis which, according to the experience of every century, follow hæmoptysis, are always, or even generally, dependent upon the progress of that process which lays the foundation of the hemorrhage,—let one designate it tubercle or tubercular pneumonia, as he will.

In my earlier experience only *one* case fell under my notice which conforms to that of Traube's patient. The parallel is very striking. I speak of a young theological student from Switzerland. In his case, severe fever and other pneumonic symptoms appeared synchronously with the hæmoptysis, and accompanied the same to the fatal end, which occurred in the middle of the second week, it having been impossible to check the hemorrhage. In the last days of his sickness the patient fell into a furious delirium. The post-mortem discovered, in both lungs, pneumonic infiltrations, which when cut showed an indistinctly granular surface, without indications of cheesy change. *The bronchial tubes were perfectly free from coagula.*

Since Traube's case became known to me, I have noted with greater exactitude than formerly, in every case of hæmoptysis which I have had opportunity to observe, the presence or absence of fever and other pneumonic symptoms, and especially the time when the hæmoptysis took place. In only one case, however, has it appeared to me probable that the hemorrhage was a symptom of a pneumonic process. In every one of the remaining cases, the fever and inflammatory indications failed either during the entire course of the hemorrhage, or at least in the first days of the same. In the case of a young Swiss physician who was attacked by an hæmoptysis of rather severe character, the body-temperature while the patient remained in my charge did not exceed 37° R. He went home several days after cessation of the bleeding. There, without experiencing a return of the hemorrhage, he was seized with pleuritic pains; whether the pains were attended with fever, and what the later history of the invalid was, I have not learned.

The rare cases of pneumonia which are connected with a capillary hemorrhage of such abundance as to come under the head of hæmoptysis, appear, therefore, to be especially dangerous, because the infiltrations to which they lead possess an eminent inclination to cheesy metamorphosis. But we have no reason to refer the frequency of this issue to any peculiarity of the pneumonic process. The profuse admixture of blood in the inflammatory product is amply sufficient to show that the infiltrate is liquefied and absorbed only with difficulty, and that it frequently degenerates into cheesy metamorphosis. *Cæteris paribus*, a more unfavorable prognosis is made, and one may fear that the disease will not terminate in a breaking up of the deposits, when the sputa of a croupous pneumonia, instead of the yellow-brown tint, exhibit a color similar to that of plum-sauce. In a hemorrhagic infarctus it is precisely the rule that the originally dark-brown nodule, by a lengthened process, becomes yellow and cheesy.

With the exception of that rarely occurring hemorrhagic pneumonia (which heretofore I have omitted to mention) which leads to hæmoptysis, and later, through cheesy metamorphosis and the destruction of the infiltrates which have remained, to phthisis, I think I shall be able to refute with ease the objections which Traube has raised against my views touching the connection between hæmoptysis and pulmonary consumption.

The positive assertion of Laennec and Louis, viz., that even in those cases in which hæmoptysis precedes the cough, the sputa, and all other signs of pulmonary phthisis, tubercle had already a pre-existence in the lungs, has, it is true, until within a short time, been held by physicians as absolutely correct. This assertion, however, as I have long ago said, rests not by any means upon experience derived from the autopsies of fresh cases of hæmoptysis, but always upon the hypothetical argument that lung-consumption depends upon a new formation, and that this new formation cannot well proceed from blood which has flowed into the alveoli of the lungs.

The correct view is, that miliary tubercle, which, of course, very frequently pre-exists in phthisical lungs, develops itself, in the greater number of cases, only in an *advanced* stage of the disease, and that inflammatory processes in the lungs form the common point of origin for phthisis. By the side of this belief, it is self-evident that the theory against the dependence of lung-phthisis upon pulmonary hemorrhage falls to the ground. Possessing the correct view, one is no longer obliged to assume that all those individuals who, becoming attacked by hæmoptysis in the midst of apparently perfect health, immediately thereupon show the first signs of consumption of the lungs, have, before the appearance of the hemorrhage, been mistaken in regard to the condition of their health. It became pressingly necessary to submit to a new proof the doctrine which the most prominent inquirers, from Hippocrates to Laennec, omitted from their observations,—namely, that many cases of phthisis develop themselves from an hæmoptysis.

I have therefore for years followed, with the greatest possible exactitude and freedom from prejudice, every case of pulmonary hemorrhage which has fallen under my observation. In every instance, I have taken especial pains to ascertain the physical condition of the patient, both before the hemorrhage and at the beginning of the same. The experience of every physician in active practice will certainly agree with mine, viz., that those persons who have repeatedly suffered from epistaxis are later preferably disposed to attacks of spitting of blood, and that, customarily, the earlier attacks of epistaxis, as well as the later seizures of hemorrhage of the lungs, are in no way accompanied by constitutional disturbances, fever, or inflammatory indications, but on the contrary, while experiencing surprise and fright, the patients in other respects feel perfectly well. This experience led me to affirm (in a dissertation written under my supervision by Dr. Bürger*) that the morbid erosibility of the capillaries (hemorrhagic diathesis), which is especially observed in poorly-nourished, weak, delicate individuals, after a rapid growth, or other exhausting influences, leads, during childhood, to capillary hemorrhage from the mucous membrane of the nose; at puberty and soon after, preferably to capillary hemorrhage from the bronchial mucous membrane.

[Conclusion in our next number.]

* Ueber das Verhältniss der Bronchial- und Lungenblütungen zur Lungenschwindsucht.

NOTES OF HOSPITAL PRACTICE.

JEFFERSON MEDICAL COLLEGE.

SURGICAL CLINIC OF PROF. S. D. GROSS.

Reported by FRANK WOODBURY.

A CASE OF SARCOMA OF THE ILIUM.

WILLIAM P. JOHNSTON, nineteen years of age, first appeared at the surgical clinic on the 19th of last June, during the service of Dr. S. W. Gross. He was kindly sent to the clinic by Dr. Roland, of Media, who had been attending him, and regarded it as an interesting case. At that time he seemed as if he were laboring under a wasting disease, or as if his nutrition was greatly impaired. His face, which was pallid and anæmic, wore a despondent look, the result apparently of physical or mental suffering. He was thin and emaciated, and said that he was losing flesh. The affected limb was partially drawn up, the knee and thigh being semi-flexed; the knee was close to its fellow, and the foot was directed outward as in an ilio-pubic dislocation of the femur. It was also thinner than its sound neighbor, from a partial atrophy of its muscles.

He gave the following history: About one year before his appearance at the clinic, while working in a lumber-yard, a heavy plank fell upon him, striking him forcibly on the right hip at a time when he was bending forward to lift something from the ground. The injury was followed by loss of consciousness, and he was confined to his house for a week from its effects. Two weeks subsequent to this accident, an abscess formed at the spot, and discharged a large amount of unhealthy, dark-colored pus, of an offensive odor. He had apparently entirely recovered, when he caught a severe cold from exposure to a storm. This brought back the pain, which he considered at the time to be of a rheumatic nature. This was two months after the accident. This pain continued, being almost constant, but not severe, for about eight months, at the end of which time he began to find an increased difficulty in walking, and, on examining, first noticed a hard swelling of large size at the situation of the present tumor, which he thinks has increased but little since that time, but which has so disabled the limb as to oblige him to use a cane in walking.

The tumor projected posteriorly, apparently from the sacro-iliac symphysis to the anterior superior spinous process of the iliac bone, and from its crest almost to the tuberosity of the ischium. There was a corresponding tumor in front, protruding the anterior wall of the abdomen as far over as the umbilicus. The tumor was of large size, firm, immovable, elastic, with an apparent sense of fluctuation at one point. The skin was natural in appearance, was not adherent to the mass, and there were no enlarged subcutaneous veins. There was preternatural heat in the part, which was evidently several degrees warmer than the opposite side of the body. The tumor was smooth, not tuberculated or nodulated, and gave but little pain, which was more of a dull and aching than of a sharp or darting character. The following measurements were taken over the tumor, and contrasted with those on the opposite side:

	Over the tumor.	On opposite side.
Diagonally, from the posterior superior spine of the ilium to the great trochanter . .	11 inches.	7 inches.
Transversely, from the spinal process of the sacral vertebræ to anterior superior spinous process	11½ "	11 "
Vertically, over the most prominent portion of the tumor from about the centre of the crest to the tuberosity of the ischium	13½ inches.	11 inches.
Around the body, from the sacral vertebræ to the median line in front	18½ "	16 "

His appetite was good, the digestive functions were well performed, he had no headache and slept well.

September 7.—He appeared again at the clinic. The tumor had evidently increased in size, but did not exhibit any tendency to ulceration. His general health remained good, although he was still losing flesh.

Prof. Gross examined the patient. The tumor, which was quite solid throughout, extended nearly to the ischial tuberosity, and was the seat of a constant aching pain. A number of enlarged glands were found in the groin above Poupart's ligament.

The lecturer said, "The original injury may or may not have influenced the production of the disease. The affection might have presented itself in the part if the accident had never occurred. Patients often ascribe a supposed origin to diseases with which they could not have the slightest connection. Too much reliance must not be placed on the statements of patients, as they may mislead, even when not made with that intention; although the contrary is frequently the case, especially in diseases of a venereal origin.

"What is the nature of this tumor? The skin above it is natural and not adherent, the subcutaneous veins are slightly enlarged, but not so much so as they generally are in the variety of carcinoma known as encephaloid, which obtains its name from the resemblance it bears, on section, to the human brain, and is for the most part soft and elastic in consistence. This tumor is dense and firm; it is, therefore, not encephaloid. It is not scirrhus, because I have never seen scirrhus attain such a bulk; it is generally small, and occurs most frequently in the mammary gland and uterus, and in the liver, anus, and rectum; rarely, if ever, occurring in the bones, tendons, ligaments, muscles, brain, lungs and spleen, or in the vessels and nerves. This is not a colloid tumor; for, although colloid tumors attain a large size in the peritoneum and ovary, yet they rarely occur on the surface of the body; and, even in such a case, there could exist no danger of confounding this dense, hard tumor with colloid, which is, as its name implies, of a jelly-like consistence. This is not a fatty, hydatid or fibroid tumor, nor is it epithelioma. It is none of these; it is sarcoma. But this name conveys a wrong idea of the pathology of the disease. It means a fleshy tumor, whereas it is not more fleshy than a number of other tumors to which the name might with equal propriety be applied. It is an old name which was revived by Virchow, and by him used to designate a class of tumors which are not essentially malignant, and which, until within a few years, were confounded with encephaloid disease. Sarcoma exists in a variety of forms, which have been divided according to their microscopical characters into round-, spindle-, and giant-celled, the form most commonly met with being the round-celled variety, which exhibits itself in different portions of the body. In this case I notice an enlargement of the inguinal glands, which is unusual, and which I consider a grave symptom. The glands generally become enlarged in the neighborhood of an encephaloid tumor in a state of ulceration; and accompanying scirrhus there is an enlargement and induration of the surrounding glands, which is supposed to be due to direct absorption of the cancer-elements. This, however, is rare in sarcoma. From the appearance of this tumor I should consider it as belonging to the round-celled variety. It is quite as unrelenting as cancer, and the only efficient remedy is prompt and early removal. If in the present case this disease were in its incipiency or earlier stage, I should not doubt the pro-

priety of such an operation, nor hesitate to perform it. But now this is out of the question; the condition of the patient, the ganglionic involvement, the extent of the operation,—which would involve laying open the abdominal cavity,—all forbid such interference; it would only hasten the fatal issue. Even were the operation successful, the disease would return in a few weeks either in the cicatrix or in some vital organ. We can do nothing for the patient except to try to sustain his general health; if he suffers pain, we will give him an anodyne. Pain is a direct evil, and oftentimes claims treatment, especially in cases where it interferes with health by preventing sleep or producing mental distress. You must not let your patients suffer.

"The prognosis in this case is very clear and unmistakable. We will give him no medicine, as it would be without effect except to disorder his stomach. He may take some gentle exercise every day in the open air, and get as much food and sleep as possible.

"I had a case in my private practice somewhat similar to this, during the latter part of last term. The patient was a young married man, twenty-eight years of age, who had a tumor in the calf of the leg, which I pronounced sarcomatous and carefully removed. This shortly returned, and was followed by a second operation, but when it recurred again, which it did soon after, I advised amputation. This his friends would not consent to, and, being overruled, I again cut it out, but was not successful in obtaining all the morbid structure, as it extended into the popliteal space. This was followed by another recurrence of the disease, and this time I performed Teale's amputation at the junction of the middle and lower third of the thigh. The operation was followed by extensive suppuration, but the stump finally healed. The man died a few months later, with symptoms of solidification of the left lung. I was unable to obtain a post-mortem, as the patient was a Hebrew, whose religion forbade such an examination; but I am quite certain that he died of sarcomatous disease of the lung. Notice the history. The patient had sarcoma of the leg, which repeatedly returned after apparent extirpation, showing a special tendency to the disease existing in his system. After its usual seat of manifestation was removed, it suddenly invaded one of the internal organs, and the man died—not from pneumonia, but—from a sarcomatous deposit in the lung. There was not in the last instance, strictly speaking, a return of the disease, but there was a fresh development of it in another part of the body.

"If you have the opportunity of extirpating a tumor of this kind in its earlier stage, always do so, but do not be too sanguine. There is always danger of return in some internal organ, and the chances are that the patient will ultimately perish from the disease."

MAMMARY ABSCESS.

A young married woman, 27 years old, applies for treatment for a painful swelling in the right mammary gland. She has been confined eight weeks before. The breast is swollen, tender, and painful to the touch; and the skin over the affected part is tense, hot, and discolored, and has a peculiar glazed appearance. The tumor is not diffused, but is limited to one portion of the breast, and on touching it there is a sense of fluctuation as if its contents were fluid. This is readily distinguished from the false fluctuation in anasarca and œdema.

This affection is a phlegmonous abscess of the mammary gland, commonly called, by the women, a gathered breast. I have divided abscesses into two kinds: the phlegmonous, which is acute in character, is accompanied by a high degree of inflammatory action, runs its course quickly, is exquisitely sensitive, and is accompanied by throbbing pain; and the scrofulous or strumous, known as the cold abscess from the absence of inflammatory symptoms, or chronic, on account of the slowness of its development. The latter is only met with in persons of a peculiar diathesis, who are particularly liable to phthisis and other tubercular diseases; the former occurring much more frequently, and being seen in all ages and conditions of life.

This trouble was preceded by inflammation of the gland, or mastitis, which frequently occurs during lactation, and may be due to a number of causes, the most prominent one being suppression of the cutaneous perspiration. It generally makes its appearance within the first fortnight following parturition, and exhibits itself in the shape of small lumps, which are rather hard and deep-seated, quite tender to the touch, and about the size and shape of an almond. These are inflamed lobules, and from them the inflammation may quickly extend to surrounding lobules and may gradually involve the entire gland, which becomes swollen and heavy, and the skin over it is hot, discolored, and glossy, perhaps a little œdematous. The secretion of milk is interfered with, as the galactophorous ducts are choked with the accumulated secretion. This condition if not timeously arrested passes quickly into suppuration, forming a mammary abscess. The inflammation in its early stage may be checked by mild stimulating applications, such as linimentum ammoniæ, or warm oil with laudanum. These are to be frequently used; the nurse, in applying them, standing behind the patient, and gently rubbing the lotion on the affected gland with her hand, the direction of the friction being toward the nipple. This generally softens the induration in a short time, and promotes the flow of the milk. Combined with this, the patient may be treated on general antiphlogistic principles; occurring in a plethoric person, it may be necessary to take a few ounces of blood, either from the arm, or by leeches, from the affected part. The diet must be of the lightest kind; purgatives are sometimes called for; and the breast must be supported by a bandage or sling, having the milk drawn from it several times daily.

This inflammation may pass into suppuration, forming the condition present in the case before us. The symptoms indicative of this event are an increase of deep-seated pain of a throbbing nature, and discoloration of the surface; but the most decisive diagnostic symptom is the sense of fluctuation to the touch. This condition may be accompanied by flushes of heat over the body, followed by profuse perspiration. The indications for treatment are to open the abscess by a free and early incision, to evacuate the pus and prevent it from burrowing among the fat and dissecting the lobules of the gland from each other; by this means we save structure, time, and suffering. The pus, in such a case, is generally of a cream-like consistency, of a light yellow color, with perhaps a few flakes of lymph, but always contains milk, which is evident under the microscope. The amount of pus discharged varies from an ounce up to a quart, being generally from four to six ounces.

The mammary gland is sometimes enlarged and painful from over-distention with milk, but a due attention to the symptoms will effectually prevent any one from confounding such a condition with the one just described.

After opening the abscess with a curved bistoury, a slippery-elm poultice was directed to be applied and renewed three times daily, the inflamed part to be painted with equal parts of tinct. iodine and alcohol, some laxative medicine given, and the patient enjoined to keep at rest for a few days.

DOUBLE HYDROCELE WITH CONGENITAL HERNIA.

Henry Porter, æt. 6 weeks, exhibited a distended scrotum, the enlargement extending into the lower part

of the abdomen. This tumor was first noticed by the mother when the child was two weeks old.

This affection may be hydrocele, or hernia, or both; but whatever it is, it was, without question, congenital in its origin. A hydrocele of the vaginal tunic of the testicle may exist by itself, and, in rare cases, may coexist with hernia. On examining the scrotum we find that it is much larger than it should be, and the testicle is at its lowest portion. The tumor is soft, translucent, and fluctuates, but at one part has a peculiar gaseous feel.

Hydrocele is an accumulation of a watery albuminous fluid, generally in the vaginal tunic of the testicle, but it may be encysted in the spermatic cord. It receives the name of single or double, according as it is limited to one side or exists on both. It forms a soft fluctuating tumor, which by transmitted light is seen to be translucent; it frequently occurs in children, but is also a disease of adult life. It may be simulated by a scrotal inguinal hernia, which however generally is a denser tumor, and is not translucent; it receives a distinct impulse when the patient coughs or cries, and, if reducible, returns into the belly with a gurgling noise on applying taxis. An exploring-needle, however, would settle a doubtful diagnosis, as its withdrawal would be followed by a drop of clear fluid if the tumor were hydrocele.

Congenital scrotal hernia will be readily understood by remembering the course which is followed by the testicle in its descent. This organ is originally developed, during intra-uterine life, in the upper and back part of the abdominal cavity, immediately under the kidney and behind the peritoneum, to which it is firmly attached. By the contraction of the fibres of the "gubernaculum testis," the testicle is gradually brought to the opening of the internal abdominal ring, through it, and along the inguinal canal, until, emerging from the external abdominal ring at about the seventh month of fœtal existence, it assumes the position that it occupies in after-life. In its descent it draws with it the peritoneum, forming a funnel-shaped process extending through the inguinal canal to the testicle. Generally the sides of this peritoneal canal grow together shortly afterwards, and degenerate into a fibrous cord, thus obliterating the cavity; but nature sometimes fails to do this, and the communication remains open, and when the child cries the bowel is forced down, forming oblique inguinal hernia. This is called congenital hernia. Now, if hydrocele also exist, the fluid, by pressing on the tumor, might readily be made to recede into the peritoneal cavity through the abnormal opening. In the case before us, both conditions are evidently present. The watery, fluctuating part of the tumor is the fluid contents of a hydrocele, and the denser, gaseous portion is undoubtedly a loop of intestine.

A less careful diagnosis here might have destroyed the child's life; either from an incautious puncture of the bowel, or, by endeavoring to cure the hydrocele by adhesive inflammation, the morbid action might readily extend by direct continuity of structure and produce fatal peritonitis.

To promote absorption of this fluid, a weak solution of hydrochlorate of ammonia in water (grs. x to f℥j) will be used,—a cloth wet with this shall be kept constantly to the part. Treatment for the hernia must be deferred until the child is a little older. He is too young now to wear a truss, as his skin is too delicate and tender, and the pressure would irritate it. It would also be impossible to keep such an apparatus clean. For these reasons a truss should never be ordered for a child so young, as its use may be dispensed with for a few months, with advantage to the patient and comfort to his attendants.

A NEW edition (the third) of the "Philadelphia Medical Register and Directory," will soon be issued.

WILLS OPHTHALMIC HOSPITAL.

SERVICE OF H. E. GOODMAN, M.D.

Reported by CHARLES K. MILLS, M.D.

EXTRACTION OF CATARACT BY LIEBREICH'S NEW METHOD.

G. R., æt. 77, in his right eye presented a good example of an amber-colored, senile cataract. The left eye had several months previously been operated on successfully by Von Gräfe's modified linear extraction method.

On consultation, it was decided to extract, and after the patient had been in the hospital two days, the following operation was performed, the pupil having been strongly dilated with atropine. The patient was placed upon his back; no anæsthetic was administered. Dr. Goodman stood behind the head of the patient, and carefully elevated the upper eyelid with the index finger of his left hand, steadying the eyeball by gently pressing the middle finger against the inner canthus. In his right hand he held a small Gräfe knife, with its back horizontal and backwards, the plane of the blade making with the horizontal meridian of the eye an angle of about 45°. With this knife he punctured the sclerotic about one millimetre behind the corneal margin, and at a point two or three millimetres above a line drawn horizontally from the upper pupillary margin of the iris. The knife was then passed straight across through the anterior chamber, and brought out at a point corresponding to that of entrance, namely, in the sclerotic, but as close as possible to the sclero-corneal junction. Pushing the knife forward gently, and then retracting it, he finished the incision, after which the eyelid was allowed to drop carefully. Liebreich generally makes his incision below the pupil, although he states that it can be made either downwards or upwards, as in the case we are reporting, according as the surgeon operating may prefer.

The upper lid was again elevated carefully, a cystotome was introduced through the opening in the cornea, and the anterior capsule of the lens was lacerated.

Iridectomy was not performed.

The upper lip of the corneal wound was now depressed slightly by means of the index finger of the left hand, and gentle pressure was made upon the cornea beneath the wound by a tortoise-shell Daviel's spoon, when the lens placed itself in the opening, and by a little additional pressure above and below was entirely expelled. By gently rubbing and pressing upon the closed lips, some remaining cortical matter was removed. The pupillary margin of the iris having entered the wound, it was carefully pushed back by means of a curette, when the pupil became round. An eight-grain solution of sulphate of atropia was instilled, a bandage with a compress of lint was lightly applied, and the patient was put to bed.

At the time of making this report, ten days after the operation, the patient is still in the hospital, and is doing well. A strong solution of atropine has been instilled twice daily. He has no considerable pain or inflammation in the eye, the corneal wound is healing finely, and the cicatrix is not easily seen at a short distance. He has sufficient vision to promise eventually a good result in this respect.

Dr. R. J. Levis, one of the surgeons to the hospital, has operated by this method of Liebreich upon fourteen cases of cataract, with a good result in every case.

PROF. NÉLATON.—Private advices announce that the health of this distinguished surgeon is much improved, if, indeed, the accounts of his illness were not from the first considerably exaggerated. It is to be hoped that both statements are true.

EDITORIAL.

OUR DEALINGS WITH THE INSANE.

IT would be idle to deny that great defects exist in the present system of management of the insane, or at least in its practical working in this country. The subject is one of such magnitude that anything like a discussion of it here would be out of the question; but we would urge certain points on which, in the light of recent developments, the necessity of reform seems most pressing.

And first, as to the profession at large. The curriculum of every medical school should include the study of the diagnosis, and to some extent of the treatment, of mental disease; not merely as a branch of medical jurisprudence, but as one of the qualifications for the ordinary practice of the profession. Every physician should have such a knowledge of insanity, of its physical and psychical symptoms, as to enable him to recognize it and its counterfeits; as to enable him to say intelligently what are the prospects from medical or moral treatment, and to judge whether removal to an asylum is or is not necessary.

Secondly, as to the process of placing the insane under restraint. Unless the legal forms are disregarded, it would seem that ample securities are provided to insure the admission of none but suitable cases into our hospitals. An unnecessary multiplying of difficulties would work evil, and perhaps very great evil, in the other direction. It may be, however, that the responsibility attaching to the giving of certificates in these cases is hardly enough realized; and the signatures appended to them should certainly be at least as carefully scrutinized and verified as those of a bank-check. We know of one instance in which a patient was taken into an insane hospital upon a certificate signed by two physicians in a neighboring State, endorsed by a physician in this city who did not know their signatures to be genuine, and whose handwriting, like theirs, was unknown to the physician of the institution.

In regard to the rectifying of mistakes and the release of those improperly confined in insane asylums, the actual fact seems to be, in the opinion of those best qualified to judge, that they are so rare that the existing provisions are ample. There would be continual appeals, attended with much needless trouble and expense, if the patients themselves were allowed to make application to the courts whenever they thought themselves wrongly detained.

Thirdly, as to our asylums. Most of these, in our humble opinion, are too large for the control, both administrative and professional, of any one person. They are in one sense too private; they are not under the inspection of any disinterested authority. On the other hand, in large institutions of the kind it is impossible to avoid much exposure of patients to sometimes ill-natured and gossiping observers.

Again, we cannot but think that far more important contributions to the general stock of knowledge on the subject of insanity ought to have been made by those in charge of our great and expensive hospitals. This, however, is in most cases rendered impossible by the pressure of daily duties.

Other topics suggest themselves, such as the proper disposal to be made of criminals shown to be insane, and the best way of providing for the care of the insane poor.

In all these matters the profession are deeply interested, and there are those among us who could speak knowingly upon them. We should be glad to receive communications bearing upon the solution of difficulties of such vital concern to human progress.

THE HOTTEST MONTH AND HOTTEST SUMMER ON RECORD.

IT can hardly be necessary to apologize for placing before our readers, in this prominent position, the following statistics, which speak for themselves:

	1871.	1872.
Mean Temperature of Eighth Month (August), per Pennsylvania Hospital . . .	78.49 degs.	81.64 degs.
Highest point attained, do. .	92.50 "	97.00 "
Lowest point during do., do. .	64.00 "	58.00 "
Rain during the month, do. .	5.97 inch.	8.31 inch.
Deaths during the month, being for four current weeks for 1871 and five for 1872 . .	1300	2146
Average of the mean temperature of Eighth month (August), for the past *eighty-three* years		73.33 deg.

Highest mean of temperature during that entire period, *this year*	81.64 degs.
Lowest mean of temperature during that entire period, 1816	66.00 "

SUMMER TEMPERATURES.

Mean temperature of the three Summer months of 1871	78.88 "
Mean temperature of the three Summer months of 1872	80.09 "
Average of the Summer temperatures for the past *eighty-three* years	73.67 "
Highest Summer mean occurring during that entire period, *this year*	80.09 "
Lowest Summer mean occurring during that entire period, 1816	66.00 "

In reference to the intense heat the above speaks for itself: "*The hottest month and the hottest summer on record.*" The nearest approach for the *month* occurred in 1863—79.50 degrees, and for the *summer* 1870—78.88 degrees. The month previous, it may be remembered, was also the hottest Seventh month ever known here, while the *Sixth* had only been exceeded *twice* during the long period of *eighty-three* years, viz., 1865, only a fraction of a degree, and 1870, about a degree and three-quarters.

While the Pennsylvania Hospital records 97 degrees as the highest point reached *there*, there were some localities in the city, very much exposed to the heat, where the mercury touched 102 degrees in the shade.

The rainfall for the past three months has been unusually large, the following table giving a statement of former years:

Summer of	June.	July.	August.	Total.
1872, . .	4.22	11.22	8.32	23.76
1871, . .	3.77	6.81	5.97	16.55
1870, . .	2.86	3.95	5.12	11.93
1869, . .	6.58	2.88	1.28	10.47
1868, . .	4.37	3.51	2.65	10.53
1867, . .	11.02	2.38	15.81	29.21
Mean, 35 years .	4.10	4.08	4.97	——

In comparing the *mortality* for the month of *this* year with *last*, it must be borne in mind that in 1872 records *five* weeks, and 1871 only four. While on this subject, it may be well to add that for the week ending 6th of Seventh month (July), *this year*, 764 deaths were recorded, while the nearest approach to it during the past twelve years, we find, by an examination of the article above referred to, to have taken place "in the week ending July 21, 1866, viz., 739."

We owe these observations to Mr. J. M. Ellis of this city.

PRAYER AS A REMEDY IN SICKNESS.

IT is stated in foreign medical journals that a proposition has been made to set apart certain wards in hospitals, the patients in which should simply be prayed for. We can hardly think that Prof. Tyndall, whose name is coupled with this suggestion, could have really given his countenance to a scheme so totally opposed to all the principles of common sense. As well might a business man expect his affairs to prosper, or a farmer his crops to flourish, by praying for success, without the use of any ordinary means. The fable of the teamster whose wagon was stuck in the mud, and who, imploring the aid of Hercules, was told first to put his own shoulder to the wheel, is familiar to every schoolboy.

These remarks are made in no spirit of irreverence or unbelief, but in the conviction that true religion asks for no miracles.

CORRESPONDENCE.

To the Editor of the Philadelphia Medical Times.

DEAR SIR,—In your last issue Dr. Peugnet replies to what he is pleased to call my "attempted philippic" upon his paper on the veratroidal alkaloids. In the beginning of this philippic, I spoke of his paper as "exceedingly interesting," and I will now add to this, in many respects, able; but I still think he is wrong in some of his conclusions, and also claim that my treatment of his article was throughout entirely respectful and within the bounds of courteous criticism, except it was in the use of the words "curious blunder," for which I now desire to substitute "error." I acknowledge that I did read the chemical portion of his essay somewhat hastily, and, by missing a single sentence, did state too strongly what I still believe, that the chemical investigation was not carried far enough to settle a disputed question.

In regard to the "curious blunder," Dr. Peugnet has entirely failed to understand the point I raised. It was *not the truth of the fact* that section of the par vagum arrests the vomiting and purging of veratria-poisoning that was questioned by me; but it *was the deduction* which he attributed to me, namely, *that therefore it is through these nerves that the alkaloids act on the intestinal tract*, that I objected to.

All these are, however, side issues, as are several others raised by him, and must be passed by without further notice, as space and time are valuable. The main issue is in regard to the physiological action of viridia. It is but justice to state that I read this portion of his paper carefully before writing the criticism, and further study of it has confirmed me in the opinion that his experiments were not sufficiently elaborate to establish his points, and that his explanation of the asserted discrepancies in our results cannot be true.

I used a principle, veratroidia, and got a certain amount of sedation. I used another principle, viridia, and got a greater amount of sedation, grain for grain. It is simple nonsense, then, to assert that the sedative powers of the latter alkaloid depended upon a contaminating portion of the former, because the less is never more than the

greater, and if the grain of viridia owed its sedative influence to a quarter of a grain of veratroidia contaminating it, then that quarter of a grain of veratroidia was stronger than the whole grain of the pure veratroidia. If this is not clear, I cannot make it clearer, unless by an equation. Let x = sedative power of a grain of veratroidia. $\frac{1}{4}x$ = sedative power of $\frac{1}{4}$ grain of veratroidia; and if Dr. Peugnet's explanation be true, o represents the sedative power of $\frac{3}{4}$ grain of viridia. Then the equation will be $\frac{1}{4}x + o = x +$ something. I would not reiterate this idea, had I not been misunderstood previously by Dr. Peugnet.

There is no use in trying to reconcile my results with his conclusions. One or the other of us did not observe his experiments closely.

Further, I assert that there is nothing at all obscure in my previous criticism in regard to the existence of paralysis in cases of poisoning by viridia.

It must be borne in mind that the experiments of Dr. Peugnet are very crude; that there was no attempt whatever at measuring the condition of reflex action; that there was no record kept of the immediate cause of death, or of the power manifested in the convulsions. Yet in Experiment XXI., he says, "a general tremor, followed by a *partial loss of power*, more marked in the anterior extremities," and in two out of the three fatal experiments, it was noted that before death had drawn near the convulsions had grown weaker, so that death was presumably not from the convulsions. With the positive results of my own much more elaborate experience too fresh in my mind, I certainly looked on these facts as indications of paralysis, and I yet believe that, in these experiments of Dr. Peugnet, paralysis was really present.

Dr. Peugnet certainly makes a vital mistake in supposing that the use of a cardiometer or some similar instrument is not necessary to the experimental study of the circulation. The mere number of cardiac pulsations is of very little moment; for every practitioner knows that an exhausted, depressed heart will often beat very frequently, especially when it is irritated by emotion, muscular action, convulsions, etc., all of which disturbing causes were present in a high degree in his experiments. I must then reaffirm my judgment that his physiological study of the action of viridia upon the circulation was not deep enough to be of any real value.

My paper on viridia was a maiden attempt at a physiological investigation, and was not as complete as it might have been, but the experiments were carefully elaborated and noted, as far as they went, and their results cannot be overthrown by experiments in which not a single one of the modern methods or appliances was used, *especially as my results are in strict accord with those of previous experimenters.* As far as I am concerned, this matter must end here. The facts are now plainly before the profession, and any further discussion would partake too much of the character of a personal controversy to suit my views.

H. C. Wood, Jr.

To the Editor of the Philadelphia Medical Times.

DEAR SIR,—Can you enable me to get out of a difficulty? Here is the position in which I am. It reminds me a good deal of one I read of when studying Renwick's Natural Philosophy, some thirty years ago. It appears that Galileo announced that bodies having the same specific gravity would reach the ground in the same space of time, when allowed to fall from a given height. To prove this, he went, accompanied by a committee of philosophers, to the top of the leaning tower of Pisa, and two stones of the same material, differing in size, were allowed to fall to the ground. They came down exactly at the same time. The committee, however, decided that they did not, *because Aristotle said they would not.* A similar yielding to authority was hardly to be looked for at the present age of the world, and in this bold country; and yet I have met with it, and wish to present it to you.

When I began to treat patients myself, I naturally used the same means, and employed them in the same way, as I had seen practised with satisfactory results by my teachers. When, however, in certain venereal cases where I had seen Ricord, Nélaton, and others give the protiodide of mercury, and the symptoms disappear, I endeavored to give it myself, I found very often the patients could not take it. I soon learned, again, that this medicine when procured at the shops of certain apothecaries, where it was either better made or better kept, could be taken without trouble, and with all the good effect observed in France.

Now, again, there are certain syphilitic symptoms that are neither altogether secondary nor altogether tertiary, but are what Ricord calls symptoms of transition.* To cause these to disappear, I was always taught that it was necessary to give the iodide of potassium, while you were giving at the same time the iodide of mercury. I had seen Ricord do this any number of times, and any one can see for himself what his opinion is, at page 629 of the work just cited. He says there, "When transition symptoms exist, from secondaries to tertiaries, . . . treatment by the iodide of potassium alone is not sufficient, and mercurials must be added. Here again, except in certain indicated cases, it is the protiodide of mercury that I prefer." I have myself reported cases, under the care of Nélaton, where the protiodide of mercury, in half-grain doses, was given in the evening, and the iodide of potassium, in fifteen-grain doses, in the morning, for weeks and months.†

Now, in these cases of transition symptoms I have for years been perfectly satisfied with the result of this treatment, *when the medicines were procured at certain shops:* those where the protiodide of mercury was good.

Some days ago I was stopped in the street by a member of a firm of apothecaries in this city, who wished to say how much he was aggrieved at my having directed a patient to cease taking these medicines, which had

* See Ricord's edition of Hunter's Treatise on Syphilis, page 580.

† See Clinical Lectures on Surgery, by Nélaton, pp. 614, 618, etc.

been procured at his shop, and were causing serious symptoms, and to have the prescriptions compounded elsewhere. The blame, he said, for the occurrence of these symptoms, was to be attached to the prescriber, and not to the furnisher, of the drugs. For his own benefit I invited him to my office, where I could show him the authorities just referred to. Notwithstanding all this, and notwithstanding his meeting in the office a patient who was then submitting to this very treatment with the most marked benefit, and with no abdominal inconvenience whatever, he left me, declaring that it was impossible to use the medicines at the same time; he had so been taught at the School of Pharmacy, and of course it was so; and, moreover, that he should refuse to put up the prescriptions, were they to be offered at his counter.

Now, Mr. Editor, while exceedingly perplexed by not being able to have a favorite prescription put up at the counter of this particular shop, and having recourse to you for help in the matter, I must own to feeling great delight at meeting with such reverence for a teacher's instructions, and such self-sacrificing scrupulousness in protecting patients from the mistakes of a physician. It is not the only instance I have myself met with of extraordinary care at this same shop. Some years since, having something to do with the appendix of formulæ attached to Druitt's System of Modern Surgery, I copied a prescription, thus:

℞ Bismuthi trisnitratis,
Pulveris acaciæ,
Sodæ bicarbonatis,
Singulorum, ℈j;
Pulveris zingiberis, gr. v.

Misce, fiat pulvis.

It was carried to this shop, and a boy employed there brought it back, saying that Mr. —— said I had forgotten to put the quantities of bismuth, soda, and gum arabic, and they had no *singulorum* in the shop.

WALTER F. ATLEE.

PROCEEDINGS OF SOCIETIES.

PATHOLOGICAL SOCIETY OF PHILADELPHIA.

THURSDAY, SEPTEMBER 12, 1872.

THE PRESIDENT, DR. J. H. HUTCHINSON, in the chair.

DR. J. H. CATHCART exhibited a specimen of *cancer of the pylorus, duodenum, and pancreas*, adherent also to the upper periphery of the *right kidney*.

The specimen was removed from M. A. B., æt. 46, who died Sept. 7, 1872; she was a widow, and a native of Ireland.

She first suffered from metrorrhagia nearly ten years ago; this at times was quite profuse, and very little influenced by treatment, but ceased some four years since, and did not return until about two months ago, when she had a slight hemorrhage, which, however, required no treatment.

She had also complained at times, for several years, of an intense burning pain in her stomach and in her back, both between her shoulders and in the lumbar region; also of swelling of her hands and face. These symptoms all yielded to treatment, so that at times she was entirely free from pain; but her appetite was very variable, and generally her digestion was fair, though she vomited occasionally after eating. For a few weeks before her death, she could retain scarcely anything on her stomach, vomiting half a dozen times a day whatever nourishment she might take, together with a dark-brown "coffee-ground"-like fluid. She presented the so-called cancerous cachexia.

On post-mortem examination, made by Dr. Porter and Dr. Cathcart, the stomach was found filled with a dark-brown fluid resembling that which had been vomited during life. The mucous membrane was pale and anæmic, and at the pylorus was a large cancerous mass which nearly closed the orifice, and involved also parts of the duodenum and pancreas; the latter being somewhat enlarged. The spleen and liver appeared normal in size and appearance. The kidneys were normal in size, but fatty, and the surface of the right one was adherent to the cancerous mass.

The womb was hypertrophied, pale, fatty, and in the cavity was found a small pediculated polypus.

The specimen was referred to the Committee on Morbid Growths, who reported that the case was one of *simple scirrhus of the pylorus*. Also that the infarctus in the kidney proved to be a simple embolic patch, the centre of which had undergone softening.

DR. C. M. CHESTON exhibited, for Dr. Packard, a specimen of *abscess of the kidney*, from W. E., white, sailor, aged 39. Was admitted to the Episcopal Hospital on the morning of the 10th of August, 1872. Stated that he was knocked off one of the coal-wharves at Port Richmond on the night of the 9th, by a couple of seamen who wanted to rob him. He admitted, however, that he had been drinking, and did not remember whether any words had passed between them before he was struck, or not. Was brought to the hospital by two policemen, who found him lying under the wharf, not insensible, but utterly helpless. Upon examination, it was found that he had fracture of both wrists (Barton's), but he had (to all appearances) internal injuries of a much more serious nature. Complained of very great pain over the region of the bladder on the slightest pressure. Shortly after his admission he passed about one ounce of bloody urine voluntarily. After this his water was drawn off for him with the catheter, but in no instance did we succeed in getting more than two ounces. Ordered morph. sulph. gr. ¼, by the mouth, in the afternoon; and, the pain being very great, the dose was repeated late in the evening. On the morning of the 11th he was more comfortable. Catheter was introduced, and we drew off about the same quantity as that passed at each introduction of the catheter on the preceding day. The pulse and temperature about normal. Flaxseed poultices ordered over the seat of pain. On the afternoon of the 11th he asked for a urinal, and passed about eight ounces of urine, tolerably clear; this he did again at seven in the evening. On the morning of the 12th he seemed quite comfortable, though the tenderness over the lower part of the abdomen still continued. The abdomen was considerably distended and tympanitic; pulse 120. He was ordered twenty-five leeches over the abdomen; verat. virid. gtt. vj in mist. neutral. ℥ss, every four hours. In the evening his pulse had risen to 135; he voided his urine voluntarily and without difficulty. August 13, he seemed quite comfortable, had less pain; his pulse 96; but at 6.30 P.M. he was not quite so well. From this date his pulse gradually rose in frequency until it reached 128. August 21, he was not so well, had more pain over abdomen and

over the region of the liver. He was also considerably jaundiced, and had some diarrhœa, with a pulse of 124. August 23, he was about the same, with a pulse of 120, diarrhœa continuing. He was cupped over the seat of the pain, and ol. terebinth. gtt. x was administered every three hours. On August 24 he seemed better; had not so much pain, and was quite cheerful. August 30, to all appearances, presented a well-marked case of typhoid fever; pulse 140. His condition was not materially changed until September 3, when he began to sink rapidly, and died September 4, at 6 A.M.

The post-mortem was made in the afternoon of the same day, when there was found general peritonitis; the peritoneum being very much thickened. The liver was very large and fatty, and weighed six pounds. The spleen was large, firmly attached to the peritoneum, and weighed two pounds. Both kidneys were enormously enlarged, left kidney particularly so, its weight being three pounds; that of right, one and one-half pounds. Both contained cysts which were filled with a purulent liquid. The intestines were healthy. The bladder was contracted, and its walls were very much thickened.

REVIEWS AND BOOK NOTICES.

PRACTICAL LESSONS IN THE NATURE AND TREATMENT OF THE AFFECTIONS PRODUCED BY THE CONTAGIOUS DISEASES; with an Account of the Primary Syphilitic Poison and of its Communicability. By JOHN MORGAN, A.M., M.D., Surgeon to Mercer's Hospital and to the Westmoreland Lock Hospital, etc. etc. Small 8vo, pp. 335. Philadelphia, J. B. Lippincott & Co. London, Baillière, Tindall & Cox, 1872.

From a perusal of the book before us, it is at once evident that Dr. Morgan has had unusual opportunities for the study of venereal disease, both in private and hospital practice; but the manner in which he has chosen to present this experience is most unsatisfactory to the reader. The volume lacks several essential elements, the most patent of which is the total absence of order and system in the arrangement of the matter presented, paragraphs and chapters being grouped with no attempt at classification. In many instances the statements are vague, and the exact meaning difficult of comprehension, while here and there through the work the same subject-matter is dealt with more than once.

Dr. Morgan professes himself a "unitist," believing that rarely, though occasionally, the soft sore may be followed by syphilitic manifestations. Decidedly the most interesting feature of the book, however, is the statement, followed by a series of experiments, that the product by inoculation of the vaginal discharge of a patient suffering from syphilitic infection, is a chancroid, or soft sore; and further, that this sore is propagated as a chancroid, and is again capable of propagation still as a soft sore or chancroid. Hence the possibility of acquiring constitutional syphilis from the vaginal discharge of a syphilitic woman, though no sore be present. Dr. Morgan is a firm believer in the proper use of mercury, and gives preference to the inunction treatment, accompanied with small doses of Zittmann's decoction. He also expresses himself in favor of syphilization. The volume is extensively illustrated with wood-cuts, some of which are emphatically poor and totally out of place in a work claiming to take a position in literature. Though the work contains much of interest and novelty, evidently the result of study and observation with a large clinical experience, yet we cannot help thinking that the author would have benefited the profession more had he taken time to arrange his material and bring out his points. That the book was written hastily is but too apparent.

THE TEN LAWS OF HEALTH; or, How Disease is Produced and can be Prevented. By J. R. BLACK, M.D. 8vo. Philadelphia, J. B. Lippincott & Co., 1872.

This work, as its title indicates sufficiently, is intended rather for the instruction of the public than for the reading of professional men. And we wish it, and the books like it, could be more widely disseminated and read. Not that we wholly agree with the writer in all his points,—for example, in his absolute condemnation of all use of tea, coffee, and tobacco,—but in the main we think his views are sound, and that the welfare of families would be promoted by the adoption of them.

The "Laws" relate to pure air, adequate and wholesome food and drink, adequate out-of-door exercise, adequate and unconstraining covering for the body, the exercise of the sexual function, place of habitation, pursuits, personal cleanliness, tranquillity of mind, and intermarriage of blood relations.

We cannot but note the excellent mechanical execution of this volume.

GLEANINGS FROM OUR EXCHANGES.

HYGROMA CYSTICUM COLLI CONGENITUM.—K. Koester (*Verhandlungen der Physic.-Medic. Ges. in Würzburg*, n. f., Bd. iii. S. 18.)

A well-formed child, born at full time, came into the world with a large tumor the size of an apple hanging from the inferior maxilla on the right side, and occupying the entire sub- and retro-maxillary region.

The tumor was covered with movable integument, and fluctuated upon palpation. The amount of transparent fluid contained in the tumor steadily increased for three months, extending from the inferior maxilla to the clavicle, and from the median line in front to the anterior edge of the trapezius muscle on the back. Since difficulty of breathing now set in, several of the sacs near the surface were opened, but only a very small amount of purely serous fluid was extracted.

The wound healed by first intention, but in six weeks phlegmonous erysipelas broke out in the cicatrix, and rapidly passed, in some parts of the growth, to suppuration, and in others to gangrene of the skin; death soon resulted from exhaustion in the fifth month after birth.

Respecting the other organs of the body, the post-mortem examination was of a purely negative character. The tumor, now as large as a child's head, had extended beyond the limits already described, had broken through the fascia superficialis colli, and completely surrounded the sterno-cleido-mastoid muscle, as well as the large vessels of the neck, which, however, were uninjured.

The deeper part of the tumor reached the base of the skull and the somewhat narrowed meatus auditorius externus, the inferior maxilla and the vertebral columns. The tumor possessed no proper capsule, but the component chambers were separated by a very delicate membrane from the neighboring tissues, into which they had inserted themselves like an infiltration.

Upon incision a large quantity of clear fluid escaped, which in the region of the purulent infiltration appeared slightly opaque and tinged with blood. The clear fluid contained a few lymph-corpuscles and a small quantity of epithelial débris, while the opaque fluid was rich in pus-corpuscles and fatty, broken-down epithelium. A section of the tumor revealed a series of spaces filled with fluid, and closely pressed together. These were varied in size from that of a millet-seed to that of a walnut, and assumed very diverse shapes from pressure. The same delicate membrane already alluded to formed the partition between the component parts of the morbid growths.

Injections of Prussian blue into the collection of cysts revealed a system of delicate connecting canals between the component parts of the tumor. An examination of a portion of the tumor hardened in alcohol revealed an epithelial lining in the larger cavities, which showed all the features of pavement epithelium upon the application of a solution of nitrate of silver. The cells, which were invisible in the simple preparation without reagent, had the form and general appearance of the endothelium of lymphatic vessels, and only here and there, in the region of the purulent infiltrations, manifested the various stages of fatty degeneration.

In the centre of the tumor there were many spaces filled with coagulated blood, which in some places appeared to be fresh, while in others it manifested the various stages of retrograde metamorphosis. Since, therefore, amorphous as well as crystalline pigment was found in the tumor, and since extravasated blood was found in the trabecular septum dividing the cavities from each other, it is evident that the case was not one of ordinary angioma cavernosum, but of hemorrhage into the cysts composing it.

The peripheral cavities grew smaller, and the interstitial tissue separating them increased in thickness; at the same time the communicating canals became coarser and were found closer together. These topographical changes produced the appearance of irregular and varied anastomosis between ordinary lymphatics. Near the centre, these cavities contained fibrinous coagulations, but towards the periphery they were empty and collapsed.

The interstitial tissues which divided the cavities from each other were composed of connective tissue, rich in fibres and cells, and contained, here and there, peculiar round nodules; these were composed of a mass of lymphoid cells, supplied with from one to four nuclei, within a delicate and vascular reticulum, which became coarser towards the periphery, and united with the trabeculæ which surrounded the larger spaces.

Koester regards these nodules as lymph-follicles, the coarse net-work at the periphery as lymph-sinuses, and the surrounding larger canals and cavities as distended lymphatic vessels.

In the region of the purulent infiltration, a large number of small round cells were found, as well as numerous large, stellate, anastomosing cells, with swollen and opaque contents.

These appearances were due to the distention of the initial lymphatics within the interstitial trabeculæ, with fibrinous and granular fatty contents from the cysts, which had been forced from the adjacent cystic cavities as a result of an overflow of their contents. In attempting to force Prussian blue directly from the cutaneous surface into the cysts, the lymphatics of the skin as well as a number of the cysts became filled with the injected fluid.

Since, however, extravasation of the coloring-matter occurred, it must remain undecided whether the coloring of the contents of the cysts was accomplished by the direct way of the lymphatic vessels or not. Ponfick, in a criticism upon the case, in the *Centralblatt für die Medic. Wissenschaften*, 20th July, 1872, says the general communication of the cavities with each other, the direct passage of the wall of the cyst into the dilated canals, and the connection of the latter with the sinuses of undoubted lymphatic glands, the continuous epithelial lining of the inner surface, the purely lymphatic nature of the fluid contents, prove beyond doubt that the case is one of distended lymphatic vessels. The tumor must, therefore, be characterized as lymphangiectasia congenita.

An Alleged Death in New York from Nitrous Oxide.—The *Lancet* thus comments on this unfortunate affair, mention of which was in all the daily papers a few months since: "We have received from New York the particulars of a case in which death speedily followed the extraction of teeth after an ineffectual endeavor to administer nitrous oxide gas. A jury of ten persons, each of whom wrote M.D. after his name, returned an elaborate verdict, commencing with the finding that the deceased 'came to her death from asphyxia or apnœa, as evidenced by the symptoms manifested by the patient before death, and the conditions found at the post-mortem, the asphyxia having, in our opinion, been induced by the inhalation of gas administered.' This is followed by certain comments or riders concerning the mode of preparation of the gas used in the case, and concerning the qualifications of persons by whom gas is administered.

"Upon such a finding, it is very possible that the case may come to be recorded as one of death from nitrous oxide; and, as the facts will by no means bear such an interpretation, it seems worth while to call attention to them in detail. . . .

"Upon the testimony, however, the facts seem to admit of only one interpretation. The nitrous oxide could have had no more to do with the fatal issue, either directly or indirectly, than if it had never been brought into the room. The patient manifestly fainted from terror, doing so as soon as her state of mental tension was relaxed by the operation being completed. Her syncope was just a result of the reaction of an overstrung nervous system; and, if Mr. Newbrough had only laid her flat on the floor, she would probably have recovered in five minutes, have paid him his fee, and have walked away from West Thirty-fourth Street as well as the entered it. It was the unwisely holding her upright that determined the fatal issue; and although one must sympathize with the queer medical jury to the extent of admitting that no anæsthetic agent should be intrusted to a man who treats syncope by the erect posture, yet still, when we consider the wide prevalence of his error, we must not be too hard on the dentist. We have lately heard of a case in which a poor woman fainted on an English race-course, and the strong arm of the law, in the person of a stalwart policeman, instantly erected her in a sitting position, with her back against a post. Fortunately, a medical man passed by in time to save her from death by laying her down again until she recovered; but the chances of her following Mrs. O'Shaughnessy were at one time fearfully great. Moreover, 'sitting up' is the most common cause of death after or during enfeebling illness. You hear from the nurse or the friends that the 'poor dear *would* sit up to take beef-tea,' or '*would* sit up on the nightstool,' and that he or she 'went off like a lamb.' We once witnessed a very sad scene, in which a group of relatives were holding up the corpse of a fine girl, who probably would have been in no danger if she had been allowed to remain where a faint had caused her to fall. Strangely enough, she was to have undergone an operation on the following day; and her death, if it had been twenty-four hours delayed, might easily have been attributed to chloroform.

"In this last circumstance—the possible coincidence in point of time of the administration of an anæsthetic with sudden death from some other cause—we have a factor that must never be lost sight of in such cases. There is one well-authenticated history of a man who went to have a tooth drawn, and asked for chloroform. The operator had none, and went a short distance to fetch it, to find his patient dead on his return.

"The absence in Mrs. O'Shaughnessy's case of any apparent cause for sudden death other than emotional syncope and the upright posture, and the entire sufficiency of these to explain the occurrence, seem to render the verdict of the New York jury one of the most

astonishing on record. It can hardly fail to be challenged by American medical journals, and we shall be curious to see what attempts are made to justify it."

A Rare Case of Vascular Anomaly (C. Aeby: *Corresp. Bl. für Schweiz. Aerzte*, Jahrg. II., No. 6).—At a post-mortem examination of an old man, the following curious distribution of vessels was found, the chief peculiarity of which consisted in the fact that the abdominal aorta gave off only two large branches instead of three. The cœliac artery and the superior mesenteric artery arose from a common trunk, which was given off at the aorta from the usual point of origin of the superior mesenteric artery. The common trunk of these important vessels was very small and thin in its central portion, but suddenly enlarged after sending off the hepatic artery and a branch which instantly subdivided into a series of small vessels to the spleen, the stomach, and the small intestines, in order to anastomose with the normal inferior mesenteric artery by means of a long arch, which followed accurately the flexura linealis and the pars descendens coli, as well as a part of the sigmoid flexure.

The immediate cause of this abnormal connecting branch between the two mesenteric arteries appeared to be an almost complete thrombosis in the narrow initial portion of the arterial trunk, produced by a calcareous and aneurismal dilatation of the aorta, which had rendered the arterial trunk almost impervious as far as the point of origin of the hepatic artery. In alluding to this case in the *Centralblatt für die Medic. Wissenschaften*, July 27, 1872, Ponfick says that a portion of this anomaly may be regarded as congenital, but that much is due to the later chronic changes in the vascular apparatus.

Hypertrophy of the Tongue (G. Maas: *Arch. f. Klin. Chirurgie*, xiii., B. 3, H.).—In the surgical clinic in Breslau, during the past year, there were five cases of hypertrophy of the tongue reported. They were all congenital in their origin; the tongue was, in some instances, affected on one side only; in others, throughout its entire structure. In one case the hypertrophy of the left half of the tongue was accompanied by hyperplasia of the entire left half of the body. All the cases were treated by means of the galvano-caustic. The microscopical investigation in one case, two years old, revealed complete hyperplasia of all the tissues of the tongue, and, in three others, new growths of connective tissue and vessels, so that the tongue was completely metamorphosed into a spongy, cavernous mass.

The least amount of tissue-changes was in a patient three years old, a greater amount in one of twelve years, and the most prolific changes had occurred in a patient twenty-one years old.

Hence the conclusion that every case of macroglossa first consists of hyperplasia, to which is added increase in connective tissue and vessels, as a secondary result of continual irritation caused by the enlarged and protruding tongue.

Anchylosis of the Inferior Maxilla cured by the formation of a false joint on each side (G. Maas: *Arch. f. Klin. Chirurgie*, xiii., B. 3, H.).—A man, 27 years old, had had in his seventh year an attack of scarlatina, which left him with an inflammation of the maxillary articulation on both sides, which was followed by complete anchylosis. Both the inferior and superior maxillary bones had suffered in consequence an arrest of development. Middeldorpf excised on one side, and subsequently Fischer on the other, a wedge-shaped piece from the inferior maxilla, the base of the wedge being downwards, according to Esmarch. The mobility had remained perfect at the time of the report, four months after the operation.

Swallowing a Fork (*Berliner Klinischen Wochenschrift*, July 8, 1872).—In the proceedings of the German Chirurgical Society, Herr von Adelmann makes the following statement:

Very lately a man in Italy has excited great interest in the public mind, as well as among the members of the profession, by having swallowed a fork. Herr von Adelmann says that he has heard of five similar cases: three occurred in France; in two of these cases, gastrotomy was performed with success, and, in one case, the fork passed out with the fæces twenty months after it had been swallowed.

The speaker then proceeded to narrate a case which occurred in Russia.

A peasant in Wiatka, during an attack of delirium tremens, swallowed a fork with a wooden handle, the whole being five inches long. For six months after this act he suffered from pain in the stomach, loss of appetite, and repeated attacks of vomiting. At last he presented himself for treatment at the hospital, when an examination revealed, between the seventh and eighth ribs on the left side, a fluctuating spot with a fistulous opening, discharging an offensive pus, and through which a metallic body could be felt.

The fork was removed by Dr. Hohlbeck from the abscess which had thus formed on the left side. After the discharge of a few pieces of the seventh and eighth ribs, the abscess healed. The patient died three months later from other causes, and at the post-mortem examination the wound of the stomach was found to be perfectly adherent to the adjacent tissues, unaccompanied by any disease in the latter.

The fifth case alluded to by Herr von Adelmann was relieved temporarily by gastrotomy; and, in conclusion, he recommended in such cases generous diet, pushed to distention, in order to allow the fork to pass more readily through the pylorus, or to cause a more rapid adhesion between the stomach and the abdominal coverings, or to prevent entirely any injury of the stomach by the fork.

It is also evident, even from the slender experience given by these cases, that secondary gastrotomy is practicable.

MISCELLANY.

New Professorship.—A Professorship of Ophthalmic and Aural Surgery has been established in the Royal College of Surgeons, in Ireland, and Mr. Henry Wilson, Surgeon to St. Mark's Ophthalmic Hospital, and Examiner in Ophthalmic Surgery in the Dublin University, has been appointed to it. This, says the *Medical Times and Gazette*, is the first of the kind instituted in Ireland.

Indian Munificence.—Under this heading the same journal announces the offer of a donation of £20,000 to the funds of the new Medical College at Allahabad, from the Maharajah of Vizianagram.

This "heathen" example is followed by Lord Cadogan, according to the *South London Press*, in "supporting the Rate-payers' Association in Chelsea against the scheme of the Local Government Board in the erection of an infirmary for that locality, at a cost of £20,000."

Sir James Shaw Willes, Judge of the Court of Common Pleas of London, committed suicide October 3, while temporarily insane by reason of the extreme suffering consequent upon a severe attack of gout.

THE NAVAL MEDICAL BOARD for the examination of candidates for admission and promotion in the medical corps of the navy, which has been in session in this city since 1868, has been re-convened in Washington, with the following officers: Medical Director Charles D. Maxwell, President; Medical Director William Grier, Medical Inspector Thomas J. Turner, Surgeons Albert L. Gihon and Richard C. Dean, members; and Surgeon Joseph Hugg, Recorder.

THE *Lancet* of July 13 says, "At an inquest held last week on the body of a French lady who died from heart-disease, a New York physician, Dr. Petitjohn, who was called as a witness, stated that for twenty years he had been coroner in New York, and that in that city the jury was always composed of six persons, a number which was found to answer admirably. Dr. Lankester admitted the effectiveness of such a plan in ordinary cases, but thought that in serious and difficult cases it was advisable to summon a jury of twelve."

A CURIOUS but by no means unusual lawsuit was lately decided in France. A surgeon extracted a piece of cartilaginous meat from the trachea of a lady, and charged her £20 for the operation. The lady considered the amount excessive, and said that Nélaton himself would not have asked such a sum. Dr. Nélaton was then appealed to, and said that, taking into consideration the position of the lady, the charge was moderate. Ultimately a jury awarded the surgeon £12.

DR. JOHN K. MASON, a well-known retired physician of this city, died on the 1st of October.

THE NEW GERMAN HOSPITAL.—The board of directors of the German Hospital have taken formal possession of the new hospital building at Corinthian and Girard Avenues, and the patients now in the old building will be removed into the new in the course of a few days. It is supplied at present with seventy-two beds, and the capacity of the institution will be increased in the spring.

IT is stated in the daily papers that on the 25th of August the wife of a physician, in the town of Canaan, N. Y., died from the effects of chloroform, administered to her by her husband for the purpose of extracting some teeth.

THE *Pall Mall Gazette* of August 15 says, "Strange scenes are to be witnessed in what Carlyle terms 'that monstrous tuberosity of civilized life, the capital of England.' That one family should collectively occupy one sleeping-room, is or ought to be a remarkable circumstance, but that ninety-two persons should sleep in three rooms is still more striking; yet it seems that such is actually the case at No 1 George Street, near Worship Street. On Tuesday a witness was called to prove an alibi in a case tried at the Middlesex Sessions,—a woman who keeps a lodging-house on the premises in question, comprising three rooms and a kitchen. In the course of her evidence it was elicited that, although no one slept in the kitchen, the three rooms were shared by ninety-two persons as sleeping-apartments, thirty sleeping in one room. Economy of space can hardly be carried beyond this point, unless people are stuffed up the chimneys, or allowed to repose in the cisterns and water-butts. The lodging-house, it was stated, is 'licensed,' and of course, if the authorities approve, there is nothing further to be said in the matter."

M. REVILLOUT, in the *Gazette des Hôpitaux*, quotes (*British Med. Journal*, May 31, 1872) certain statistics published by the French Minister of Public Instruction, in regard to the medical profession. In 1866, there were in France 11,643 doctors of medicine, being 1000 more than in 1847; while the number of *officiers de santé* was 5697, the decrease, as compared with 1847, being 2145. There was thus a total decrease of 1145 medical practitioners, notwithstanding that the population had increased from thirty-four and a half millions to thirty-eight millions. M. Revillout attributes this falling off in a great measure to the defective encouragement afforded by the State to high-class education.

A DISHONEST MEDICAL OFFICER.—The *San Francisco Post* of the 14th of August states that Dr. F. H. Engles, who has been for several years apothecary and assistant-physician of the city and county hospital in that place, but who lately resigned at the request of the Board, has been accused of systematically thieving from the hospital supplies committed to his charge. Drugs worth over $600 were offered by him to a New York house for $429.75, and suspicion was excited, which led to inquiry, and the detection of the crime.

Such breaches of trust on the part of physicians are, we are glad to be able to say, extremely rare.

THE EX-EMPRESS CARLOTTA was some months since said to have become once more violently insane, and to be failing rapidly in physical health; a favorable change has, however, again taken place in her condition.

RAILWAY AIR-CUSHIONS.—A writer to the *Medical Times and Gazette* refers to the fatigue of the limbs produced after a long railway journey as due mainly to the trembling motion of the floor under the feet, and states that, having suffered considerably from this abuse, he was induced to try the experiment of using the well-known air-cushioned footstool. This answered so well that he has never travelled without using one in this way, and has found the effect to be a remarkable improvement.

MORTALITY OF PHILADELPHIA.—The deaths reported at the Health Office for the week ending October 5, 1872, were 240; of which 118 were of adults, and 122 of minors. Among the causes assigned were:

Consumption of the Lungs	36
Other Diseases of the Respiratory Organs	29
Diseases of the Circulation	12
Diseases of the Brain and Nervous System	33
Zymotic Diseases	20
Casualties	10
Dysentery	5
Cholera Infantum	3
Old Age	10
Stillborn	15

SATURDAY, OCTOBER 19, 1872.

ORIGINAL COMMUNICATIONS.

A CASE OF ATLO-AXIAL DISEASE.

BY J. T. ROTHROCK, M.D.,
Wilkesbarre, Pa.

WITHIN a year I have had, through the kindness of a medical friend, a case of this somewhat rare disease to treat. I offer the following history for those who may be interested in it. The difficulty of diagnosis in the earlier stages of the affection, and the grave prognosis in the latter, tend perhaps to confer a value on each recorded case. Certainly, none of the somewhat elaborate descriptions I have read gave me a clear history of the *ensemble* of symptoms as I found them.

The patient was in early manhood, and had a constitution which seems to have been originally good. During the previous year, one manifestation of disease had succeeded another, until he was much reduced in strength and greatly depressed in spirits. The first trouble was of a rheumatic character, and had been well treated by his medical attendant. Immediately on recovering from this, his left foot took on an œdematous condition; then manifesting a slight sense of fluctuation, which led to the suspicion of pus. An incision, whilst it relieved the tension, failed to give exit to pus; in a word, the condition of the foot was like œdematous erysipelas. After the opening closed, a fungous growth rose from the cicatrix, and persisted for some months. At the time I first saw him, it had passed through the florid period of its growth, and assumed the pale hue of some condylomata. At the time, I thought but little of this tumor. I have alluded to these antecedents to show how much predisposed, by a lowered vitality, the patient was to a development of any disease which diathesis or accident might call into an open manifestation.

At this juncture all his troubles culminated in one still more aggravated. His neck became stiff, and so much swollen that the hollow existing in the occipito-cervical region disappeared, and there was a straight line from the occipital protuberance to the upper dorsal vertebra. For this, he went through a heroic course of cupping and blistering, along with other treatment more heterodox, under the idea that his trouble was merely local. The symptoms, however, continued with varying intensity for several months. Occasionally the patient would attribute them to a blow received when thrown headlong from his carriage some months previously, though this view was taken by him, apparently, only in the absence of any other probable explanation.

October 11, the medical gentleman in attendance, expecting to be absent some days, kindly placed him in my care, after himself seeing the patient but once or twice. The trouble being, just then, especially aggravated, was the occasion of his having requested the treatment of the medical friend to whom I allude, but who was obliged to be absent. My first impression was that, whatever the radical difficulty might be, the most urgent symptoms were those of tonsillitis. The hyperæmic condition of the fauces and the pharynx naturally led me to think this, and to act accordingly,—especially as the difficulty in swallowing was so greatly out of all proportion to any increase of pain or swelling in the occipito-cervical region.

I directed rest in bed, and a liberal course of guaiacum. In a few days the patient was out of bed, with the urgent difficulty removed, and attending to his business.

From this time I lost sight of him till October 31, when, his regular physician again being absent, I was requested to attend him.

He was now down with a fearful increase of all his previous suffering. The tonsils were enormously swollen, the half-arches œdematous to the highest degree, and the uvula, hanging down enlarged and tumefied, completely blocked up the entrance to the pharynx. The posterior nares were so closed that it was only possible by supreme efforts to breathe through them, and then only after lumps of hardened mucus had been expelled anteriorly, or drawn back into the pharynx. On pressing the tip of the finger against the back of the pharynx, it received the impression of touching a sodden mass. The entrance to the œsophagus was wellnigh closed. Spasm of the glottis occasionally imminently jeopardized the life of the patient. From all these inflamed surfaces ropes of tenacious mucus were blown through the swollen structures and out of the mouth. This was at first, even, effected with extreme difficulty, on account of the impaired mobility of the muscular structures involved, and at length became impossible, so that the sponge-mop was called into requisition. He could use the last (fortunately) most effectually; for all sensation was abolished in the parts, and no gagging was induced by the operation. Free inhalations of steam charged with nitrate of silver aided greatly in detaching the mucus, and in some slight degree, too, in restoring the muscular contractility, by its astringent properties. Yet each inhalation was dreaded, because of an impending suffocation, induced by so free a liberation of the mucus. To crown all this suffering, agonizing pain would shoot up the back of the neck and head, which the patient compared to a blow received on the head from a sledge-hammer,—a symptom which I afterwards learned to regard as of diagnostic value. Perfect nervous prostration was a mere matter of time under such circumstances, and the tendency to it was hastened by the unlimited quantities of narcotics which the suffering man was goaded into taking.

When in the erect position, the hands were applied one to either side of the occipito-cervical region, to support and steady the head and to relieve its inflamed base of support.

Looking at the case now from the vantage-ground of the experience it afforded, the diagnosis seems to be clear enough. At the time, however, I was obliged to eliminate simple though universal

pharyngitis, the previous rheumatic attack, retro-pharyngeal abscess, any specific disorder, and erysipelas of the mucous surfaces, and to seek for a diagnosis in another direction.

Was there a breaking down of the bony structures? This seemed to be the most probable conclusion, reasoning both directly and by exclusion. There was no evidence of pus pointing in a visible location, external or internal, neither did it appear to be gravitating down along the spinal column. I was aware of the fact that pus forming amid the deeper structures of the neck would, for a long time, give no external indication of pointing, and that if it did form there, it would, as remarked by Brodie, probably give the most marked signs of its existence at the side of the neck; hence the temptation to make a free incision just below the mastoid process was at times very strong. The statement of Chelius, that there is not usually any external diseased indication in the neck (when its bones are diseased), except that the patient cannot bear the least pressure, served to confirm my diagnosis.

A number of facts led me eventually to conclude that, whatever the essential element might be that caused the disease, I now had to do with a case in which the reparative power alone was unequal to the emergency, and that, if I regarded the common-sense, time-honored aphorism, to 'counteract the tendency to death,' it must be by treatment of the most tonic and supporting character. I had fairly tried the antiphlogistics, the sorbefacients, and the alteratives in their many combinations, my patient, in the mean while, becoming no better. The question now was, could he do worse if I tried the opposite? Moreover, the original treatment was predicated on the idea that the disease was a genuine hyperplastic condition, rather than what a clearer diagnosis pronounced the exact reverse.

Treatment now became, rest in bed, with the head supported and buried in a bran pillow, which acted as a splint, and which, when warmed, served greatly to mitigate the pain; discontinuance of all narcotics as fast as the patient could break away from them; generous diet, and tonics,—ferri vin. amar., tr. nucis vom., and Fowler's solution in combination, alternated with cod-liver oil and iodide of iron,—and they were pushed to the full extent of the patient's tolerance. In a few days this change produced a decided improvement.

Notwithstanding the continuance of the pain, there was an actual increase of weight. Still the throat remained swollen, but had lost its puffy feel, and when the back of the pharynx was touched, there was gained by the finger the sensation of a solid infiltration of the structures. Had I been less firmly convinced than I was of the accuracy of my diagnosis, I should probably have continued the exhibition of the mercurials and iodides to induce absorption of this mass.

December 3.—I noticed two small protuberances on the back of the pharynx. They were similar to the fungoid mass one finds over the fistulous openings to carious bone elsewhere. They gave me the last link wanting to complete the chain of evidence. The diagnosis was correct, and I had to do with a case of vertebral caries. In addition to the supporting regimen, I now maintained pretty constantly a mild counter-irritation over the back of the neck.

December 12.—Two small pieces of bone escaped from the openings beneath the fungoid granulations in the posterior wall of the pharynx. One was secured, the other was lost. The cause of all this intense, long-continued suffering seemed ridiculously small when compared with the aggravated effects produced. The piece of bone secured was not more than one-sixteenth of an inch thick, and less than one-quarter of an inch square surface. The piece lost was, in all probability, even smaller. Certain resemblances made me regard the piece I had secured as being the small process in front of the atlas, which is the homologue of the body of the vertebræ lower in the spinal column. It is the portion called by anatomical writers the tubercle. An accomplished medical friend in Philadelphia quite succeeded in convincing me that the portion came from the axis, as it was more nearly on its level; and so I had concluded to think, until September 5, 1871, when, after a period of comparative quietness for nearly a year, the neck again began to swell and the pharynx to become tumefied. A new portion of dead bone now appeared, and was secured, after which the swelling in great part disappeared. The shape and character of this fragment made manifest to me at once that my previous conclusion was correct; for this piece could be no other than the polished surface of the atlas, against which the anterior portion of the odontoid process rubs. One conclusion confirmed the other. September 13, 1872, another small fragment was secured from an undecided location. Its extrusion gave rise apparently to little or no local or constitutional disturbance.

At present, the patient seems to enjoy fair health and to suffer but little from the disease, though I am not sure that he is exempt from a return of it, under any exciting cause.

There is some swelling in the back of the neck, some huskiness of voice depending on pharyngeal changes, and some stiffness of the neck, with an apparent want of confidence in making quick, free movements; but the pain has almost gone, and the patient may be considered as doing well. At present it may be best to hazard no opinion as to the permanency of the cure, as this depends on so many contingencies.

ATROPIA IN THE NIGHT-SWEATS OF PHTHISIS.

BY J. C. WILSON, M D.

DURING the winter of 1870-71, while Resident in the Pennsylvania Hospital, I made, at the suggestion of Dr. Da Costa, in whose ward I was serving, some observations upon the influence of atropia in controlling the night-sweats of advanced phthisis. I now, by permission of Professor Da Costa, present the cases to the profession, reluctantly it is true, because my opportunities for pursu-

ing the investigation have been limited, but in the hope that the suggestion may not be wholly without fruit, in here and there affording relief—even though it be but temporary—to this distressing phenomenon of consumption.

The first case is given somewhat in detail, because the atropia was not resorted to until numerous other remedies had been thoroughly tried and had failed.

Case I.—William N., bed 3; admitted to the ward November 1, 1870; æt. 21. Both parents died of phthisis. He is very tall and thin; weight 123 lbs. His health has never been good, but he dates his present sickness from last May, when his cough began. There are signs of tubercular deposit going into softening at left apex, and some deposit throughout the left lung; crackling and markedly prolonged expiration at right apex. He has never had spitting of blood. There is marked clubbing of fingers. Cough troublesome; expectoration puruloid; some soreness of fauces; no thoracic pain; hectic and night-sweats constant and distressing. Appetite fair; bowels constipated.

Treatment.—On admission he was ordered Niemeyer's pill t. d., a tonic of gentian and nux vomica, and for the sweats ten drops of aromatic sulphuric acid at night. Milk-punch.

November 21.—Condition much the same; he has lost flesh since admission; the sweating is not controlled. He complains greatly of the suffering this symptom occasions him. It is so profuse that he is compelled to change his underclothing twice in the night.

Stop Niemeyer's pill; double the dose of aromatic sulphuric acid; continue the tonic. Sponging at bedtime with *hot* water ordered, and ol. morrhuæ added to treatment.

December 2.—The sweating continues. Stop the acid, and give in place of it tannic acid gr. v at night. The oil does not suit him—stopped.

December 9.—Tannic acid has not relieved the sweating at all—stopped. To take oxide of zinc gr. ij, with extract of hyoscyamus gr. j, four times daily. Also compound syrup of the hypophosphites, f℥ij t. d.

December 18.—The sweats are unabated. The man is losing ground very rapidly. Stop zinc; give atropia in granules gr. $\frac{1}{60}$ t. d.

December 30.—*Since the last note he states that the sweating has considerably diminished.* Complains of dryness of fauces; pupils are not affected.

January 3, 1871.—Throat very dry. Atropia discontinued. To take tinct. opii deodorat. gtt. xxx at bedtime.

January 8.—*Has had profuse sweats every night since the atropia was stopped.* Atropia to be resumed.

January 11.—*He states that there has been only moderate sweating since last note.* Pupils slightly dilated; fauces dry.

Pneumothorax suddenly supervened from the rupture of a cavity, and the man died, January 12.

The case was reported, under the head of "Clinical Notes," in the number of this journal of February 15, 1871, without full notes of the treatment. Mention is, however, there made of the effect of atropia in controlling the sweats.

Case II.—Samuel V. R., admitted to the ward February 13, 1871; æt. 24. No family history of phthisis. His illness dates from a severe cold, taken in November, 1870. Has never had spitting of blood. His cough was at first attended with a whitish expectoration, which gradually changed in character. It is now slightly purulent. The man presents the rational signs of progressing pulmonary consumption. The physical signs are, however, not proportionately marked. There is flattening of the chest anteriorly on both sides, with diminished expansion. There is prolongation of the expiratory murmur at right apex, with increase of vocal fremitus under the right clavicle, and relative dulness on percussion to lower margin of the second rib anteriorly, and to the middle of the scapula posteriorly. The harshness of the breathing extends to angle of the scapula. There is no crackling; occasional mucous râles in right side. The nails are incurvated and the fingers clubbed, more markedly on the left side. Appetite poor. During the last week he has had hectic and moderate night-sweats.

Treatment.—A pill containing iron, quinine, and digitalis; good food; milk.

February 23.—The sweating has occurred every night since his admission to the ward, and is more profuse. Ordered atropia gr. $\frac{1}{60}$, morning and evening; a small amount of stimulus to be added to his treatment.

February 24.—Sweating not affected; pupils not dilated; states that his throat is dry, but that this is habitual.

February 25.—*Last night there was very slight sweating, which was confined to the hands and face.* Pupils somewhat affected—he cannot read. Throat no dryer than usual.

February 28.—Since last note the sweating has been very slight; it does not disturb him. He thinks the granule at night makes him sleep better. The pupils are less dilated than at last note; can read with some effort. Throat no dryer than before he began atropia.

Case III.—Edward H., admitted January 13, 1870; æt. 20. Family history shows no tendency to consumption; parents both living, and eight brothers and sisters alive and well. His own health, he states, was very good until November, 1870.

The trouble commenced as a naso-pulmonary catarrh. Has never had hæmoptysis. Has lost flesh greatly; has cough with muco-purulent expectoration; appetite poor,—occasionally vomits after eating; bowels regular. There is a slight irregular hectic paroxysm, and profuse, drenching sweats at night. Fingers show markedly the Hippocratic deformity.

Signs of consolidation at both apices, most marked at right, where softening is already taking place.

Ordered, on admission, a pill of quinine, digitalis, and extract of opium, with external use of iodine; subsequently the treatment was changed to cod-liver oil and syr. ferri iodidi, with morphiæ sulph. at night.

February 13.—The case progresses; softening evidently taking place in upper part of left lung. The cough at night is alleviated by morphia. The night-sweats, which for a time were less troublesome, are again profuse; they occur almost every night, and he states that they are worse when his sleep is sound. Ordered atropiæ sulph. gr. $\frac{1}{60}$ in granule, morning and evening.

February 14.—His sweating was less profuse; complains of dryness of throat; pupils slightly dilated.

February 15.—Last night slept well; merely a little sweating of face and hands. Throat very dry; pupils moderately dilated; accommodation affected; can read only a few words at a time.

February 22.—Has had no sweating at night since last note. Complains of diarrhœa; has had for past two days five or six movements in the twenty-four hours; syr. ferri iodidi and atropiæ sulph. discontinued. Pupils moderately dilated; throat dry; complains of constant thirst; this symptom existed to a slight extent prior to the use of the atropia. Ordered subnitrate of bismuth in five-grain doses every four hours.

February 24.—Diarrhœa has ceased; has no thirst; pupils nearly normal; reads without difficulty. *Had a drenching sweat last night.* Atropia resumed in same dose.

February 28.—*States that he has had no sweating*

since last note, except a moderate perspiration on waking this morning. Pupils normal; accommodation unaffected; no unusual dryness of throat, nor thirst, for past two days.

Case IV.—Michael B., admitted to the ward February 21, 1871; æt 28. His father died of consumption at the age of forty-nine. His sickness began about five months ago with spitting of blood. There are signs of extensive deposit in the left lung, with gurgling at the left apex. Cough troublesome; considerable muco-purulent expectoration; slight clubbing of fingers. Has lost flesh greatly. During the last six weeks has had night-sweats; they are now profuse, drenching.

Treatment.—On admission, he was ordered ol. morrhuæ, and a cough mixture consisting of aromatic sulphuric acid and deodorized tincture of opium in syrup of wild cherry and elixir of cinchona; stimulus.

February 23.—To take atropia, gr. $\frac{1}{60}$, morning and evening.

February 24.—Complains of dryness of fauces; pupils not dilated; the sweating last night, after one granule, not lessened.

February 25.—His sweating was, he states, less profuse last night.

February 27.—The sweats were rather slighter during the last two nights.

February 28.—Last night the sweating was very severe. His bowels, previously constipated, are now moved twice daily; pupils moderately dilated; great dryness of throat.

Case V.—A colored man, named Greaves, who had suffered from prostrating night-sweats for months. He was relieved after taking the granules twice daily, for a short time, and for two or three nights while I had him under observation had merely moderate perspiration. In this case the atropia caused dizziness and diarrhœa. It is to be regretted that the notes have been mislaid, and I possess at this time merely a brief memorandum of this case.

Dr. Ellwood Wilson, to whom these observations were made known, has used the granules of atropia in the sweating of advanced phthisis in private practice, with very satisfactory results; the sweats being greatly controlled, although they were in no case under his observation stopped entirely. He also employed atropia successfully in the case of a lady, an opium-eater, suffering from extreme debility attended with profuse, colliquative night-sweats. The relief from this distressing symptom was speedy, and very grateful.

Quite lately, also, Sidney Ringer, in *The Practitioner* for August, 1872, has called attention to the influence of belladonna in checking certain anomalous cases of habitual sweating. He gives cases of unilateral and local sweating, and of sweating in children, which were some of them cured, some decidedly alleviated, by the external use of this drug in the form of the liniment and the ointment. He also injected $\frac{1}{100}$ gr. of atropia hypodermically in several cases, with the effect of speedily stopping the sweating. In a case of unilateral sweating of the right side of the face, this treatment caused the sweating to cease entirely in about a minute; and it did not recur during three-quarters of an hour that the patient remained under observation. A woman suffering from acute rheumatism was subjected to the hot-air bath, and subsequently to cold sponging, which caused very free sweating for several hours; $\frac{1}{100}$ gr. of atropia terminated this sweating in about a minute, but it recurred in about two hours. A man, a boy, and the resident assistant of the ward, Mr. Johnson, were then subjected to the hot-air bath, and in two cases, in about a minute—in the case of the boy, almost immediately—the subcutaneous insertion of $\frac{1}{100}$ gr. atropia caused the violent sweating thus induced to cease, and in none of these cases did it return. Mr. Johnson stated that his skin seemed so dry that "he felt as if he should never sweat again."

TRANSLATIONS.

A FEW REMARKS UPON THE RELATION OF HÆMOPTYSIS TO PULMONARY CONSUMPTION.

Translated for the *Philadelphia Medical Times* from the German of Professor Felix von Niemeyer.

BY HAMILTON OSGOOD, M.D.

(Concluded.)

EPISTAXIS is almost never attended with danger. This cannot be said of bronchial bleeding; for here it easily happens that the *whole* of the blood which is poured into the bronchia is not coughed out, but oftener that a portion of the same flows down into, or is rather inspired into, the alveoli, and there works as an inflammatory irritant. Many cases of pneumonia which thus arise terminate in delitescence; other cases end in condensation and contraction of the affected lung-tissue; in still other cases, not by any means rare, the inflamed infiltrated section of the lung and the deposit of blood which it contains pass into a cheesy metamorphosis, and thus out of the hemorrhage is developed a *phthisis florida.*

Against the correctness of this theory, Traube has objected that, at the autopsies of such of his patients as have died during the progress of an hæmoptysis, with the exception of those cases in which death during hemorrhage has been the result of suffocation, he *has never found coagula in the bronchia.* I have already mentioned that the autopsy of the young Swiss theologian, in whose case the hæmoptysis continued until his death, showed bronchia perfectly free from blood-clots. In the preceding autumn, Professor Schüppel, at my request, made the post-mortem examination of a young merchant in Reutlingen, in whose case a pneumonic infiltration of the lower lobe of the left lung became developed eight days after a severe attack of hemorrhage. The attending physician had not only repeatedly seen the patient during the course of these eight days, and convinced himself that the young man attended to his business without discomfort, but he had also, later, followed with precision the appearance, the extension, and the lingering course of the pneumonic process. When I visited the patient, in the sixth week of his illness and several days before his death, it was almost impossible to count his pulse; the skin, covered with sweat and miliaria rubra, was burning hot, the sensorium benumbed. In the entire compass of the lower lobe of the left lung the percussion-note was absolutely dull, and one heard, in the region of the dulness, loud bronchial respiration and sonorous râles. At the autopsy it was found that the whole of the left pulmonary lobe had undergone cheesy infiltration. Besides this was also found, but in the right lung, a cheesy nodule of the size of an apple, sharply bounded and of beautifully wedge-formed shape, which presented the most striking resemblance to a hemorrhagic infarctus in the

process of cheesy metamorphosis. *In the bronchia there was not the slightest trace of coagula.*

I must, therefore, through my own experience, corroborate Traube's remark, that blood-clots are only exceptionally found in the *bronchia* of individuals who die during, or a short time after, an attack of hæmoptysis. But I do not comprehend in what manner this circumstance invalidates the accuracy of my opinion touching the connection between hæmoptysis and pulmonary consumption, not to mention the refutation of the same. I have not asserted that the blood which is poured into the *bronchia*, but that which flows into—that is to say, has been inspired into—the *alveoli*, if it be not expectorated, is what acts as an inflammatory irritant, and, in numerous cases, lays the foundation of lung-phthisis. It is well known that blood is much more easily removed from the bronchia, especially from the larger tubes, by coughing, than from the alveoli. It is even not improbable that only in the larger bronchia does the presence of blood excite cough and cause expectoration. Almost all patients who have suffered from hæmoptysis declare that "a warm sensation rises up under the sternum, and then, without exertion, by a light cough, a liquid, frothy blood is expectorated."

It has been here and there firmly asserted, upon theoretical grounds, that blood from the bronchia cannot flow down into the alveoli; but, according to the affirmations of all reliable pathological anatomists, the autopsies upon individuals who have died during the progress of hæmoptysis constantly reveal localities in the lungs, of greater or less extent, in which the alveoli are filled with blood. Förster remarked, after describing the dark and clear spots in the lungs, which indicate the districts, into the alveoli of which blood had sunken, "The metamorphosis of blood which has flowed into the air-cells of the lungs, causing the spots already mentioned, has not yet been more accurately followed; the examination of the sputa, however, during the days which follow the bronchial hemorrhage, shows that the blood is gradually expectorated along with a mixture of mucus and pus." I do not consider it as at all unlikely that in hæmoptysis the capillaries of the alveoli take part in the hemorrhage; perhaps, indeed, they form the principal source of the bleeding. Many authors assert that every abundant hæmoptysis originates in the erosion or rupture of those smaller branches of the pulmonary arteries which exist in the walls of cavities. The ground which I have taken against this assertion does not deny that the source of the blood is the capillaries of the pulmonary arteries. That the conditions for the occurrence of a capillary hemorrhage in the alveoli of the lungs are particularly favorable, requires no especial mention.

Traube has also failed to refute the statement that in hæmoptysis, not at all rarely, blood finds its way into the alveoli of the lungs and there remains. I must, therefore, hold fast to the opinion that certain cases of pulmonary consumption originate in this way, and that the blood which remains in the alveoli, as well as the products of the pneumonic process which is called forth by the same, undergoes cheesy metamorphosis.

The accuracy of the generally received statement that in the beginning of an hæmoptysis, with extremely rare exceptions (to which precisely the case reported by Traube belongs), neither appearances of fever, nor pain, nor other signs of inflammatory disease of the lungs exist, has not been denied by Traube. He believes that a slight increase of the body-temperature is frequently overlooked, but he admits (what I have repeatedly confirmed through exact measurements of the temperature of the body) that cases also occur in which, at first, every sign of fever fails.

But, far from inferring from this fact that, as a rule, the hemorrhage is the primary and the pneumonic process the secondary lesion,—a conclusion to which all medical authorities must be led, if only they can, without constraint or prejudice, follow the origin and course of phthisis,—Traube gives it another meaning: "Since bleeding belongs to the most effective anti-febrile remedies, there is no importance to be placed upon the slowness of the pulse in the beginning of many cases of hæmoptysis. Under the influence of the hemorrhage, the temperature can by no means exceed the normal limits, except in a trifling degree, and the pulse-frequency not at all. The case which, in truth, at first is feverless, may be thus made clear: In the beginning, the inflammation is confined to a few circumscribed localities, and acts as a febrile irritant only when it has extended itself over greater spaces."

To the judgment of my colleagues I leave the question as to whether they believe that this view or my own approaches the truth most nearly, and will restrict myself to a few points, which, in respect to the correctness of my view, seem to me of considerable weight.

First, I turn back once more to the familiar fact that in the case of many persons the onset of hæmoptysis is preceded by repeated attacks of epistaxis. Nobody thinks of attributing this epistaxis to a tubercular condition, nor to a peculiar form of inflammation of the nasal mucous membrane. If now, in one and the same person, this simple capillary hemorrhage of a mucous membrane, very rich in blood-vessels, is followed by a capillary hemorrhage of another likewise very vascular mucous membrane, and if in both cases, in addition to the symptoms of the bleeding, no other morbid indications are to be discovered, I dare to assert that no special significance is to be inferred from one hemorrhage more than from the other.

I would further call to mind the certainly indisputable fact, that it is not by any means rare for an abundant hæmoptysis, which continues for days in succession, giving rise to great solicitude on the part of both physician and patient, to finally cease without leaving behind it a single other trace than an exhaustion, which soon disappears. Since I have learned Traube's views only from the report of his assistant, I do not know whether, in such a course of hæmoptysis, he infers *its* rise also from a tubercular pneumonia which remains either latent or becomes retrogressive. For myself, there exists no doubt that in those cases in which individuals, after single or repeated attacks of hemorrhage, remain free from phthisis, and reach a great old age, it is to be understood that following the attacks of hæmoptysis no blood remains in the alveoli, but that, in the manner which Förster describes, it has been expectorated. The accuracy of this explanation is especially supported by those cases in which a first and second attack of hæmoptysis pass harmlessly by, while a later one, which differs in no wise from the preceding, is at once followed by the signs of a commencing phthisis of the lungs. Since I emancipated myself from the prejudicial effect of the doctrines of Laennec, exact observations as to the appearance or non-appearance of fever and symptoms of pneumonia, in the days next following the beginning of an hæmoptysis, have won, for myself and my pupils, the greatest prognostic value.

Finally, the known fact that pulmonary consumption frequently follows traumatic hemorrhage of the lungs, appears to me to be another support of my opinion. In the days when, in the various universities, duels with thrusting weapons were customary, even the laity knew that a so-called "lung-thrust" was less dangerous in its temporary effect than in the evil consequences which followed after a lapse of time, more or less long. By many writers (Piorry), the frequency with which penetrating chest-wounds, leading to hæmoptysis, are followed by phthisis has been overstated; but some truth lies beneath the statements. To my regret, I have not succeeded in obtaining possession of

a single one of the dissertations which appeared several years ago, in which, as I am told, attention was called to the danger to which operations in the throat give rise; which danger consists in the downward flow of blood into the lungs and in the retention of the same in the alveoli. I am, indeed, convinced that without these observations, the ancient doctrine, according to which certain cases of pulmonary consumption are called forth by an hæmoptysis, would have broken a new path, or, more strictly speaking, after a comparatively short intermission, during which it would have been doubted upon theoretical grounds, this doctrine would have found a new and universal recognition. But it has not escaped my notice that this universal recognition has been deferred and rendered difficult by the opinions which Traube has raised against the part of my clinical lectures now in question.

The correct belief that a neglected catarrh is attended with a secretion rich in cells, through which secretion the lesion extends itself into the alveoli, and that the product of the catarrhal pneumonia thus arising degenerates into a cheesy metamorphosis, has already found such a widespread acceptation, and has struck its roots so deeply, that it begins to exercise upon the careful treatment of catarrh and upon the prophylaxis of phthisis a most happy influence. In like manner, the majority of physicians now already share the opinion that every form of pneumonia, when the inflammatory infiltration does not of itself disappear, but runs into cheesy metamorphosis, can lead to consumption; which view stands in direct opposition to the doctrines of Laennec. Properly speaking, only *one* of the propositions already quoted from the theory of Laennec—viz., that consumption of the lungs can never develop itself from a bronchial hemorrhage—is, in distant circles, still accepted. This opinion, however, stands upon as weak a footing as the two remaining assertions,—that pulmonary consumption never follows a neglected catarrh, and that it can never originate in an acute or chronic pneumonia.

In spite of what I believe to be my perfect refutation of these opinions, I still miss a decided and general assent to my satisfactorily grounded assertion, that among the pneumonic processes which, through the cheesy metamorphosis of the products of inflammation, lead to consumption, those processes which arise from the retention of blood in the alveoli, after an hæmoptysis, have also a rôle to play. The lack of, or at least the lukewarm, assent to my opinion does not surprise me, because the objections against the correctness of the same originate with a man whose undisputed authority in the pathology and therapeutics of the organs of respiration must carry with them a great weight.

The respect which I entertain for Traube's scientific accomplishments has caused me to defer the refutation of his objections until I had, through continued observation of new cases of disease, exposed the same to the most searching proof.

Finally, in order to protect myself from misconception, I once more briefly define my views concerning the relation of capillary bronchial and pulmonary hemorrhage to consumption of the lungs, in the following propositions:

1. By no means all individuals who suffer from capillary bronchial and pulmonary hemorrhage are, or become, consumptive.

2. Not unfrequently, consumption of the lungs follows capillary hemorrhage of the lungs and bronchia, without the existence of a genetic connection between the hemorrhage and the pneumonic processes which, as a rule, form the origin of the phthisis. The same individuals who are predisposed to these hemorrhages are also disposed to the inflammatory processes just mentioned.

3. Capillary bronchial and pulmonary hemorrhages frequently lay the foundation of phthisis in persons in whose lungs neither tubercle nor pneumonic products exist; and the reason for this is, that the blood which is retained in the alveoli of the lungs, and the inflammatory products which are called forth by the same, undergo cheesy metamorphosis.

4. In the same manner, bronchial and pulmonary hemorrhages not rarely hasten the course of an already existing phthisis.

5. In individual and rare cases, hæmoptysis is not the cause, but the *consequence*, of pneumonic processes, which in their protracted course lead to pulmonary consumption. Such cases are easy of recognition, because commonly severe fever and other indications of inflammation accompany or precede the hæmoptysis.

6. The blood which remains in the alveoli, and which, together with the pneumonic infiltration, has become cheesy, sometimes causes an eruption of miliary tubercle.

[The above monograph was written by Niemeyer about fifteen months previous to his death.—TRANS.]

NOTES OF HOSPITAL PRACTICE.

JEFFERSON MEDICAL COLLEGE.

CLINIC OF PROFESSOR S. D. GROSS, M.D.

Reported by FRANK WOODBURY.

TUMOR IN MAMMARY GLAND.

AN apparently healthy, married lady of fifty-three years, appeared at this clinic on the 14th of last month, on account of a painful tumor of the right breast, which she had first noticed only two months before, since which time it had increased considerably in size, and occasioned her much anxiety. She could not bear the pressure of a tight dress upon it, as this increased the pain.

The lecturer proceeded to examine the patient. We find a circumscribed, movable tumor, rather deep-seated, and external to the nipple. It is nodulated, but not uniformly hard; in places it appears softer, as if it contained small cysts with fluid contents. Although appearing of considerable bulk, yet when the surrounding adipose and cellular tissue are dissected off, it will be of rather small size. The breast is freely movable; soft, except in the affected spot, and the nipple is natural and not retracted; the skin being healthy and not adherent or attached to the tumor. The pain is sharp and neuralgic in character, and the patient thinks it is worse in wet weather. This tumor strongly resembles a gland undergoing fibroid degeneration, but I cannot state more positively in regard to it, until I can make a section of it before you, on a plate. There are no enlarged glands in the neighborhood of the tumor, or in the axilla.

This is not cancer. You might expect to find a scirrhus of the breast in a woman of this age, as it generally comes on soon after the decline of the menses. In scirrhus the tumor adheres to the surrounding structures, so that by the time it attains this size it is not freely movable, as this one is. The skin also would be discolored and brawn-like, and the nipple retracted early in the disease, forming a prominent diagnostic symptom. The glands of the axilla in scirrhous disease become involved, and the morbid structure soon breaks down and forms one or more irregular, foul-looking ulcers, with hard depressed edges, discharging a sanious, offensive, acrid fluid. The affection before us does not resemble encephaloid disease, which is comparatively rare in the mammary gland; nor is it like epithelioma, colloid, or melanosis, which also are extremely

uncommon in this situation. Adenoma and fibroma frequently occur here, but are mostly met with in young girls shortly after puberty, in whom generally co-exist, and may be connected with, dysmenorrhœal troubles and a nervous temperament. It also occurs, occasionally, soon after marriage and during the first pregnancy. We might use in its treatment the cicuta plaster or the opium plaster, as palliatives; or sorbefacient applications; but the only effectual remedy is the knife.

Chloroform was administered and the tumor removed; part of it was hard, dense and resisting to the knife, white in color, and resembled a degenerated lymphatic gland. Throughout the greater part of its bulk it contained a number of cysts of varying sizes, in which was a dark-colored, jelly-like fluid.

September 21, the patient was again presented. A slight erysipelas had supervened upon the operation, but had yielded promptly to remedies. This erysipelas may have been produced by a number of causes, which we will not recount, as it could at best be nothing but conjecture. A tendency to erysipelas seems to exist in some persons, particularly those of a nervous, irritable temperament: it is also seen in intemperates. This affection prevails more at some seasons of the year than others, and is sometimes endemic in certain localities. Some peculiarity of the atmosphere, which sometimes exists in hospitals, seems to exert a powerful effect, both in predisposing patients to the disease and producing an attack. Simple erysipelas exhibits itself as a bright red discoloration of the skin, which has a marked tendency to spread. In its treatment we may use equal parts of tincture of iodine and alcohol, which may be painted on with a brush twice or thrice daily; or a cloth may be kept on the part wet with a solution of muriate of ammonia, acetate of lead, and opium, or even cold water. In the phlegmonous variety, and in that form supervening upon a wound or ulcer, which involve structure beneath the epidermis, the treatment by vesication is particularly beneficial.

The tumor was carefully examined by Dr. R. M. Bertolet, who made the following report:

"The mammary tumor, which is made up of a number of small cysts filled with a dark, straw-colored, gelatinous fluid, is a *cysto-sarcoma mucosum*. The microscopical appearances are briefly as follows:

"The dilated lacteal ducts and the attenuated and distorted glandular acini form the round cystic spaces. These are filled with a fluid of a semi-solid consistence resembling the jelly of Wharton, and composed of a meshwork of anastomosing stellate cells, with a hyaline intercellular substance which is rendered cloudy upon the addition of acetic acid. The remains of the original lining of cylinder epithelium are, now and then, seen upon the walls of the cysts. From the walls of the glands are seen springing many papilla-like proliferations, also generally deprived of their epithelial covering.

"Throughout the growth are imbedded numerous sarcomatous cells of the small-celled variety."

We can assure this patient that the disease, in all probability, will not return; as circumscribed sarcoma (including the fibroid and cystic varieties) is the least malignant of all its forms.

STRUMOUS HYPERTROPHY OF THE LIP.

This case, a boy ten years old, exhibited a peculiar development of the upper lip, which was thickened and pendulous. This condition had existed for three years; otherwise he enjoyed good health.

This is a curious affection, but it is one that is occasionally met with in young persons with the strumous diathesis. It occurs almost exclusively in the upper lip and in the young of both sexes. In these cases the lip has twice its natural thickness, is hard and rigid, and sometimes shows a tendency to ulcerate. The affection is frequently accompanied by strumous manifestations in other portions of the system, such as enlarged tonsils and psorophthalmia. The firmness and induration of the lip, the absence of co-existing disease in the gums and teeth, and the chronic nature of the enlargement, together with the scrofulous appearance and condition of the patient, will generally make the diagnosis sufficiently clear. No operation is needed for its relief. Attention to the secretions, with some alterative medicine, or a mild course of mercury when other means fail, will generally be all the treatment required.

The patient has a broad nose, and his face has a heavy expression, as if his mental operations were slow. He states that there is no disease in the family, of which he is aware, and his parents are healthy people. His tongue is a little coated, but not more so than the American tongue generally is, because everybody eats too much in this country. We find no enlarged glands along the sterno-cleido-mastoid or under the angle of the jaw, which so frequently exist in scrofulous subjects. If they were here, however, we should not bring that fact forward as conclusive proof that this, or any disease here, was scrofulous, as they might be enlarged independent of any disease. But from other sources we derive the evidence that this is an enlargement of the lip of strumous origin. We may distinguish two kinds of scrofulous subjects. The first variety are blondes, with blue eyes, and a light florid complexion, with a vigorous circulation and a bright precocious mind. In these the disease manifests itself in the bones, joints, skin, and lymphatic glands, and they are not so liable to suffer from consumption as the second class, who are generally dark, with a pale and unhealthy complexion, tumid lip, and drooping eyelashes; they are dull and languishing, and show no activity of brain or muscle. When I was in Louisville I attended a young lady of nineteen years, who was a blonde with very light hair. Though in other respects healthy, her upper lip was immensely enlarged and indurated to the touch, more so than in the present case. In the case referred to, I derived great benefit from the officinal solution of baryta. This is a powerful detergent and alterative, and is especially adapted to strumous cases where there is a deficiency of blood and the face and lips are pallid; this is not exactly the case here, but it will make a decided improvement in the boy's appearance, in a short time.

℞ Liquor. barytæ, gtt. iv,
Tinct. ferri chlorid., gtt. x. M.

S. To be taken in a tablespoonful of water, morning, after dinner, and at bedtime.

We will make no change in his diet; he may take his accustomed food, taking care, however, that he has outdoor exercise, and that his bowels are kept in a soluble condition. We will see him from time to time, and note his progress.

EPITHELIAL DISEASE GRAFTED ON A CONGENITAL WART.

This man, a blacksmith by trade, was forty-eight years of age, and came from Frenchtown, N. J.

The patient states that from his birth he has had a wart or mole in the right groin, immediately above the centre of Poupart's ligament. This remained in a stationary condition until one year ago, when, during a fit of sickness, he thinks he accidentally scratched its top off, with his finger-nails. Since that time it has gradually enlarged, and finally ulcerated, producing an offensive discharge. The tumor is now as large as a pigeon's egg, projects from the groin, and has a smaller, similar tumor on each side of it. He says that his general health is good.

This is a wart, which has taken on epithelial disease.

The accident he mentions may have induced it, but probably had but little connection, if any, with the origin or development of the morbid action. The tumor is covered with cacoplastic lymph, it is tuberculated, and distantly resembles a large mulberry. It is hard and incompressible, and discharges a scanty, fetid pus, slightly bloody, probably due to the friction of the patient's clothes upon the tumor. The lymphatic glands of the groin are enlarged and indurated from the anterior superior spine of the ilium to the pubic bone, and in all probability this condition of the glands likewise extends into the interior of the pelvis and abdomen. This fact very much complicates the case, and it is doubtful if the most careful and skilful surgeon could operate so as to remove the tumor and all the enlarged glands. In fact, this would involve such a serious operation that I refuse to operate, because it would fail in its result unless all the diseased glands were removed; and even after they were, the disease, being malignant, would be almost certain to return either in the cicatrix or elsewhere in the body, and so perhaps hasten the fatal result. This case is interesting, as it shows how a wart may remain dormant for nearly half a century, and finally take on malignant action; it might have been encephaloid or scirrhus, just as well as epithelioma.

We will direct the patient to wash the part frequently with a dilute solution of permanganate of potassa, which is a powerful deodorizer. It is not worth while to give any remedies internally. In spite of the praises of some practitioners in favor of arsenic, who consider it as having almost a specific virtue in this disease, I have not only utterly failed to find it of any special value in treating this affection, but in my experience I have not seen it produce the slightest effect upon the disease, beyond improving the general health, as a tonic.

Until we have more light than we now possess on the nature and treatment of these carcinomatous diseases, our only reliance will be upon prompt and complete extirpation of the diseased structures.

PHILADELPHIA (BLOCKLEY) HOSPITAL.

SURGICAL CLINIC OF F. F. MAURY, M D.

Reported by FRANK WOODBURY.

ON Wednesday, September 4, a large number of students were present to commence the regular winter course of clinics at this institution. The first case introduced was one of

EPITHELIAL CANCER OF THE LIP.

This existed in a man, about 45 years of age, who had been admitted to the hospital a few days previously on account of a small dense tumor, irregular in outline, which protruded from his upper lip. Oval in shape, its base measured about one inch in its perpendicular, and three-quarters of an inch in its horizontal diameter. It projected about half an inch above the surface of the lip, on a line with the sesamoid cartilage of the nose and three-quarters of an inch from it. Extending along its lower edge there was a crack or fissure, filled with a dark-colored exudation. The patient stated that this began two years before, as a common wart. This was picked and irritated until it became sore, and finally ulcerated. Finding that it showed no disposition to heal, he went to a "cancer-doctor," who gave him a plaster to use, which made it painful, and it rapidly assumed the appearance now exhibited.

The lecturer said that, in connection with the subject of cutaneous affections, he brought this man before the class to show a curious lesion as well as to illustrate a peculiar pathological condition. On looking at the affection, you would at once pronounce this a disease of the epidermis, the outer layer of the skin, and due to a morbid action going on in the rete mucosum. This tumor consists of nothing but epithelial scales, such as rub off from any part of the body; but here there is inordinate generation of them, due to the disease, combined with a morbid secretion which glues them together. This is the composition and mode of formation of those horny tumors, which sometimes grow from a man's forehead and other situations, which are described in surgical works. But they rarely assume such large proportions; more frequently they are accidentally knocked off, or perhaps scraped off during sleep, leaving an open sore. This ulcer exists and is maintained by the epithelial degeneration.

The cause of this disease is uncertain. There seems, in some cases, ground for the belief that it may be hereditary. Dermatologists state that a tendency to epithelial disease exists in some persons, whether from effects of drinking or other causes, whose faces show the marked evidence of seborrhœa; this is followed by closure of the ducts of some of the sebaceous glands, whose accumulated secretion protrudes the skin in a multitude of points. Any of these may be irritated by picking, and a sore result, which may take on this peculiar morbid action.

This is not a syphilitic affection; it does not look like one. The patient has never had the disease, and if he had, this bears no resemblance whatever to the manifestations of syphilis.

This is known as cancroid, epithelioma, or epithelial cancer. It is called cancroid (cancer-like) because it resembles cancer in its general characters, except in the repullulating tendency or liability to return. Scirrhus, encephaloid, and a few other tumors, are almost certain to return after removal, from which they derive their title of malignant diseases.

The treatment of this is perfectly simple, and, if properly conducted, generally successful. The indication for treatment is to restore the natural healthy action of the part. The plaster this man had applied was probably highly irritating, and aggravated the morbid condition. Now, this is just what must be avoided. This disease already is caused and kept up by irritation, which must be reduced to invite healthy action. Never apply a local irritant that can only increase the trouble.

First, carefully remove the excrescence, which is really a large scab, and an ulcer is discovered underneath. Having shaved the hair from the vicinity, a piece of lint is wrapped around a stick of caustic potassa (as by this means it is held better than in the forceps), which is then carefully applied around the edges of the sore and thoroughly over its surface. Dilute acetic acid is then well applied, so as to neutralize the excess of alkali and prevent the extension of its caustic action. By this means an eschar is established and a healthy granulating sore substituted. After this, a poultice is to be applied for twenty-four hours. Then an appropriate dressing would be:

℞ Ung. hydrargyri nitrat., gr. xx;
Rhei pulv., gr. x;
Adipis benzoat., ʒiv.
M.

Apply several times daily, on a piece of patent lint.

No internal treatment is needed; in a short time he will doubtless be much improved.

CASE OF URETHRAL STRICTURE.

This man, 56 years of age, complained of difficulty in micturition. Sixteen years before, he had an attack of gonorrhœa, twelve years subsequent to which he had another attack. About fourteen months after his second attack he first noticed a trouble in urinating.

On attempting to introduce a sound, Dr. Maury found that a bridle stricture existed at the meatus, which so constricted the orifice as to only admit a probe. A tenotome was carefully inserted and the stricture divided, after which a small sound passed readily into the bladder.

The lecturer remarked that the mere fact of the passage of a small instrument into the bladder was not satisfactory evidence that no stricture existed. There might be a submucous constriction in progress, which would not be discoverable by a small sound, but which would afterwards develop. After successfully passing two larger sounds, the patient was told that, after rest in bed for a few days, he might go home relieved of the difficulty that had troubled him for so many years.

CONDYLOMATA.

This patient, about 40 years old, exhibited in the region of the perineum and anus, a number of flat broad excrescences, which secreted a serous fluid of a peculiarly fetid odor. At the other end of the alimentary canal a somewhat similar state of affairs existed. He showed a number of mucous patches on his lips and inside his mouth. He asserts, positively, that he never had syphilis, chancre, sore on the penis, or bubo, and said he was certain of it, because if he had he would have come immediately to the hospital. He acknowledged kissing loose women.

The lecturer considered that this was sufficient explanation; that osculation, where one of the parties had a mucous patch on the lip, was sufficient to inoculate the other. He was not certain that the saliva mingled with the highly contagious secretion from a mucous patch, was not able to convey the disease quite as readily as the matter from a chancre. This affection is a manifestation of constitutional syphilis. It is known as plaque muqueuse, syphilitic wart, or true condylome. There are several kinds of condylomata described by the writers, but this one is the genuine contaminating condylome, an outgrowth of syphilis, and comes on at a regular period from the onset of the disease.

As this is the manifestation of a constitutional disease, you must depend largely on internal remedies. For a local application several articles are recommended. A very good one is composed of equal parts of powdered alum and savine; this dries them up in a few days. Ricord uses calomel and arrowroot, which is quite as good. The application I am in the habit of using is chromic acid, full strength, which is nearly painless, and is, perhaps, more effectual than the others. This is applied with a pine stick, which is sharpened to an edge so as to introduce the acid into the sulci between the excrescences, being careful to protect the adjacent parts. This application may be repeated in a few days. To-night a poultice may be applied. The parts can be dusted several times a day with,—

℞ Hydrarg. chlorid. mitis;
Bismuth. subnitrat., aa, q. s. M.

The sores in the mouth will be touched with the solid nitrate of silver. He is taking the usual constitutional treatment.

Post-Partum Exploits.—At a recent meeting of the Obstetrical Society of Edinburgh, Dr. Keiller observed that he had recently witnessed several instances of extraordinary exploits on the part of women immediately after their confinement, without subsequent suffering. As showing what some women can do without any bad consequences, he stated that the other day a woman was delivered in the Old Assembly Close, no one being with her at the time. After the placenta came away, she put her room in order, and then, placing the child and the placenta in a basket, she walked coolly to the Maternity Hospital, within an hour after her confinement, to see if everything was right with her. Dr. Keiller exhibited the fœtus, which was apparently about the seventh month.

In connection with this case, Dr. Woodman, of Exeter, in the *British Medical Journal* of August 31, says:

"A young woman, a small farmer's daughter, came into Exeter by one of the branch lines, to see some friends off to London, and also, I suspect, to make arrangements for her confinement, unknown to her parents. Just as her friends were leaving, she felt rather poorly, and went upon Northernhay, and thence to the Castle Yard, where she was confined between ten and eleven A.M., on a seat in a retired part. No one was near, and she appears to have been unconscious for about an hour; when she recovered, she tied the umbilical cord with a piece of tape she had in her pocket, and leaving it behind, took off her jacket, wrapped the child in that, and started off to try to get lodgings. Not having brought much money with her, she was unsuccessful; and, although she managed to get some food, no one would take her in; she therefore, about nine P.M., went to the Guildhall, and the police at once sent her in a cab to the workhouse, where she arrived a little before ten P.M., and was at once placed in the Lying-in Ward and properly attended to.

"Although this woman had walked about, for nine or ten hours, without any attention to herself or child, no bad consequences ensued except bad colds to both."

Dugong Oil.—Attention (*Brit. Med. Journal*) has been recalled, by the contents of the Queensland Annexe at the International Exhibition, to the medical uses of dugong oil. It has been declared by more than one medical practitioner, following Dr. Holt, of Brisbane, to possess all the nutritive properties of cod-liver oil, and to be equally useful in all the forms of tuberculous and wasting diseases which are benefited by the administration of cod-oil; it is alleged to possess an actually agreeable flavor, to be pleasant as an article of food, and to be acceptable to those whose stomachs reject cod-oil. At a recent dinner in the Annexe, the pastry was made with dugong-oil, and was pronounced to be excellent.

Six Children at One Birth.—The first authentic case we (*Nashville Journal*) have ever heard of was reported last April, at the annual meeting of the Georgia State Medical Association, if we except the one recorded in the "Remarkable Cases in Surgery," 1857; but they all died in the evening of the day of their birth. Dr. George N. Holmes reported that, twenty-eight years ago, in Kentucky, he delivered a poor white woman of six babes at one birth. The children were perfectly formed, and weighed each two and a half to three and a half pounds. The parents were originally from Maryland. They afterwards moved to Arkansas, and he had heard that two of the children had died.

Glycogen.—M. Claude Bernard announces that he has recommenced his studies on the evolution of glycogen in the eggs of birds. He recalls to mind that in 1848 he discovered sugar (*glycose*) in the liver of animals; that in 1855 and 1857 he proved that this sugar is derived from a particular source—glycogen—fixed in the hepatic tissue. Finally, in 1859, he again found this glycogen in the placental organs of mammals and in the vitelline membrane of birds. It is at this point that he recommences the research.

Extraordinary Fecundity.—Dr. Edward Mason reported, at a late meeting of the Elmore Medical and Surgical Society, Wetumpka, Ala., a case in which "a lady bore seventeen children in nineteen years, twice giving birth to twins, and once producing four children at a birth. The latter died, but all the other thirteen survived."

EDITORIAL.

THE ANNUAL REPORT OF THE BOARD OF HEALTH FOR 1871.

WE open the Report of the Board of Health of the City and Port of Philadelphia for the year 1871 with special interest, inasmuch as it treats of a period during which the fearful epidemic of smallpox, the last remnants of which have only just disappeared, took its rise and reached its height.

The report contains forty-nine pages, and to it are added, in the form of an appendix, the reports of the Lazaretto Physician, the physician in charge of the Municipal Hospital, and the Health Officer, making in all one hundred and thirty pages.

The first part, or report proper, contains a very clear and condensed account of the spread of smallpox in our midst, and of the energetic measures adopted by the board to check its progress. There are also, on page 16, some excellent suggestions in reference to the passage of a Sanitary Act similar to that of England, to prevent the use, without previous disinfection, of public conveyances, clothes, bedding, or rooms, which have been used by persons suffering from infectious disease.

There are also recommendations in reference to giving up the use of the impure Delaware water; to the abandonment of surface-drainage; to sewer-ventilation, and to the collection of kitchen garbage; which recommendations it is very much to be regretted that the board has not power or influence enough to cause to be carried into effect.

At page 5 there is an interesting chart exhibiting the course of mortality of the chief fatal diseases of Philadelphia for 1871, and on page 3 a table of the principal causes of death for the year, in which, however, are omitted the deaths from disease of the heart, 547 in number.

In reference to vaccination, every effort seems to have been made to induce all to submit to it, but the absence of a compulsory law rendered it impossible to have vaccination carried out as generally as would be advisable.

In order to get at evidence as to the protection afforded by vaccination or revaccination, the report of Dr. Welch, in charge of the Municipal Hospital, must be referred to. He gives us the statistics of 1227 variolous subjects, among all of which there was only one case of serious disease occurring after revaccination, and in this case Dr. Welch "cannot help entertaining a doubt of the genuineness of the vaccine disease" (see p. 75). One or two of the vaccine physicians also testify to the value of vaccination.

In the printed blanks furnished to all physicians, on which they are by law required to report every case of smallpox as it occurs in their practice, there is a space to be filled up in reference to the previous vaccination of the patient and the character of the mark. This, however, does not appear to have been made use of for purposes of classification; and in reference to the *deaths* from the disease, all such classification would be impossible, for no report as to the vaccination of the patient is required to be made, as it should be, on the blanks issued for reports of deaths.

There are in all, connected with the report, seventeen tables, exhibiting in condensed form most of the important facts in reference to the births, marriages, and deaths in 1871.

The most extended of these tables is No. 6, on page 96, giving the total of interments in the city, and an alphabetical list of the diseases which proved fatal. To this are appended remarks occupying six pages more; which remarks, however, are almost valueless, as they are very little more than a repetition in the same order of the more important points of the table.

If, instead of this, some attempt at classification had been made, so as to give an approximative idea of the total deaths from diseases of the circulatory, respiratory, and digestive symptoms, etc., respectively, the value of the table would have been doubled; for as it is, if an attempt is made, for example, to ascertain the deaths from disease of the heart, we must look under letter A, for aneurism of the heart; C, for congestion; D, for disease and dropsy; E, for enlargement of and effusion on the heart; F, for fatty degeneration; H, for heart-clot, and I, for inflammation of the heart.

Similar useless repetition in the form of remarks is connected with the tables of births and marriages.

A very interesting table on page 125 exhibits the gradual increase of smallpox as shown by the daily return of cases. It goes, however, unnecessarily into particulars. A weekly table would have been just as valuable for the purposes of science, even al-

though it did not show us that the physicians of Philadelphia when they visit a case for the first time on Sunday very often do not report it until Monday. According to the table, very few cases originated on the first day of the week.

The column in this table of totals of cases reported on the first days of all the months throughout the year, as compared with those reported on the second and subsequent days, is valueless. Not even superstition has ever connected an influence with one day of a calendar month as compared with another.

There are very few errata in the report. On page 16, however, we read of patients *which* had smallpox; and on pages 58 and 61 we read about the seventh, eighth, and tenth days of the *rash* of variola.

The report passes in dignified silence over the attacks which have recently been made on the Board of Health. It is not remarkable that, when misfortunes occur, ignorant men should accuse and suspect first of all those who have tried to aid them. In some Eastern countries it is dangerous to help a sick or wounded man found by the roadside, for if he should die, the man last found near him is held responsible. In famines, too, the baker and flour-merchant, without whom every one in a city would be obliged to go himself far into the country for food, are too often the first victims of a stupid populace. What physician, again, has never been held responsible simply because his efforts have been unsuccessful?

So here, unpaid, and hampered by the insufficiency of appropriations, the Board of Health of Philadelphia has been abused by the ignorant, and by those who live by humoring the ignorant of both parties, and by those of no party at all; and, worst of all, the credit for any measures which it may be impossible to find fault with has been taken from them, and claimed as due to the advice of so-called organs of public opinion. But, in spite of all this, the members of the board, with the calm and self-sacrificing spirit of a good conscience, have persevered, and, having done their duty, can look elsewhere for their reward than to the selfish clamor of a popular press.

New Hospital Building.—On the 9th inst., the corner-stone of the new building of the Jewish Hospital Association of Philadelphia was laid, on a lot of ground situated on the Olney Road, near the York Pike. The ceremonies were conducted under the auspices of the Grand Lodge of Free-Masons of Pennsylvania. A Home for the Aged and Infirm will be connected with the institution, in the same building.

ETHER AND CHLOROFORM.

THE constantly recurring accounts of deaths from chloroform seem to have no terror for its advocates, who doubtless honestly believe these accidents to be due to carelessness in administration, or to impurities in the agent itself. Two cases, indeed, have recently been reported, in which the inhalation of sulphuric ether was accused of fatal results. But even if these were correctly construed, which we doubt, can they weigh at all against the hundreds and hundreds in which the lethal effects of chloroform were beyond question? And has this latter any real advantages to offset its fearful risks? Its advocates say that it is easier of administration, more agreeable to the patient, and less apt to induce nausea, than ether; and in certain operations, its non-inflammability is a strong point in its favor. And yet our own experience leads us to doubt whether the safer agent is not in most cases quite as available. Dr. Jeffries, of Boston, we are told, amazed the ophthalmic surgeons in London, at the recent Congress, by showing how easily and how perfectly ether answered the purpose of producing anæsthesia for operations on the eye. We should be glad to receive communications on this most important subject, and on that of anæsthetics generally.

WHAT IS ECLECTICISM?

THIS question seems to trouble the eclectics themselves somewhat; but the Iowa State Eclectic Medical Association tried to settle it by the following resolutions, which "were *unanimously* adopted:

"*Whereas*, The term Eclecticism has been variously construed by different parties, and, whereas, the clear enunciation of our principles from time to time will enable the medical fraternity, and the people, to better understand our system of practice; therefore,

"*Resolved*, As the sense of this convention, that the *total rejection of venesection, arsenic, and antimony, and all their compounds and preparations, as well as lead and copper and all their compounds and preparations*, except as topical applications, are now and ever have been radical and cardinal features of our system of practice.

"*Resolved*, That we doubt the propriety of introducing into the diseased human body, metals which compose no part of it in health, and which are slowly and imperfectly eliminated, and insist on the superiority of organic remedies and those metals found in the normal human body."

If this is all of eclecticism, and if we know anything about the usual practice and prescriptions of regular physicians, the establishment of a special

sect on this basis was hardly necessary. Notwithstanding the constant assertions of quacks of all stripes that their patients have been "bled, leeched, blistered, and purged" by gentlemen whom they are pleased to call "allopaths," venesection is resorted to with extreme rarity at the present day. Except in cases of malignant or semi-malignant disease, and sometimes in obstinate malarial poisoning, we believe arsenic is very seldom employed; while it has proved quite as fatal when used topically as when given by the mouth. Antimony is, in the cities at least, prescribed to a very trifling extent, and copper not at all, for internal use, so far as our knowledge goes. Lead, in very small doses, cautiously administered, is occasionally used in the treatment of dysentery.

We cannot but believe that some of these denouncers of remedies so rarely employed by the regular profession are a little like the Thompsonian who ordered some camphor removed from a sick-room, saying, "None of your *minerals* for me!"

REVIEWS AND BOOK NOTICES.

HAND-BOOK OF SKIN-DISEASES. By Dr. ISIDOR NEUMANN. Translated from the second German edition, with Notes, by LUCIUS D. BULKLEY, A.M., M.D. New York, Appleton & Co., 1872.

It affords us pleasure to comment upon this volume as it now appears,—Americanized. Familiar with the original, we have anxiously awaited the completion of Dr. Bulkley's task, and welcome his translation as a valuable acquisition to our library. Our author was formerly one of Prof. Hebra's assistants in the department for skin-diseases at the Vienna General Hospital, where he at present holds the position of lecturer on these diseases. Throughout Europe, Dr. Neumann has long been recognized as a zealous investigator in dermatology, as well as a ready and easy teacher upon diseases of the skin. With such recommendations we have a right to expect a work of merit.

The basis of the volume is composed of the views of Hebra, which fact is graciously stated in the preface to the first German edition. In Neumann we have a fair exponent of Hebra and his principles, and it is this circumstance which renders the book especially valuable.

Dr. Neumann in his introduction says, "Since the year 1840, Hebra has been making known the principles of the Vienna school, both by writings in the various journals of this and other lands, and by means of his observations and experiences. He who is but superficially acquainted with the 'Handbuch der speciellen Pathologie und Therapie der Hautkrankheiten,' will surely appreciate the simplified nomenclature and clear logic of Hebra, his gift of observation, his precise indications for the employment of remedies, which were in part already in use, and in part were first introduced by himself."

The book before us is a hand-book, and not an exhaustive treatise upon the subject. Commencing with a short history of the early literature, our author devotes a concise and valuable chapter to the microscopical anatomy of the skin. This is a subject rarely comprehended by the student, and will be found particularly satisfactory and lucid. Classification next receives a few pages, and the various systems which from time to time have been devised are briefly enumerated. The system of Hebra—pathologico-anatomical—is given *in extenso*, and it is this classification that our author has taken as a basis and attempted to improve upon. Neumann's system is that of Hebra condensed and simplified. The various anomalies and diseases are discussed in order, being clinically described in a clear and graphic manner. Throughout, the treatment is concisely yet definitely given.

The work is written in a terse, abbreviated style, without superfluity of phraseology, each sentence meaning exactly what the words denote.

Upon certain diseases involved in obscurity, the translator has added appropriate notes, in many cases making the chapters more complete. It has been Dr. Bulkley's good fortune to present to the profession a work which cannot fail to give a wide-spread knowledge of these diseases, and as a manual both for the student and physician we recommend it above all other works of the kind. Scattered throughout the pages are numerous wood-cuts of microscopical sections, which are in every respect equal to the original. The general style of the book is unsurpassable, and the whole presents an inviting appearance which must irresistibly attract attention.

SMALLPOX: THE PREDISPOSING CONDITIONS AND THEIR PREVENTIVES, WITH A SCIENTIFIC EXPOSITION OF VACCINATION. By DR. CARL BOTH. Second edition. Small 8vo, pp. 82. Boston, Alexander Moore, 1872.

The gist of this book is "that smallpox consists in the escape of *superfluous* albuminous substances into the tissues of the periphery of the nervous centres of the body, caused, in the first place, by the want of salt," and "that the *proper* use of salt, in the human economy, will eradicate smallpox at once and forever" (pp. 49, 50). In other words, more salt, and no vaccination. From Serapion and Rhazes down to Aitken, medical writers have wasted time, pens, ink, and paper in trying to get at what Dr. Both's giant mind compresses into one sentence. As to Jenner, the less said about him the better, after this.

BOOKS AND PAMPHLETS RECEIVED.

Evolution of Life. By Henry C. Chapman, M.D. With numerous Lithographic Plates. 8vo. Philadelphia, J. B. Lippincott & Co., 1873.

Ovarian Tumors: their Pathology, Diagnosis, and Treatment, especially by Ovariotomy. By E. Randolph Peaslee, M.D., LL.D., etc. etc. With Fifty-six Illustrations on Wood. 8vo, pp. 551. New York, D. Appleton & Co., 1872.

The Anatomy and Development of Rodent Ulcer. A Boylston Medical Prize Essay for 1872. By J. Collins Warren, M.D. With two Plates. 8vo, pp. 66. Boston, Little, Brown & Co., 1872.

Report of the Philadelphia County Medical Society on Epidemics and Meteorology for the Year 1871. By Laurence Turnbull, M.D., Chairman of Committee. From the Transactions of the Medical Society of the State of Pennsylvania. 8vo, pp. 24.

Transactions of the State Medical Society of Michigan for the Year 1872.

GLEANINGS FROM OUR EXCHANGES.

First Meeting of the German Chirurgical Society (*Berliner Klinische Wochenschrift*, July 8, 1872).—A paper by Heine, of Innsbruck, upon "Parenchymatous Injections for the Dissipation of Tumors," called forth the following remarks from Billroth: "I consider it my duty to call the attention of the society to a case of death resulting from the injection of alcohol into the substance of a struma. Thiersch would have conferred a boon upon science when he first applied this means of treatment to tumors, had the results been what he claimed, and Nussbaum is perhaps right when he says it is the greatest discovery of the age. But I have devoted a great amount of time to experiments of all kinds with injections since Thiersch and Nussbaum first published their work, and especially with a solution of nitrate of silver, as first recommended by Thiersch. The results I obtained were of such a negative character that I desisted."

Subsequently his assistant Czerny, now Professor in Freiburg, made a long series of experiments with injections of tincture of iodine, nitrate of silver, chloride of gold, sesquichloride of iron, carbolic acid, gastric juice, etc. into the substance of struma, lymphatic enlargements, and carcinoma. The results were of such a negative character that they were never published.

Injections into soft tumors, such as medullary lymphoma, usually proved injurious. The same is true, according to Billroth, of the constant electric current, since it produces more rapid circulation, and hence more rapid growth in the tumor, which softens and breaks down sooner than it otherwise would.

Recent communications, however, of Schwalbe, in Zurich, have somewhat modified Billroth's views respecting the use of injections of tincture of iodine, which he thinks may be of great service, as they surely were in a large number of cases treated by Schwalbe.

Although the latter regards alcohol as the most efficacious of all injections, he cites a case of rapid death following its use in a case of carcinoma of the thyroid gland.

Billroth, however, condemns the use of alcohol in the most decided tone, though disposed to relent towards the use of tincture of iodine; and cites a case of rapidly fatal pyæmia following the injection of two hypodermic syringefuls of rectified spirit into a struma upon a woman forty years old.

Imperforate Anus.—J. H. Pooley, M.D., Yonkers, N.Y. (*Am. Journ. Obstetrics*), details thirty-eight cases of imperforate anus, the rectum communicating with the vagina. He remarks in the first place that it is not immediately or necessarily dangerous to life, for one of the patients is stated to have lived a hundred years. Three are stated to have borne children; two were in the habit of sexual intercourse, and their malformation was not discovered until they reached adult life. Others are stated to have reached the ages respectively of twenty, twenty-two, seventeen, and sixteen years. But in all these cases the unnatural opening must have been of unusual size, and in fact is stated in several to have been large enough to admit one or two fingers. These cases are therefore clearly exceptional. For though the fistulous communication may be sufficient to answer the demands of nature and avert danger during the early months of life, yet the danger is always imminent that, as the fæces become more and more abundant and more consistent, a fatal obstruction may occur.

The operation, whatever the special condition may be, consists essentially of two parts: first, to secure and maintain an opening into the bowel at the natural site of the anus; second, to close the unnatural opening into the vagina. The first is far easier of attainment than the other.

Treatment of Imperforate Anus (*Journal de Médecine et de Chirurgie*, tome xliii. part. 2).—Among the operations that may at any moment present themselves to the surgeon, that required for the relief of imperforate anus is one of the most delicate and important, and he should be prepared to meet any difficulties that may present themselves. "We too frequently neglect," says M. Verneuil, "to ask whether the new-born infant has evacuated the urine and meconium; and when it is ascertained that the anus is imperforate, much valuable time has been lost." Thus, he has himself been called upon to operate on the fourth day. He observes that the success of the operation has been made greater in recent times, when, instead of pushing a trocar at hazard in various directions, deliberate dissection has been made. This is particularly requisite where there is no projection of the rectum, or where the inferior extremity of the rectum is altogether absent. A convenient place should be selected, the infant on its belly, with the knees bent and thighs well separated. An incision should then be made from the easily found point of the coccyx, along the median raphé towards the scrotum or vulva. It is important to keep in the middle line, where we find always, as we are taught by embryogeny, in the absence of the rectum, a fibrous band which runs as far as to the membranous region or inferior third of the vagina. This is a valuable guide that must not be lost. When the incision made *layer by layer* is sufficiently deep, there may be perceived, on separating the cut edges of the wound well from each other, and directing a jet of cold water upon them, a small black point not larger than the head of a pin. This is the intestine, and if it be movable it should be drawn towards the skin. It is a fortunate circumstance when this can be done without opening it. More frequently it is only possible to seize the end of the intestine with the hook, and an incision is then made into it. The meconium then flows away, and begins at once to be a source of trouble; its flow sometimes lasts for a considerable period. It must be watched with patience, and waited for till it has finished, in order to complete the operation, which consists in sewing the rectum securely to the skin, taking care that the opening is free, and that there are no chances of retraction or of infiltration. But it may also happen that a deep incision may be made into the perineum, and nothing may be found. The situation becomes a grave one, for it is necessary to continue the dissection into the true pelvis. The operation is difficult, and the guides to it obscure. Not unfrequently the absence of the rectum exists for a considerable portion of its extent. To keep straight in this course across the pelvis, it is important not to lose the walls, the curvature of the sacrum in particular, which is a valuable guide. It is, nevertheless, attended with much difficulty, and M. Verneuil has suggested a proceeding which materially facilitates it. It consists in giving a cut with the scissors on each side of the coccyx, which can then be drawn back, and at once affords greater space to work in. In one instance M. Verneuil found a cut of a quarter of an inch long on either side sufficient, but in others it is necessary to make the incisions more than a quarter of an inch. He has thus succeeded in cases where otherwise the operation would have had to be given up, and some other attempted. Once formed, the retraction and contraction of the new anus should be prevented by directing the mother to introduce the point of the little finger into it several times a day. Most of the cases of imperforate anus prove fatal.

Absence of Spleen.—Dr. Birch Hirschfeld (*Archiv d. Heilk.*, xii. p. 190), of Dresden, found no spleen in

a new-born child which died a few hours after birth. The liver, however, was of an abnormal size, filling the left hypochondriac as completely as the right hypochondriac region, the left lobe being of the same shape and size as the right one. It weighed nearly seven ounces. No trace of the splenic vein or artery could be found.

Alteration of the Muscles caused by Traumatic or Kindred Lesions of the Nerves—Nutrient Action of the Nerve-Centres upon Muscular Tissue (*Centralblatt für Mediz. Wissensch.*, July 13, 1872, No. 29).—Prof. Westphal thus reviews a work of Vulpian, upon the above-mentioned topic, which appeared in the *Comptes Rendus*, 1872, No. 15:

If a spinal nerve, at any point between the spinal ganglion and its peripheral termination, is cut through, the nerve-fibres of the central portion undergo simple atrophy without any further noticeable change in their constituent parts; the fibres of the peripheral portion, however, of the severed nerve undergo the well-known changes (cracking or splitting of the medullary substance, etc.) denominated by Vulpian "histopathic change."

If motor nerves are severed, atrophy of the muscles supplied by them is the result, and if mixed nerves are severed, the electro-muscular contractility is greatly reduced. Vulpian, therefore, propounds the question, Are these changes due to a lesion of the motor, sensory, or sympathetic fibres of which the nerve is composed? Experiments performed by him have already shown that a section of the lingual nerve in the dog is not followed by an atrophy of the tongue, whereas such is the case if the hypoglossal nerve is cut.

The objection can be raised that the hypoglossal contains a certain number of sensory fibres, which are supplied to it by anastomosis, or from its posterior root, since in the dog and some other lower animals the posterior root of the hypoglossal nerve is provided with a ganglion. In order to remove all doubts concerning the anatomical and physiological character of the nerve experimented upon, the section of the facial nerve is adduced.

If this nerve immediately after its origin is severed, we readily obtain a granular degeneration of its fibres throughout its entire course, and the facial muscles undergo all the changes which the muscles of a limb experience after the severance of certain nerves. The facial nerve, however, is without doubt purely a motor nerve at the point of origin, and the supposition that sympathetic fibres arise simultaneously with the motor fibres of the facial nerve cannot be sustained by the anatomical facts. It is therefore a just conclusion that atrophy of the muscles and changes in contractility, after the severance of nerves, may be referred to injuries of the motor fibres. In support of this it may be urged that muscular atrophy is a sequel of disease in the gray portion of the anterior cornua of the spinal cord.

The cause of muscular change cannot be sought in a simply functional paralysis of the nerves, since a series of pathological facts, such as the permanence of nutrition and excitability of the muscles in hemiplegia or paraplegia, after compression of the upper portions of the spinal cord, and other facts, prove the contrary. Neither is an irritation of the nerves and a transmission of the irritation to the muscles a cause of the changes, since the rapidity and intensity of the muscular affection are not proportionate to the intensity of the irritation operating on the nerves. It is, in fact, of little importance, so far as the results are concerned, whether the nerve is severed or only partially cut through, or whether it is torn out, ligated, compressed, or cauterized; although the severance or excision appears to bring about the changes most rapidly and in the most marked manner.

The affection of the muscles cannot be referred to disease or changes in the walls of the vessels, since these remain healthy. In conclusion, it may be said that the disease of the muscles cannot be the simple result of the transmission of a process of disease to the muscles; if such were the case, the muscles should become healthy as soon as the nerves are restored, since the former, like the latter, possess the power of regeneration. Such a regeneration of the muscles does in fact occur if the central and the peripheral portions of the severed nerve are again united; if, however, such a union is rendered impossible, as has been done by Vulpian and Philippeaux in a series of experiments, no regeneration of the muscle occurs.

We must therefore conclude that the gray substance of the spinal centre and its prolongation, or the corresponding parts in the isthmus of the brain, exercise, by means of *motor fibres*, a genuine nutrient influence upon the muscles.

The experimental and clinical facts teach, therefore, that the cause of muscular atrophy, whether it occur in cases of injury of motor nerves or in certain cases of lesion of the spinal cord, must be looked for in the cessation and not in the increase of the nutrient influence of the nuclei in the gray substance from which the motor fibres arise.

Pregnancy at an Advanced Age (*American Practitioner*, September, 1872).—At a meeting of the Louisville College of Physicians and Surgeons, Dr. Turner Anderson reported the case of a woman, aged 51, who was delivered at full term one morning, by a midwife, of a still-born child. The placenta remained. The next day at noon he saw the patient, when he found the uterus well contracted, os dilated, and a small portion of the placenta and the cord protruding. There had been no hemorrhage. On introducing his hand he discovered the upper part of the placenta firmly adherent, while that nearest the os was detached and rolled on itself. With a little manipulation he removed the entire mass. The patient made a good recovery. She had given birth to a living child seven years before. Since that time she had menstruated irregularly. She was exceedingly thin, and her hair was white. Some months before her last confinement, she had consulted Dr. Anderson about an enlargement of her abdomen, which she thought was dropsical. On examination he heard the sounds of the fœtal heart. The patient had never for a moment suspected pregnancy. Dr. Anderson wished to inquire of the Fellows whether they had met with pregnancy in persons of his patient's age or older.

Dr. Speed stated that he was called once to see a lady fifty-three years of age, whose youngest child was nine years old. She had been visited twice that day by a physician of this city, now dead, who had given paregoric for what he said was belly-ache. Dr. Speed found the patient in labor, which ended safely to both mother and child. The woman declared she had no thought of being pregnant.

Eight Children at a Birth.—The *Boston Medical and Surgical Journal* states that, on the 21st of August, Mrs. Timothy Bradlee, of Trumbull County, Ohio, gave birth to eight children,—three boys and five girls. They are all living, and are healthy, but quite small. Mr. Bradlee was married six years ago to Eunice Mowery, who weighed 273 pounds on the day of her marriage. She has given birth to two pairs of twins, and now eight more, making twelve children in six years. Mrs. Bradlee was a triplet, her mother and father being twins, and her grandmother the mother of five pairs of twins.

MISCELLANY.

Parisian Hospitals.—The question whether the new Hôtel-Dieu is to be used for hospital purposes or converted into a building for the city government, has been decided by the municipal council in favor of the former course; but instead of the eight hundred beds which were to have been the limit of its capacity, only four hundred and sixty are to be provided, and certain changes are to be made in the original plan. The Hôpital Berck, which was built on the sea-shore for the accommodation of strumous children, has also proven an "elephant," for, besides the very considerable expense of its construction, the municipal council have just been obliged to appropriate 25,000 francs to works intended to protect it from invasion by the sea.

A novel proposal has been made by two medical men—Drs. Thulié and Marmottan—for the utilization of the Hôtel-Dieu. They suggest that the old portion of the hospital, on the left bank of the river, should be retained as a hospital, for two hundred patients; and that the new portion should be sold to a company—French or foreign—for the purpose of forming docks like those which exist on the borders of the Thames in London. They further point out, that of twenty-two *octroi* barracks around Paris, four are unoccupied, and may be readily put into repair as hospitals capable each of containing one hundred beds. To make up the number of eight hundred beds which are required, they propose the erection of a new hospital to receive two hundred patients. Whether this plan would be attended by the financial success which its promoters allege that it would have, we do not pretend to judge; but there can be no doubt that, in a sanitary point of view, the distribution of eight hundred patients would be preferable to their aggregation in one building.

Chloroform among the Chinese.—According to a reputed discovery by M. Stanislaus Julien, it appears that as far back as the third century of our era, the Chinese were in possession of an anæsthetic agent which they employed in the same manner as we use chloroform and ether, for producing insensibility during surgical operations. A description of this was discovered by M. Julien, in a work preserved in the "Bibliothèque Nationale"—called "Kou-kin-i-tong," or a "General Collection of Ancient and Modern Medicines"—which appears to have been published in the sixteenth century. In a biographical notice of Hoa-tho—who flourished under the dynasty of Wei, between the years 220 and 230 of our era—it is stated that he gave the sick a preparation of *chanvre* (Indian hemp), "Ma-yo," who in a few moments became as insensible as one plunged in drunkenness or deprived of life; then, according to the case, he made incisions, amputations, and the like. After a certain number of days the patient found himself re-established, without having experienced during the operation the slightest pain. It appears from the biography of Hoa that this *chanvre* was prepared by boiling and distillation.

Home for Middle-class Incurables.—In connection with Mrs. Gladstone's Convalescent Home, a very excellent institution was experimentally inaugurated in April last, in Brook Road, Upper Clapton, namely, an incurable-hospital for the poor middle-class. We say experimentally inaugurated, for, to insure the success of the institution, immediate and steady public support was required. It was determined to gauge its probable success by a six months' trial, and accordingly two adjoining houses were acquired at Upper Clapton for the purposes of the undertaking, in an open and detached position. The houses contain a number of small rooms, and are capable of accommodating from twenty to thirty patients. The total sum fixed upon to be paid by each patient is £20 per annum. Dr. Gardiner attends as medical officer. A comfortable home is thus placed within the reach of many incurable persons of the poor middle-class who are unable to meet the pecuniary demands and consequent discomforts of a prolonged and progressive illness. The institution has now been opened nearly five months, and it has met with only partial success; no doubt in consequence of its obscurity. It did indeed rather strangely and happily fulfil its mission during one month of its career, in affording a temporary home to the patients of the cancer-wards of the Middlesex Hospital, which, during August, was undergoing repairs.

The posting of placards of quack medicines has been prohibited in the streets of Chicago.

The Plague in Persia.—The pestilence which has been raging in Persia for two years past is said to be the true Oriental plague, marked by high fever, cerebral symptoms, buboes on the neck, in the armpits and groins, petechial spots, purpura, carbuncles, etc. The mortality averages fifty per cent., death occurring in from three to eight days. Whole villages have literally been depopulated. In cold weather it disappears.

Holloway's Hospital.—We learn from the *British Medical Journal* that Mr. Holloway, famous for his pills and ointment, is about to erect, at his own expense, a large hospital at Virginia Water. It will cost from £70,000 to £100,000, and will accommodate two hundred patients. It will be maintained for a year by Mr. Holloway, after which it is expected to be self-supporting, and will be handed over to the management of trustees.

Vaccination Objection.—A small boy in an Indiana town made several applications to be protected against the scourge of smallpox. Finally his physician was able to accommodate him with an excellent "scab" from a healthy boy; but when the patient found where it came from, he objected to the application being made for fear he would "stutter," as the boy who furnished the material was addicted to that method of articulating.

Dr. J. Baker Brown, the celebrated gynæcologist, has become paralyzed, and is in great pecuniary distress. A fund is being collected for him in London, of which Dr. Forbes Winslow is the Treasurer.

ALDINI PRIZE ON ELECTRICITY.—The Academy of Sciences in Bologna has announced that a prize of 1200 *lire* (£48) will be awarded to the author of the best scientific experimental essay on galvanism or dynamic electricity. Essays intended for the competition must be sent in between July 1, 1872, and June 30, 1874, and must be written in Italian, Latin, or French. They may be either written or printed; but, in the latter case, must not have been published previous to the two years above mentioned. Each essay is to bear a motto, and to be accompanied with an envelope stating the name of the author. They must be addressed to the Perpetual Secretary of the Academy of Sciences of the Bologna Institution.

A HOMŒOPATHIC reviewer, noticing Dr. H. C. Wood's "Year-Book of Therapeutics, Pharmacy, and the Allied Sciences," compares it with the "Annual Record of Homœopathic Literature," and says, "To the true and progressive physician both these works will become one, and will find places side by side in his library. The active practitioner knows only too well how acceptable is a word fitly spoken, even if it does not agree with his own confession of faith." Either "*similia similibus curantur*" holds good,—and Dr. Wood's book has nothing either based upon it or supporting it,—or it does not, and homœopathy is a humbug.

PERSONAL.—Dr. William Keller, after an absence of eleven years in Germany, has returned to this city to practise medicine.

Dr. Gotthilf Moehring, a well-known and much-respected physician of this city, who went abroad to live last autumn, is here at present on a visit.

The College of Physicians of Philadelphia has lost a valued Fellow in Dr. George Pepper, whose death occurred early in September.

The celebrated Dr. Louis, of Paris, who died recently at the great age of eighty-six years, was an Associate Fellow of the College.

THE ASTLEY COOPER PRIZE.—The next triennial award of this prize of £500 will be made to the author of the best essay on "Injuries and Diseases of the Spinal Cord." Essays must be sent to Guy's Hospital before January 1, 1874.

IMPERIAL GOOD WILL.—The Emperor of Austria has contributed 20,000 florins towards the International Congress of Medical Hygiene, to be held in 1873.

THE London medical profession has lately sustained the loss of two of its leading members,—Mr. F. C. Skey and Mr. Alfred Poland. Both of these gentlemen have been well known on this side of the Atlantic by their writings. Mr. Skey was President of the Royal College of Surgeons.

IN a recent number of *Le Mouvement Médical*, it is stated that in three days, "in the cities of New York, Brooklyn, and New Jersey," four hundred and eighty deaths occurred from the extreme heat.

WHEN Coleridge was asked what was "the use" of a certain new scientific discovery, he retorted by asking, "What is the use of a new born child?"

MORTALITY OF PHILADELPHIA.—The deaths reported at the Health Office for the week ending October 12, 1872, were 249; of which 144 were of adults, and 105 of minors. Among the causes assigned were:

Consumption of the Lungs	47
Other Diseases of the Respiratory Organs	10
Diseases of the Circulatory Apparatus*	15
Diseases of the Brain and Nervous System	33
Zymotic Diseases	17
Typhoid Fever	11
Casualties	9
Dysentery	3
Inflammation of Stomach and Bowels	5
Cholera Infantum	3
Debility (including "Inanition" and "Marasmus")	30
Old Age	7
Stillborn	14

* One case of "Rupture of the Heart."

OFFICIAL LIST

OF CHANGES OF STATIONS AND DUTIES OF OFFICERS OF THE MEDICAL DEPARTMENT U. S. ARMY, FROM SEPTEMBER 19, 1872, TO OCTOBER 4, 1872, INCLUSIVE.

EDWARDS, L. A., SURGEON.—To report in person on 2d of October next, to the Commanding General Department of the Lakes, for assignment to duty. S. O. 227, War Department, A. G. O., Sept. 25, 1872.

GODDARD, C. E., SURGEON.—Relieved from duty at Fort Rice, D. T., upon arrival of Assistant-Surgeon Williams, and to comply with S. O. 167, c. s., War Department, S. O. 184, Department of Dakota, September 16, 1872.

WILLIAMS, J. W., ASSISTANT-SURGEON.—Assigned to duty at Fort Rice, D. T., S. O. 184, c. s., Department of Dakota.

NOTSON, WILLIAM M., ASSISTANT-SURGEON.—Granted leave of absence for thirty days, S. O. 101, Department of the Lakes, September 26, 1872.

WATERS, WILLIAM E., ASSISTANT-SURGEON.—Relieved from duty in Department of the East, and to report in person to the Commanding General, Department of the Missouri, for assignment. S. O. 218, War Department, A. G. O., Sept. 18, 1872.

BREWER, J. W., ASSISTANT-SURGEON.—Relieved from duty at Fort Walker, and assigned to duty at Camp Supply, Indian Territory, S. O. 151, Department of the Missouri, Sept. 18, 1872.

GARDNER, W. H., ASSISTANT-SURGEON.—Assigned to duty with troops constituting garrison of Fort Riley, Kansas, to proceed to camp 6th Cavalry, near Fort Hays, Kansas, and report to the Commanding Officer for duty. S. O. 155, Department of the Missouri, Sept. 26, 1872.

BROWN, H. E., ASSISTANT-SURGEON.—Directed to leave New Orleans, La., on 10th of October next, and to proceed to Washington, via New York City. S. O. 224, War Department, A. G. O., Sept. 23, 1872.

JESSOP, S. S., ASSISTANT-SURGEON.—Relieved from duty with 6th Cavalry, and assigned to duty at Fort Selden, N. M. S. O. 155, c. s., Department of the Missouri.

VICKERY, R. S., ASSISTANT-SURGEON.—When relieved by Assistant-Surgeon De Hanne, to comply with S. O. 205, c. s., War Department, S. O. 158, Department of the Missouri, Sept. 30, 1872.

DE HANNE, J. V., ASSISTANT-SURGEON.—Relieved from duty as Attending Surgeon at these Headquarters, and assigned to duty as Post Surgeon, Fort Wingate, N. M. S. O. 158, Department of the Missouri, Sept. 30, 1872.

DELANY, A., ASSISTANT-SURGEON.—When relieved by Assistant-Surgeon Jessop, to comply with S O. 205, c. s., War Department, S. O. 155, c. s., Department of the Missouri.

COWDREY, S. G., ASSISTANT-SURGEON.—Relieved from duty at Camp Supply, Indian Territory, and assigned to duty at Fort Larned, Kansas. S. O. 151, c. s., Department of the Missouri.

REYNOLDS, F., ASSISTANT-SURGEON.—To report in person to the Attending Surgeon, Portland, Oregon, for medical treatment. S. O. 113, Department of the Columbia, Sept. 11, 1872.

ASCH, M. J., ASSISTANT-SURGEON.—Granted extension of leave of absence until March 31, 1873, and his resignation accepted by the President, to take effect March 31, 1873. S. O. 224, War Department, A. G. O., Sept. 23, 1872.

SATURDAY, OCTOBER 26, 1872.

ORIGINAL COMMUNICATIONS.

A FEW UNUSUAL SURGICAL CASES.

BY WILLIAM HUNT, M.D.,
Surgeon to the Pennsylvania Hospital.

DURING the last two or three terms of my service at the Pennsylvania Hospital, some cases entirely out of the usual run have occurred, which I think are worthy of record. As they are very definite in character, I relate them without tedious detail of dates and special symptoms, for if required these can be obtained from the record and from private notes.

1. *Gunshot Wound of Innominate Bone and Head of Femur; Necrosis of the Head and Removal of it. Recovery.*

A boy about eighteen years of age, living somewhere in Illinois, I think, drew his gun, loaded with shot, towards him by the muzzle; it went off, and the charge was received over the outer portion of the left groin, and must have fractured the iliac bone and head of the femur. The boy was under treatment for a long time, and was finally brought to Philadelphia and admitted into the hospital. He was helpless, and very much reduced from abscess at the seat of injury. The right leg was shortened and everted, there were deep sinuses with small external openings in the groin and through the glutei and upon the external aspect over the trochanter. Examination with the probe demonstrated the existence of large pieces of loose bone, apparently in the cavity of the joint. I made a large and deep semilunar incision above the trochanter, introduced the bone forceps, and drew out the *necrosed head of the femur* and several other fragments evidently from the ileum. Examination with the finger showed the cavity to be clean, and the openings afforded abundance of room for drainage in every direction. The limb was supported by sand-bags, and the foot secured to the bed. Very rapid improvement took place, and in a few weeks the patient was up and moving about with crutches. Within two months the sinuses were entirely healed, and shortly afterwards he was discharged in first-rate condition, merely requiring the use of a cane for walking.

The early history of this case is obscure. The patient stated that the fractures were not recognized at the time of the injury, or at least, if so, he did not know it. It is scarcely credible to me that this extensive separation of fragments of bone was altogether secondary. In fact, the large masses of callus about the anterior superior spine would point to original fracture; and if so, this is a striking instance of the wisdom of delay (although in this case unintentional) before attempting the excision of the hip-joint in cases of acute and extensive injury.

2. *Fracture of Neck of Femur completely within the Capsule in a Young Man, apparently from a Direct Blow.—Curious Ability to Walk after the Injury.—Death from Pelvic Abscess.*

On an afternoon of June, 1871, a man twenty-six years of age, complaining of injury to his hip, *walked* into the lower ward of the hospital. He was regarded there as having a contusion, and was sent to the third-story ward. He required some assistance to mount the stairs, and suffered considerable pain in doing it. He stated that the day before, whilst working at a bridge on the Media Railroad, a heavy wooden girder had fallen and struck him violently across the upper portion of the left thigh and groin. He fell to the ground and was carried to a shanty, where he remained all night, suffering a great deal of pain. The next morning with some assistance he *walked* to the steam train, got off it at Philadelphia and into a street-car at the station. He rode to the nearest point to the hospital gate, and then, with the aid of a stick only, *walked* to it, a distance of nearly two hundred and fifty yards. His progress to the ward is stated above.

The patient was placed in bed and examined, but no positive diagnosis was arrived at, and my attention was called to him on the following day.

Ether was provided; but, without its use and notwithstanding the history, I made out that there was fracture of the neck of the bone. There was eversion, shortening to the extent of half an inch, and deep but unmistakable crepitus. There was a large bruise upon the upper and outer aspect of the thigh, over the trochanter and anterior superior spinous process.

The adhesive strap extension and lateral support with sand-bags were applied, to the great relief of the patient, who progressed favorably for about twelve days, when considerable fulness was detected along the line of Poupart's ligament. Great pain was complained of, and symptoms of pelvic abscess soon declared themselves.

There was fever, with accompanying nausea, vomiting, and sweats; obscure fluctuation was soon apparent, and an exploratory puncture brought out some thin pus and broken-down blood.

The patient sank rapidly, with pyæmic symptoms, and died on the twenty-seventh day from the date of his injury.

Besides the lesions of the viscera that accompany pyæmia, there was recent local peritonitis in the left iliac region, the tissues of which were involved in an abscess.

The innominate bone was not fractured, but the neck of the femur immediately *behind the head was broken directly across*, the lines of fracture being completely within the capsule of the joint.

This case is remarkable from two circumstances: one, the youth of the patient; of forty fractures of the neck of the bone spoken of by Hamilton, excepting one case of supposed epiphyseal separation, the youngest was thirty-nine years of age.* Second, the same authority also says that fracture of the neck of the femur from a direct blow is a very rare circumstance. "Indeed," he says, "it can only happen as the result of gunshot accidents or other similar penetrating injuries."

It may be said that the fracture in this case was produced by the fall after the blow was received; but the injury of other parts immediately in the neighborhood of the bone was so great as to fully demonstrate the violence that was sustained, and to render it highly probable, I think, that the fracture also occurred at the same time.

Was this an impacted fracture? How else shall we explain the ability to walk? But would an im-

*[Mr. Stanley's celebrated case, intracapsular with bony union (see *Med.-Chir. Transactions*, vol. xviii.), was that of a boy of eighteen.—ED.]

pacted fracture be likely to resolve itself so early as the second day after the injury was received, so as to make the fragments easily movable on each other? Is it possible that the fracture was so close to the head as to allow the neck to rest against the edge of the acetabulum, and thus give temporary support?

3. *Astragalo-scaphoid Luxation with Twist of the Astragalus. Reduction and Recovery.*

One evening I received a note from my resident, stating that "he had never seen such a case as had just come into his ward," and requesting a visit from me. I immediately went down, and found a case the like of which I also had never seen, although it was not unique.

A young man from twenty to twenty-five years of age, the driver of an express-wagon, had a horse to fall upon him. He was unable to rise without assistance, and was brought to the hospital. The injury was of the right foot.

The deformity was very peculiar. The portion in front of the ankle was strongly everted, while almost immediately under the internal malleolus was a rounded projection with the skin very much tightened over it, which upon examination proved to be the head of the astragalus completely thrown off from the scaphoid, and so twisted that a line projected from the centre of it would pass across the middle of the opposite foot, instead of through the great toe of the same side.

The parts were almost immovable before etherization. After the patient was most thoroughly under the influence of the anæsthetic, I made a careful examination of the relations of the parts. With the aid of two assistants, one at the foot, and the other at the leg below the knee, flexing and extending according to directions, I had the good fortune to suddenly manipulate everything into place. The parts were then very freely leeched, cold was applied, and the limb put to rest in a fracture-box.

There was great swelling afterwards, but this subsided, and in four or five weeks the patient was allowed to get up, having the parts well supported by a silicate bandage. He was soon ready for discharge, and I have since seen him about the streets engaged at his former business.

4. *Foreign Body in the Bladder.*

A youth with some very peculiar ideas tied a string to one of the galvanized watch-chain catches that are worn through the vest button-hole, and then passed it down his urethra. It suddenly slipped into the bladder, the string hanging out of the orifice of the urethra. On inquiry, I found that the tie was unfortunately at the middle of the object, and hence this presented itself crosswise when it was drawn to the neck of the bladder. Various efforts were made with different instruments to catch the body in the right direction, but all in vain; and at last the string, which had been a good guide, broke.

After a few more trials at seizure without success, I concluded that enough had been done at one sitting, and that, if not successful in other ways, lithotomy would have to be resorted to.

One other way was tried. It was this: I directed the boy to drink very freely of flax-seed tea and nitre, and to hold his water as long as he possibly could, and then, at the very first effort, to drive his stream with all the force he was capable of, in the hope that the body might present longitudinally and be forced out. These directions were followed strictly and with complete success.

At the first urination, the object was shot out against the side of the vessel, and the patient was at once relieved.

5. *Refracture of the Bones of the Leg, and Tenotomy for the Cure of very faulty Union. Recovery.*

A sailor, aged thirty-seven, was admitted to the hospital on the 19th of February, 1872. He could scarcely walk, and for practical purposes his left leg was almost useless. He stated that some time in the summer of 1871 he had fallen from the rigging while at sea, and besides breaking both bones of the left leg about the middle, he was severely hurt about the hip of the same side, although there was no fracture in this latter position. He was on the ship for nearly three weeks, was then removed to a hospital in Liverpool, where he remained for some months, was then discharged and came to this country.

Remarkably firm bony union had taken place at the seat of fracture. There was great angular deformity, and the foot was in the position of marked equinovarus, the sole presenting towards the opposite side, the heel raised, and but a limited portion of the internal edge of the foot capable of being brought to the ground. There was a large cicatrix on the outer aspect of the hip-joint, the movements of which were impeded by adhesions.

The patient stated that he came in to get relief in any form possible, and was willing to submit to amputation, or to any effort to save the limb and make it useful, even at the risk of his life.

His general condition was bad, and shortly after admission he had a severe attack of sore throat, from which he was some time in recovering.

It was concluded on consultation to make an effort to save the limb by refracture and tenotomy.

The patient was placed on the table and etherized. A large-sized drill was then applied to the tibia through a small external incision. I bored completely through the bone in three or four different directions, immediately at the seat of fracture, withdrawing and entering always at the same external opening.

Then bringing the limb over the edge of the table for a fulcrum, it was broken by the united efforts of myself and colleagues, Drs. Hewson and Morton. The force required was all that we could put on, and when the bone broke, it was with a surprisingly loud and sharp crack, not unlike the report of a pistol.

The tendo Achillis was then divided, the stiffness of the hip was removed by breaking up the adhesions, and the whole limb could be brought in good position with very little shortening.

A stout pasteboard splint, well fitted to the external aspect of the foot and leg, was applied; a moderate degree of extension by adhesive strips was maintained, and strips also were used to keep the foot in a position of slight eversion. The extension was abandoned after a short time as not requisite, and the limb with the other dressing complete was placed in a fracture-box.

The wounds were dressed with plaster, and to the one over the fracture, water was applied.

There was of course great shock at first, but when this passed off, the case went on very favorably for about six weeks. There was slight suppuration, and I removed several small pieces of dead bone from the wound. After this the patient had a very severe attack of what appeared to be hepatitis and pleurisy combined, and at the same time there was formed at the wound over the fracture an ugly, deep, gangrenous slough. From the appearances, and calling to mind the attack of sore throat before operation, I had suspicions of syphilitic contamination, and directed iodide of potassium and bichloride of mercury.

For a time life was despaired of, as his condition was

extreme. Gradually, however, amelioration of all the symptoms took place, the slough separated, leaving a healthy ulcer, and I was surprised to find that the progress of union of bone had not been in the least interfered with by the attack.

When I left duty on the 1st of August, the patient was able to walk, bringing the foot flat to the ground, and to perform all natural movements with the limb. Union was solid, the tendo Achillis had been repaired, and the motions of the hip were restored.

He called on me a few days ago (October 1), perfectly well. A slight limp was perceptible, owing possibly to the shortening (not more than one-fourth inch), and he is in every way as well as he would be had he made an ordinary recovery from the original injury.

NOTES OF HOSPITAL PRACTICE.

JEFFERSON MEDICAL COLLEGE.

CLINIC OF PROF. S. D. GROSS, M.D.

Reported by FRANK WOODBURY.

FOREIGN BODY IN THE ŒSOPHAGUS.

A BOY, three years of age, was brought before the clinic, September 7, who had, while playing about five months before, accidentally swallowed a cent and a three-cent piece. The copper coin shortly afterwards passed through the bowels, but the three-cent piece remained. Since the date of the accident the child has been unable to eat solid food, because, in the attempt at swallowing, it was rejected by an act of regurgitation from the œsophagus; he has consequently been subsisting exclusively upon broths and milk. He has also some trouble in breathing, which at times is greater than others.

This coin has evidently been retained in the œsophagus instead of passing into the stomach, but nothing can be seen of it on looking down the throat. We will have this patient return for operation, and then endeavor to force the coin downward into the stomach, with a probang. It may afterwards be unable to pass the pylorus, or may cause trouble in the bowel, for which we cannot be responsible.

Foreign substances generally come in this situation from the food, such as the small bones of chicken or fish, pieces of meat or gristle, etc. Artificial teeth are sometimes swallowed, and lodge here. Ladies are very fond of putting pins in their mouths, and these frequently find their way into the œsophagus. These obstructions generally produce great uneasiness, alteration of voice, and, occasionally, difficulty of breathing from spasm of the glottis. Large substances have produced strangulation, in the same manner as if contained in the trachea.

When you are called to a case of this kind, the first indication is to remove the offending substance. If it is visible, it may be extracted with the fingers or with a pair of polypus forceps, in order to do which an anæsthetic may be necessary. The direct emetics, such as the sulphates of zinc and copper, and mustard with plenty of warm water, will often be successful in expelling the offender. A case is on record where, the patient being unable to swallow, the surgeon administered an emetic through a gum-elastic catheter; this was followed by prompt emesis, forcibly expelling the substance. It is a remarkable and important point that, after the article is extruded, the irritation may remain for some time, giving the impression that the substance is still present; this may remain for several days or even weeks. The philosophy of this is exactly the same as in that trick of legerdemain where a coin is pressed strongly into the palm of your hand for an instant, and adroitly removed as the hand is closing, leaving such a strong impression that you are absolutely certain that the coin is still there, until you open the hand and find it has disappeared.

In removing the offending article from the throat by means of instruments, some care must be exercised. A case in point occurred some years ago in Cincinnati, where a woman, supposing that she had swallowed a pin, was attended by a physician, who endeavored to extract it with an ordinary dress-hook, fastened to the end of a piece of whalebone. He failed to find the pin, but in his efforts he lacerated the mucous lining of the pharynx and œsophagus so severely, that the patient died from the ensuing inflammation. Some years ago I devised a special instrument for the purpose of removing articles from this situation. It consists of a curved steel rod, about fifteen inches long, covering a stylet surmounted at its extremity by four wing-like processes, which are closed and expanded by turning the handle of the instrument. When the article cannot be extracted or consists of digestible substance, we may push it into the stomach with a probang. The foreign substance may, after a time, become buried in the wall of the œsophagus, and so offer no obstruction to the instrument, which passes directly into the stomach. This possibility should lead us to be careful in our diagnosis; many such cases are recorded where nothing, during life, could be detected, though all the rational signs were present, but at the post-mortem examination the substance was discovered concealed in this way.

If the offending body is immovable, the œsophagus may be opened in the neck, by an incision, commencing on a level with the superior border of the thyroid cartilage and running downwards, parallel with the sterno-cleido-mastoid muscle. After the tube is opened and the substance extracted, the edges of the œsophageal wound are brought together by the interrupted suture, using silk threads, which are afterwards cut short so as to allow them to ulcerate through into the passage. The patient is then supported for a couple of weeks on strong meat soups, introduced by a tube into the stomach, or, which is better, injected into the rectum. The results from this operation have been very encouraging. When all reasonable attempts at extraction fail, the best plan is to resort at once to the knife; otherwise, complications may arise, interfering with the success of the operation, and endangering the patient's life.

A CASE OF ANKYLOBLEPHARON.

In this patient, a girl twelve years old, there has been severe inflammation of the eye, followed by impairment of vision and adhesion of the lower eyelid to the ball. This is not only disfiguring, but prevents the adjustment of an artificial eye, therefore calling for operation.

This affection is usually produced by scalds and burns, or by the contact of the stronger acids or quicklime. After administering chloroform, we shall proceed to dissect apart the morbid adhesion of the two contiguous conjunctival surfaces, and to prevent their reuniting will introduce a piece of lead-foil cut to fit the part. The lids will then be brought together, and held with isinglass plaster. The cure will require three or four weeks, during which time the foil will be removed and cleansed daily, and the eye carefully washed before replacing it.

STRUMOUS ENLARGEMENT OF THE ANKLE-JOINT.

A pale, poorly-developed boy of six years, was brought to the clinic by his father, on account of a chronic swelling of the ankle-joint of the right foot. About eighteen months before, he first experienced difficulty in walking, and the joint became swollen, painful, and easily fatigued; all of these symptoms being attributed to a supposed sprain. But they have not subsided under the usual remedies, the condition remaining permanent. His father is a very nervous man, but says he never had any sickness or disease, and thinks there is no scrofula in the family. The little patient is restless at night, and screams and starts in his sleep. His appetite is capricious; the tongue is not much coated.

On examining the child's limbs, we find the affected joint manifestly much larger than the left one. With the hand applied over its surface, we notice that it is four or five degrees warmer than its fellow, indicating, by this elevation of temperature, that inflammation is present. The joint is tumefied, but the deformity and induration are mainly produced by strumous enlargement of the lower ends of the tibia and fibula. The patient is thin and puny; his countenance, which is sallow and anæmic, wears an uneasy expression. He has the light complexion and light hair of scrofulous subjects, and we find the cervical glands enlarged. This affection is a case of tubercular disease of the joint, or white swelling, as it is commonly called; often seen in scrofulous children, frequently in the form of hip-joint disease or coxalgia. The cutaneous veins are enlarged around the joint, as they very generally are in cases of this kind. The swelling present is not due to effusion of serum or lymph in the tissues around the joint, but is within the joint itself, being produced by a morbid increase of the natural moisture of the joint. Let us examine the structure of a joint. We have the contiguous articular cartilages and capsular ligament, lined by a synovial membrane, which, in health, is quite delicate and secretes just enough moisture or halitus to lubricate the opposing surfaces. When in a state of inflammation, this fluid is poured out in excessive quantity, so as to distend the capsular ligament and stretch the other ligaments in every direction. In such a case the fluid in the joint is clear and pellucid, with, perhaps, a few flakes of unorganized lymph floating in it, but contains no pus. When the morbid action is of a strumous character, this synovial membrane sometimes becomes enormously enlarged, and the articular cartilages, being intimately connected with this membrane, participate in the disease. It has been gravely stated, by some writers, that these cartilages are without vessels and nerves. This is absurd. You can disprove it at any time by going to a butcher and making a section of a fresh joint. Where the morbid action starts, whether in the cartilage or synovial membrane, is a mooted question. But wherever it commences, we know that it ultimately involves all the structures of the joint, including the bone, which becomes eroded. After the disease has existed as long as it has in the present case, it is entirely out of the question to expect that the proper function of the joint can ever be entirely restored to the patient; but he may have a useful foot. During all the time the disease has been in progress, he has been using the ankle and the joint has been constantly in motion. Here are two surfaces in a state of inflammation, that have been rubbed together more or less rudely when they should have been kept perfectly quiet. If you had an inflamed finger, would you use it? No; because if you did, the pain and aggravation of the morbid action would warn you to keep it at rest and in an elevated position, so as to hasten the reflux of blood from the part, and relieve the passive congestion produced by gravitation. Nor would you use an inflamed eye; you would avoid anything that would irritate it; and this applies especially to a joint in this condition. Then what shall be the treatment? Rest, as perfect as can be attained, which is absolutely essential to a speedy cure. To secure this, we will order the limb to be encased in a splint, or in an instrument so constructed as to keep the foot a little relaxed and the joint perfectly quiet. As inflammation is present, the foot must be kept elevated and wrapped in a strong solution of acetate of lead. He must keep his bed for the present, and not attempt to use the joint until the morbid action is controlled. His diet will be nourishing: eggs, milk, stale bread, mutton-broth, tenderloin-steak rare broiled, vegetables and fruit. If he has pain at night, we will give him six or eight drops of laudanum as an anodyne. He may take as a tonic:

℞ Quiniæ sulphat., gr. j;
Acid. sulphuric. aromat., gtt. j;
Tinct. ferri chlorid., gtt. x. M.

thrice daily.

If this were an adult, we might apply a large blister over the joint so as to stimulate the absorbent vessels; but at this tender age we must be careful, as we might excite severe action that would be difficult to control. Tincture of iodine is also useful for the same purpose, but we will not apply it here.

OPERATION FOR HARE-LIP.

The affection existing in this infant is known as simple hare-lip; if it existed on both sides of the median line it would be called double hare-lip, deriving its name from the supposed resemblance it bears to the upper lip of the hare. Some writers speak of it as occasionally existing in the lower lip, but I have never seen it there, and consider this a misstatement. Curiously enough, this condition is frequently hereditary, being traceable backward, in some cases, for several generations. It is congenital in its origin, having the same pathology as cleft palate, spina bifida, congenital hernia, exstrophy of the bladder, or deficiency of the anterior wall of the abdomen with eversion of the bladder. These are all analogous affections, being due to an arrest of development of special parts, for reasons which I am unable to give.

As to the proper age for operating; you should always operate upon a healthy infant as early as possible. This little girl is thirteen weeks old, but in several instances, where the child was well nourished and healthy, I have performed the operation within a few days after birth. Of course, if the child is puny, anæmic, or sickly, you would defer such interference until it was better able to sustain the shock and loss of blood. The existence of a co-existing cleft in the jaw is a strong inducement to operate early, as the pressure of the tightened lip upon the bone always promotes early closure. Never operate if the child has a cough.

The surgeon, in operating, holds the child's head firmly between his knees; the body, wrapped in a sheet, being confided to an assistant. Three steps are to be taken: first, separate the lip from the gum and alveolar processes, as far up as the nose, if necessary to get the proper amount of material; second, pare the edges of the fissure so as to produce raw surfaces for coaptation; and third, approximate the edges by the twisted suture or by pins surrounded by a waxed ligature, in an elliptical form, not in a figure-of-eight, as recommended by some writers. The points of the pins are then removed with the pliers.

The child should be put to the breast immediately after the operation; if it appears to suffer much pain, we will give it a drop or two of laudanum. The upper and middle pins are withdrawn at the end of forty-eight hours, the lowest one remaining a day longer. We do not take away the thread, as, with the exuded

lymph, it acts as adhesive plaster, and will be left to support the part until it comes away of itself.

The operation was then performed; no chloroform was given. If the subsequent inflammation should tend to run high, a little aperient medicine was directed to be administered, and a cold-water dressing applied to the part.

INJURY OF FINGER FOLLOWED BY NECROSIS.

This patient, a man thirty-eight years of age, had the third finger of his left hand accidentally crushed in a machine about six weeks before. Violent inflammation supervened, accompanied by severe pain, exhausting and depressing his nervous system, destroying his appetite, and preventing sleep. The second phalangeal joint was laid open, its structure destroyed by the morbid action, and necrosis of the first and second phalanges followed. The finger is now tumefied, hot, discolored and painful, showing the presence of inflammation. There is a large sinus leading into the joint, which discharges unhealthy pus mingled with small particles of bone.

The question now is, Would it be better to attempt to moderate the morbid action and save the finger, or to remove it at once? If this patient were a lady, we would wish to avoid deformity; the presence of a finger, even though stiff, would be far preferable to its removal; but in a working-man, who uses his hands to earn his living, the stiff finger would be in his way, and would constantly be bruised and injured. Therefore, in such a case I always consider amputation as perfectly proper and justifiable.

Amputation of the finger at its junction with the metacarpal bone is easily performed by making two incisions, commencing at the centre of the knuckle, which, gradually diverging, circumscribe the finger and meet on its palmar surface in a line parallel with the web of the adjacent digits. The finger is forcibly flexed during disarticulation, so that the extensor tendon may be severed above the joint; otherwise it might interfere with the stump. The projecting part of the metacarpal bone should be removed with the bone-forceps, in order to give a more seemly appearance. During the after-treatment, a splint must be applied and the adjoining fingers kept separated; otherwise they may overlap each other, thus producing deformity and interfering with their usefulness.

Chloroform was administered and the operation performed. The danger that now threatens our patient is tetanus, which may indeed follow any wound; erysipelas may also be a complication; but these need not deter us from an operation if we have taken all the precautions in our power to protect our patient and obtain a successful result. Having done this, we have performed our duty, and must leave the rest with Providence.

[The operation was followed by a speedy recovery, without any untoward symptoms. On dissecting the joint, the articular cartilages and the synovial membrane were found to be entirely destroyed and the bone eroded; the amputation, therefore, was eminently proper and necessary.]

WILLS OPHTHALMIC HOSPITAL.

SERVICE OF GEORGE C. HARLAN, M.D.

Reported by CHARLES K. MILLS, M.D.

TWO CASES OF SYMPATHETIC OPHTHALMIA.

H. S., æt. 23, two years before his appearance at the hospital, was struck in the right eye with a slung-shot, and had ever since been blind in this eye, in which also he had had almost constant pain and inflammation. The ocular conjunctiva was greatly engorged; a dense opacity covered the whole of the cornea, and there were cicatricial evidences of a rupture in the sclerotic near the corneal margin. He stated that since the injury he had used a great variety of eye-washes, prescribed by different doctors, but with only slight temporary benefit.

The left eye had been "weak" ever since the accident to the right, watering at times, and being intolerant of strong light. He could not read with it more than a few minutes at any one time. Vision equalled $\frac{20}{XX}$, but accommodation only $\frac{1}{6}$.

On consultation, it was decided to remove the injured eye; and enucleation was performed. The day after the operation, the accommodation in the remaining eye increased to $\frac{1}{3\frac{1}{2}}$, and four days afterwards he was discharged, this eye being strong and well.

M. J., æt. 37, a miner, eight days before admission to the hospital, was struck in the right eye with a piece of coal, which flew up from the pick with which he was mining. He did not notice any bad effects until about twenty-four hours after the accident, when the eye began to inflame, and became extremely painful. Although treated at his home in Scranton, the eye grew rapidly worse, and at the time of admission it was completely disorganized, an unsightly bulging mass, and so terribly painful that it was necessary to use hypodermic injections of atropia in the temple. The left eye was sympathetically affected, slightly inflamed, intolerant of light, etc. The day after admission, anterior section was performed. In a few hours the sympathetic symptoms in the uninjured eye had entirely disappeared. The man was discharged in ten days, with a good stump, no pain, and no inflammation.

SPASM OF ACCOMMODATION.

Y. R. H., æt. 22, complained of a slight indistinctness of vision, or "mistiness" before his eyes, for distant objects, on looking up from reading, or fine work. He had been troubled in this way for five months, the affection coming on after he had been studying all night for two nights in succession.

Refraction was found to be normal, and accommodation $\frac{1}{4}$ in each eye; there was no insufficiency. He read from choice at about 14″.

Testing him with Snellen's large type, his vision was nearly $\frac{20}{XX}$ for both eyes; but after reading fine print for fifteen minutes, distant vision was reduced to $\frac{20}{L}$. On resting his eyes, however, for a few moments, the former acuteness of vision for distance returned. When allowed to read with a $+\frac{1}{24}$ glass, the change in vision just mentioned did not occur. No latent hypermetropia was revealed by atropia, a strong solution of which was instilled. Iron, quinine, and strychnia were prescribed, and the accommodation was kept at rest by atropia.

INTERSTITIAL KERATITIS.

In a former clinical report of Dr. Harlan's service, the history, condition, and treatment of two typical cases of inherited interstitial keratitis were given; but owing to the patients not returning to the hospital as desired, the results of treatment could not be noted. In the present case, ample opportunity was afforded to record the speedily beneficial effects of specific and local treatment.

L. M., æt. 9, a school-girl, nine weeks before applying for treatment, without any cause known to herself or to her mother, who came with her to the hospital, had begun to be troubled with sore eyes.

Both corneæ over the whole of their surfaces presented a marked "ground-glass" appearance. A commencing vascularity was noticeable at the margin of the left cornea, and a slight vascularity extended half

across the right cornea. Both eyes exhibited episcleral zones.

The history of the patient and her family was interesting, and conclusive as to the origin of the disease. The child's mother had been married twice. She had six children by her first husband, all living and healthy, except one which died in infancy. By her second husband she had also six children, four of whom were still-born; one was living, and apparently healthy, the other was the subject of the present report. Little definite information could be obtained in regard to the second husband, but he was not healthy.

This child had been affected with catarrh of the nasal passages when a baby. Fourteen months before her eyes became sore, she had had an eruption on her scalp. Both tonsils showed signs of ulceration, and the cervical glands were slightly swollen. The teeth were very characteristic, three of the lower incisors having single notches, one having two notches. All the teeth of the upper jaw were irregular and diseased; two of the second incisors were partly through, and both notched. A curious incident occurred in examining the case. On a doubt being expressed as to which were the "second teeth," the mother remarked, "Indeed, doctor, you can easily tell, for her second teeth all have notches."

The child was immediately placed upon the bichloride of mercury, gr. $\frac{1}{48}$, with iodide of potassium gr. iv, three times daily; ten drops of the syrup of the iodide of iron, three times daily, were also prescribed. Locally, a solution of sulphate of atropia, one grain to the ounce, was ordered to be instilled twice daily, and calomel was dusted into the eyes every other day.

In one month, under this treatment, the right cornea was almost clear, and the left was rapidly clearing. In two months there was scarcely a perceptible shade in either eye.

Action of Quinia on the Uterus.—Dr. James Bordley, of Centreville, Md. (*Am. Jour. Med. Sciences*, July, 1872), practising in a region greatly infested by malaria, affirms that the true physiological action of cinchona, so far from producing any uterine contractions, tends directly to control such an action, and to suspend contractions which threaten abortion. Those threatenings which are the result of malarial disturbance are alluded to more particularly. If it be true, as is asserted by some, that cinchona diminishes the proportion of fibrin in the blood and lessens its coagulability, it seems to him a most dangerous remedy to employ for the purpose, even were we to admit that it possesses such emmenagogue power when given in rational quantities.

Dr. O. H. Seeds, of Columbia, Texas, says (*Am. Jour. of the Med. Sci.*, October, 1872), "I have very closely observed the action of quinia on the uterus, and feel convinced that in dysmenorrhœa, amenorrhœa, and other diseases of the uterus resulting from a malarial cachexia, such as occur in this region, the only effect observed from that medicine is that of a stimulant to the organ, tending to restore its healthy function. I have not seen a case of abortion that could be attributed to the action of that remedy."

Dr. S. then mentions the case of a mulatto girl who was seen by him, having taken seventy or eighty grains of quinia to "bring on her sickness," she being four and a half months pregnant. Violent symptoms were induced, but subsided under treatment, and she went her full time, being then safely delivered of a healthy child.

Dr. R. H. Rutland, of Las Animas, Colorado, confirms, in the same number of the *Journal*, the testimony above quoted.

Per contra, Dr. Deneffe reports (*Annales de Gand*, June, 1872) two cases from his own practice, confirming the opinion of Monteverdi and Bouqué on the efficacy of sulphate of quinine as supplementary to ergot of rye.

The first was that of a young lady whose menses had usually been regular, but exposure to cold had suddenly suppressed them at the period immediately preceding her illness. Her period coming on again, the flow was abundant, and soon amounted to a menorrhagia. As she was away from home, a physician was called, who prescribed perchloride of iron, but without effect. On Dr. Deneffe's return he ordered sulphate of quinine, to be taken in 1½ gr. pills every hour; this almost immediately checked the hemorrhage.

The second case was that of a lady whose menses had been suppressed for a time by the influence of violent emotion, but afterwards reappeared with a hemorrhagic character, alarming the patient. She was confined to her bed, and the least movement increased the flow of blood. Sulphate of quinine was ordered, as in the previous case, and, the better to test the power of the drug, she was ordered to rise and walk about. The next day the menses had lost their hemorrhagic character, and on the second day they had ceased entirely. These observations seem to support the theory of Monteverdi and Bouqué that quinine acts as an excitant of the involuntary muscular fibres.

Dr. Josef Hehle (*Wiener Mediz. Presse*, No. 29, July 21, 1872), an Austrian military surgeon, narrates a case of retained placenta expelled by the use of quinine, which occurred in the practice of his friend Dr. Ruziczka. The amount given was twenty-one grains of sulphate of quinia in less than twelve hours. In twenty-four hours from the time of administering the first dose (three grains), the uterus contracted powerfully, and the placenta was expelled. Dr. Hehle says that in such cases the maximum dose should be one scruple. Twelve grains is a medium dose, while six grains will produce in delicate constitutions the menstrual flow, as well as abortion, if the drug is administered at the time that menstruation should occur.

For obstetrical purposes, as for the treatment of periodical fevers, the writer says small doses, repeated frequently, have the greatest effect.

Dr. Ludwig Pollak, of Kaposvar, Hungary (*Wiener Mediz. Presse*, August 18, 1872), says the effect of quinine is seen especially in malarial regions, and that in his own town the common people produce abortion at will by using quinine in large doses, which they procure of the apothecary under the name of "fever-powders."

This effect, however, is exerted by quinine only during the early months of pregnancy, whereas, in the later months, half a drachm per diem may be given with the greatest impunity.

This writer also states that six to eight grains of quinine per diem, in the early months of pregnancy, are sufficient to cure the most severe periodical fever, which in the non-gravid woman would require several scruples of the alkaloid to produce the desired effect.

So far as the expulsive effects of quinine are concerned in the third stage of labor, it may be said that the operation, if a specific one, is very slow, and not to be thought of when speediness of contraction in the fibres of the uterus is demanded.

The *Medical and Surgical Reporter* says that Dr. Felix von Niemeyer's large and valuable library has, since his death, been bought by Albert Moser, of Tübingen, a bookseller, who has carefully catalogued it, classifying it under the same headings as Niemeyer's "Practice." The catalogue contains two hundred pages, and can be obtained from L. W. Schmidt, German bookseller, 24 Barclay Street, New York City.

PHILADELPHIA
MEDICAL TIMES.
A WEEKLY JOURNAL OF
MEDICAL AND SURGICAL SCIENCE.

The Philadelphia Medical Times is an independent journal, devoted to no ends or interests whatever but those common to all who cultivate the science of medicine. Its columns are open to all those who wish to express their views on any subject coming within its legitimate sphere.

We invite contributions, reports of cases, notes and queries, medical news, and whatever may tend to increase the value of our pages.

All communications must bear the name of the sender (whether the name is to be published or not), and should be addressed to Editor Philadelphia Medical Times, care of the Publishers.

PUBLISHED EVERY SATURDAY BY
J. B. LIPPINCOTT & CO.,
715 and 717 Market St., Philadelphia, and 25 Bond St., New York.

SATURDAY, OCTOBER 26, 1872.

EDITORIAL.

SPECIALTIES IN MEDICINE.

IT is not a very long time since it was the general opinion of the profession that a "specialist," if not a quack, was a good imitation of one. Within ten years, indeed, a committee of the American Medical Association solemnly presented to that body a report adverse to the practising of specialties. We have not that report at hand, but we know that it met the approval of many men of great good sense and of no narrow views.

And yet the "inexorable logic of events," the constantly increasing practice and influence of specialties, is, it cannot be denied, settling this question in just the opposite way. A few words will show why this is, and how any tendency to evil in this quarter is to be averted.

In the remoter country districts, in small villages, and even in towns of some size, the "doctor" attends alike to labor-cases, fractures, dentistry, fevers,—all the ailments of the neighborhood. Under this system, one scarcely knows whether to wonder more at the ability and skill which some of these hard-worked brethren develop, or at the needless waste of precious life which the stupidity and ignorance of others do occasionally involve.

As population increases, in larger towns and in cities, and with it the number of physicians, there are certain men who deservedly acquire a reputation for skill in certain cases, and about whom practice crystallizes, as it were, in these special lines. Success in surgery legitimately brings other surgical patients; in midwifery, other obstetric cases; and so on. All this is clear; and now, when we consider the vast advances of modern science, and the wide range of reading necessary to keep pace with the literature of any one branch of practical medicine, is it not obviously for the benefit both of the profession and of the people that each workman should have a chance to thoroughly cultivate a smaller field, rather than to cover more ground less effectively?

We contend that so long as a complete medical education is required of every graduate,—a thorough foundation upon which the study of any special branch may be based,—advantage only can arise from the subsequent partition of the field of labor. Such a system would by no means tend to produce surgeons who could not recognize pneumonia, or physicians who could not detect an ordinary fracture: it would not develop *narrowly*, but *highly* cultivated men. This universality of education is the great safeguard, and will always keep the scientific specialist distinct from the quack.

THE AMERICAN PHARMACEUTICAL ASSOCIATION.

THE twentieth annual meeting of this body was begun in the Central Rink at Cleveland, Ohio, on the 3d of September, and lasted four days. Its proceedings, although not of immediate interest to physicians, will doubtless be of indirect value to the profession at large, affecting, as they will, the progress of so important an auxiliary to medical science.

We note that a proposition for taking the business matters of the Association out of the hands of the members, and placing them in charge of a Council, was not favorably entertained; a motion to indefinitely postpone the subject having been carried without a negative vote.

Another important item was the reading, by Prof. William Procter, Jr., of a communication from the lamented Edward Parrish, on the subject of the preliminary education of young men proposing to qualify themselves for carrying on the drug business, and what preliminary examination, if any, should be required by the colleges of pharmacy. This paper is said to have been "of exceeding interest," and we judge that it took the ground that much higher qualifications should be demanded than at present. A full report of it may be looked for in the proper channels.

The next meeting of the Association will be held in Richmond, Virginia, beginning September 18, 1873.

DENTAL COLLEGES.

THE Philadelphia Dental College will begin its winter session of lectures on the 1st of November. Dr. J. H. McQuillen, 2100 Arch Street, is the Dean of the Faculty.

The winter session of the Pennsylvania College of Dental Surgery will open at the same time. The Dean of its Faculty is Dr. E. Wildman, 1205 Arch Street.

CORRESPONDENCE.

PENNSYLVANIA LAW AS TO LUNATICS.

To the Editor of the Philadelphia Medical Times:

DEAR SIR:—The provisions of the law of Pennsylvania regulating the admission of insane persons into hospitals for the insane seem to be sufficiently guarded, if properly carried out by those to whom its execution is committed, to secure all the rights of the citizens, and to prevent fraud or injustice. The section reads thus:—"Insane persons may be placed in a hospital for the insane by their legal guardians, or by their relatives or friends in case they have no guardians, but never without the certificate of two or more respectable physicians, after a personal examination made within one week of the date thereof; and this certificate to be duly acknowledged and sworn to or affirmed before some magistrate or judicial officer, who shall certify to the genuineness of the signature and to the respectability of the signers."

If the physicians who are called upon to examine a person alleged to be insane are careful to make that examination as they would in any other medical case in which they felt that their skill and reputation were involved, there can be no likelihood of injustice in any ordinary case. It is true, there are cases where the subject may be involved in doubt and uncertainty; but such only require the greater caution and calmer judgment on the part of the physician.

Let the physician bear in mind one or two plain, practical ideas, and he will rarely fail to arrive at a correct conclusion. Let him remember that insanity is a disease, not some metaphysical entity; to be treated as other diseases are treated, carefully, judiciously, and after a full investigation into the case. Let him be particular to make diligent inquiry into the patient's previous history, character, modes of thought and expression, conduct, and mode of life; ascertain whether any predisposition to insanity or other kindred nervous diseases exists in the family; compare the condition of the person at the time of the examination with his previous character, conduct, and mode of life, so far as these can, after diligent inquiry, be ascertained; examine also, carefully, the physical symptoms, and the condition of the different organs of the body; and, where any uncertainty may exist, repeat the examination once or twice. Never trust entirely to the statements of others, but compare them with his own observation, and use these statements as guides or assistants in the investigation. Never judge of the mental disorder of any one by any imaginary standard, but compare each patient with himself as he may have been at an antecedent date; and as the physician is ordinarily the family physician, or has resided in the community where the patient resides, he can readily ascertain all that need be known in regard to him; or should he be a stranger, he can obtain from the friends, relatives, or neighbors, such information as will materially aid him in coming to a proper conclusion.

Having made the examination with the required care and attention, it is requisite that the certificate be sworn to before some magistrate or judicial officer; and the provisions of the law requiring this certificate to the genuineness of the signatures and the respectability of the signers, would seem to obviate any objection which might be raised as to improper certificates or signatures. It is absolutely necessary that the process for procuring the certificates and the admission of patients into the hospitals for the insane be as plain and free from technicality and expense as possible, and all unnecessary publication of the fact of the mental disorder of any member of a family should be prevented, out of respect to the feelings of the person himself, as well as of the relatives and friends. People dislike to be obliged to submit to much expense or trouble in procuring the certificates, and most have a great dread of publicity; and the law has wisely considered these points in making the mode of procedure as free from expense and technicality as possible.

I am, Sir, yours respectfully,

JOHN CURWEN.

Pennsylvania State Lunatic Hospital,
Harrisburg, October, 1872.

PROCEEDINGS OF SOCIETIES.

PHILADELPHIA COUNTY MEDICAL SOCIETY.

AT a conversational meeting of the society, held Wednesday, October 9, 1872, at 8 o'clock P.M., Dr. J. G. STETLER, VICE-PRESIDENT, in the chair,

Dr. WILLIAM GOODELL exhibited a vectis which he had used for many years and had found very efficient. It had a broad blade, a wide fenestra, and a very convenient wooden handle provided with a joint, so that it could be folded up into a very small compass. He compared it with the one usually sold in the shops, which is too short, too painful to the grasp, and too slightly curved, to be very serviceable. He considered it a very valuable instrument, but not to be compared to the forceps in the range of its applicability. That there were, however, cases to which the former was better suited,—for instance, in imperfect flexion of the head, as in transverse cranial positions; and in cases in which the forceps cannot be applied in the occipito-mental diameter, such as in mento-posterior positions, and in presentations of the brow or sinciput. It should also be used in those cases of occipito-posterior positions of the vertex in which the forceps cannot be applied to the

sides of the child's head, but only obliquely. He wished to correct one misconception with regard to the utility of this instrument. The vectis had been vaunted as very efficient in converting a face-presentation into one of the vertex, but he had never succeeded in doing this by any other instrument than the hand. The vertex was in this presentation so high up in the pelvis,—in fact, in the cavity of the abdomen,—that the instrument would almost disappear in the genital passages, whilst the intervening vault of the cranium prevented such an adjustment as the admission of the occipital protuberance into the fenestra. The cases in which he applied the vectis most frequently, were those in which the head would not engage; those in which there was delay at the outlet; those in which the pains were insufficient; those in which the head did not press firmly enough upon the perineum; and especially those in which the woman was so nervous and excitable that he knew she would obstinately object to the forceps, or else put off their application until she and her attendants were completely worn out. In such cases he had time and again applied the vectis without the knowledge of the patient or of her friends. He further stated that the vectis might be applied to any part of the head where the indications pointed; but that in the majority of cases the place of application will be the sub-occipital region, and he then aimed to slip the fenestra over the occipital protuberance. Whenever thus adjusted, very forcible traction could be safely made, but it should always be made in the direction of the handle. When the exigencies of the case demand that the blade be passed over the cheek or brow, very little force should be exerted, lest the soft parts of the child should sustain injury. Finally, in view of these facts, it was always most important to make a careful diagnosis of the position of the head, lest the instrument should be unwittingly placed where it could do harm.

Dr. W. M. Welch asked what success Dr. Goodell had met with in forcing with the forceps an anterior rotation of the vertex presenting posteriorly in primiparæ.

Dr. Goodell replied that in these cases he never began to force rotation until the vertex was pushing back the coccyx, or was well out of the outlet and pressing upon the perineum. That the great secret of securing anterior rotation in these cases lay in the application of the forceps to the sides of the child's head, and not to the right brow and left occipital region, as usually made, which tended to induce rotation into the hollow of the sacrum. That by observing this rule, and with the aid of the vectis, he had thus far succeeded in delivering every head but one anteriorly.

Dr. William T. Taylor asked what necessity there was for anterior rotation if the head had been brought down so low as to bulge out the perineum; for was it not then out of the outlet, and ready to be delivered?

To this question Dr. Goodell replied, that in an occipito-posterior position the vertex began to press upon the perineum long before the head was out of the outlet; indeed, it was hardly free from the inferior strait until the very moment of delivery. That an anterior rotation, by changing the mechanism of delivery from flexion to extension, was expedient not only in order to shorten labor, but also to save the perineum from excessive distention and consequent injury.

Dr. R. Burns had always used the forceps and never the vectis, but he was now satisfied that the latter instrument could be made very useful.

Dr. J. S. Eshleman had no experience with the vectis, although he frequently resorted to the use of the forceps. He had been deterred from using the former instrument on account of its faulty form, but he was convinced that the one Dr. Goodell had exhibited was capable of exerting great traction-power.

Mr. Curt W. Meyer, of New York, presented a new continuous galvanic-current battery, and stated that the following are the merits he claims for it over others:

1. Sufficient power for a continuous galvanic current for any case in galvano-therapeutics, provided an adequate number of elements are employed.
2. Durability of the current and of the battery.
3. Its simplified construction, rendering it easily handled and portable.
4. Freedom from acid vapors or corrosive action.

The solution employed is a saturated solution of the chloride of ammonium, with gas coke and zinc in large-sized test-tubes, with a platinum connection at the bottom, which penetrates into the coke and is clamped into the base of the battery, making the positive connection.

Dr. Turnbull thought that Meyer's battery had great advantages in being portable, clean, and free from unpleasant odor in operation; also in producing so little pain or nervous shock. A current of moderate intensity was productive of the best results.

REVIEWS AND BOOK NOTICES.

The Evolution of Life. By Henry C. Chapman, M.D., Member of the Academy of Natural Sciences, Philadelphia. J. B. Lippincott & Co., 1863.

This handsome volume will, no doubt, be cast aside by many timid people whose reverence for the Mosaic account of the creation, as interpreted by the monks of the dark ages, impels them to look with suspicious eyes upon all such researches into the events of prehistoric times. But there is a large, and we are happy to say a constantly increasing, body of thoughtful readers, who, to paraphrase the words of a distinguished living divine, believe that the same old battle fought by the theologians of the seventeenth century with Galileo's astronomy, and by those of the eighteenth with Hugh Miller's geology, is now being waged with Darwin and Spencer's anthropology; and foresee for it a like ill success. Inquirers of this enlightened class hold a faith in Omnipotence too profound and steadfast to admit the fear that any mere human, and therefore finite, search after truth, can shake His throne in the Infinite. They possess a grasp of intellect broad enough to perceive that, even should science demonstrate that the result of the primeval fiat was the "derivative creation" of evolution instead of the "special creation" of rabbinical and monkish tradition, our grand argument for the wisdom and goodness of the Almighty, from the countless evidences of design in the structure and adaptations of his creatures, would be only strengthened and reinforced. Among such unprejudiced students of nature we feel sure this book will be warmly welcomed as a clear, perspicuous compend of the latest investigations and conclusions in regard to the evolution of life upon our planet. The author traces the development of organized beings from the lowest of the protozoa, the Monera of Häckel, through the vegetal amœbæ on one hand, to the giants of the vegetable kingdom; and from the amœbæ on the other, up a gradual ascent to man, the highest, that is, the most specialized, type of the vertebrates. His endeavor has been "to place before the reader in as popular a manner as possible, the most important generalizations in reference to the structure of plants and animals, their petrified remains and mode of development; and to point out how the theory of the evolution of life follows from the facts of anatomy, geology, and embryology." The

work is well printed on fine paper, and profusely illustrated with figures and charts, which largely contribute to the value of many rather brief descriptions in the text. It is comparatively free from typographical errors and those of inadvertence, although (without desiring to be hypercritical) we must confess to some surprise at finding that Dr. Chapman informs his readers, on page 36, that trichiniasis is "a disease resembling typhoid fever and acute rheumatism," albeit some symptoms are analogous in these complaints. An elaborate map, exhibiting a hypothetical sketch of the origin and diffusion of mankind, is prefixed to the volume, and possesses great interest from an ethnological point of view.

THE PRESIDENT'S ADDRESS BEFORE THE SOUTH CAROLINA MEDICAL ASSOCIATION, AT THE MEETING HELD IN COLUMBIA, April, 1872.

Dr. Porcher's address consists principally of remarks upon the treatment of yellow fever, and the great success attendant upon his efforts.

After dissenting in very strong terms from Dr. Thomas King Chambers's ideas as expressed in "Restorative Medicine," and asserting that it is *not "by endowing or enriching the body" that cures are effected in this disease*, he bows in *action* to the same idea of Dr. Chambers by giving a large dose of quinia at the start, and following up his treatment by various saline remedies, which are calculated to prevent waste and oxidation of the tissues. With the large dose of quinia (gr. xxiv), he gives also a large dose of calomel (gr. xx), and terms his treatment "*spoliative*." . . . A few lines farther on, he virtually acknowledges that his medication is not spoliative, as "*purgatives are on no account* to be persevered in."

Our author does not seem to have yellow fever as an entity very well defined in his own mind, for we find him expressing himself in this peculiar manner: "*Yellow fever differs from paludal, malarial fevers in the marked absence of decided periodicity; and in all its phenomena and its manifestations it is nearest to the so-called bilious-remittent fever of hot countries. But it is much more intense and violent; albumen escapes much oftener from the congested kidneys, and it is characterized by the frequent occurrence of black vomit. In a fever like this of one paroxysm.*" . . . A few lines farther on, he speaks of the "*congested and engorged liver*" of yellow fever.

Now, we as critics would say that Dr. Francis Peyre Porcher's treatment of yellow fever is as nearly *restorative* as he can make it, and although he does not give "*cod-liver oil, beef-tea, or even stimulants*," he still fulfils Dr. Chambers's requirements in using quinia, calomel, saline purgatives, and diuretics and cold applications to the surface; for in these he employs the means to stop waste, which accomplishes the same end by a better way than the supply of new materials, which could not be assimilated.

Again, we must say that on careful examination we do not see any close resemblance between yellow fever and bilious-remittent fever, nor do we think that albuminuria ever occurs in the latter, while the congested and engorged liver is peculiar to it, and the liver of yellow fever is so notably pale and anæmic that for many years it was considered to have undergone rapid fatty degeneration. It is also a notable fact that its secretion is stopped, no bile being present in the matters vomited after the stomach and duodenum have been emptied in the early stages of that process.

Lastly, we would say that it does not sound well to speak at the present time of disgorging the liver by means of a mercurial purgative.

Aside from the faults to which we have alluded, the address is pleasing and instructive, and filled with good advice and the results of watchful experience, and if it were not for its somewhat pretentious and faulty physiology and verbal pyrotechnics, we would have nothing but praise to award.

THE PRINCIPLES AND PRACTICE OF SURGERY. By FRANK HASTINGS HAMILTON, A.M., M.D., LL.D., Professor of Surgery in Bellevue Hospital Medical College, etc. etc. Illustrated with 467 Engravings on Wood. 8vo, pp. 943. New York, William Wood & Co., 1872.

We do not want to damn this handsome book with faint praise, but we cannot think it will take such a place among treatises on general surgery as its author's work on "Fractures and Dislocations" took among works on that branch of the subject. Dr. Hamilton is an excellent surgeon, of wide experience and sound views, and we believe he is a popular and interesting lecturer; and yet, in our opinion, his present effort will hardly supplant other text-books of like scope, except with his own classes.

Our space does not admit of an analytical review, especially as the plan adopted by our author has no marked peculiarity: we can, therefore, only mention a few points in proof of the opinion above expressed. While only forty pages are devoted to the eye, and but thirty to the whole subject of venereal diseases, a chapter is introduced, of only eight pages indeed, on the anatomy, development, and surgery of the teeth,—a topic to which justice cannot be done within such narrow limits. The chapter on "Tumors" is unsatisfactory, mainly in the matter of the diagnosis. The directions for the ligation of special arteries are meagre in the extreme. Only one operation for hare-lip is described, and that the old one, by straight incisions.

We will not dwell on minor matters, such as misspelt names ("Ashurst" for "Ashhurst," "McLeod" for "Macleod"); but "tolliter effectus" is not Latin, nor is "processus dentata."

Let us be distinctly understood. Our criticism is not so much that we find faults, as that we do not find superiority. We do not think the book does its able author justice.

BOOKS AND PAMPHLETS RECEIVED.

A Manual of the Diseases of the Eye. By C. Macnamara, Surgeon to the Chandnie, and the Ophthalmic Hospital, Calcutta, etc. Second Edition. 16mo, pp. 620. Philadelphia, Lindsay & Blakiston, 1872.

A Year of Experiment in Electro-Therapeutics, etc. By George M. Beard, M.D., and A. D. Rockwell, M.D. Reprinted from *The American Practitioner*, August, 1872. 8vo, pp. 18. Louisville, John Martin & Co., 1872.

Medico-Legal Science. By Thaddeus M. Stevens, M.D. Reprinted from the Transactions of the Indiana State Medical Association. Indianapolis, 1872.

Normal Ovariotomy. By Robert Battey, M.D., Rome, Georgia. Reprint from the *Atlanta Medical and Surgical Journal*, September, 1872. 8vo, pp. 18.

On the Physiology of Syphilitic Infection, as applied to the Successive Manifestations of Disease. By Fessenden N. Otis, M.D., etc. Reprinted from the *N. Y. Medical Journal*, July, 1872. 8vo, pp. 28.

Transactions of the American Medical Association, vol. xxiii. 8vo, pp. 757 (with an Appendix on the Nomenclature of Diseases, pp. 94). Philadelphia, 1872.

GLEANINGS FROM OUR EXCHANGES.

Symptoms produced by the Presence of a Needle in the Thoracic Parietes (*Le Mouvement Médical*, August 10, 1872).—M. Pozzi reported to the Société Anatomique, on the 2d of August, the case of a girl, who, at 13 years of age, had a needle thrust into the fifth intercostal space on the left side. From this time, hyperæsthesia of the skin of this region, with pains in the arm and shoulder, prevented her lifting the left arm, and hindered other movements. At 17 years of age, an attempt at extraction by manipulation was followed by irritation and swelling of the skin. At the end of nine years, the pains persisting, the girl came to the clinical hospital to get the foreign body extracted, feeling it beneath the skin. M. Polaillon made an incision, and drew out a part only of the needle, which broke off, having become oxidized. M. Pozzi thought it better in such cases to dissect out the offending body.

Curious Malformation.—M. P. Budin (*Le Mouvement Médical*, August 17, 1872) recently brought before the Société Anatomique a heart, from a case in which the skull and genital organs were likewise malformed.

The organ, in the thoracic cavity, looked larger than normal just after birth. There was but one artery, coming off from the base of the ventricles, and representing at once the aorta and pulmonary artery; this vessel, arising by two branches, one from each ventricle, described a curve like that of the aortic arch. It presented three sigmoid valves, and gave off the two coronary arteries, two large branches, going one to the right and one to the left lung, the innominate, left carotid, and left subclavian, and then descended along the vertebral column in the usual way.

There was, therefore, no ductus arteriosus in this child. The right auricle was very large, the left very small, but elongated, as if contracted upon itself. The inter-auricular septum was also absent, being merely represented by two very thin filaments, extending from the anterior to the posterior auricular wall. There was, therefore, no foramen of Botal, and, as the left auricle was scarcely at all developed, the right auricle seemed to communicate with the left almost as freely as with the right ventricle. The two auriculo-ventricular valves were otherwise normal.

As to the vessels carrying blood to the auricles, there were found the venæ cavæ, superior and inferior, and a coronary vein opening into the right one; but there was no pulmonary vein, the blood coming from the lungs flowing into the vena cava superior.

To sum up, there was in this heart a very large right auricle opening into both ventricles,—a communication between the two ventricular cavities,—a single arterial trunk representing the aorta and pulmonary artery,—no pulmonary veins,—no foramen of Botal,—no ductus arteriosus.

Experiments on the Production of Crepitant Rales.—MM. Cornil and Grancher (*Le Mouvement Médical*, August 10, 1872) reported to the Société de Biologie, at its meeting on July 20, that they had made some experiments on this point, as follows: Having laid open the trachea of a cadaver, and introduced a tube by which to make artificial respiration, they ausculted the lung, first through the thoracic walls, and afterwards, the lung being laid bare, with the stethoscope. In the former case they heard a sound analogous to the vesicular murmur, but slightly exaggerated; in the latter they heard a sound like the crepitant râle of pneumonia, although the lung experimented on was a healthy one.

This experiment, repeated under various conditions, gave the same results: thus, in the body of a man in whom during life crepitant râles had been heard, and who was believed to have had pneumonia, the investigators heard, proceeding as above described, crepitant râles, and on examination the lungs showed foci of pulmonary apoplexy. The same happened in a case of pneumonia of the apex. The same also, when, having injected tallow into a part of the lung, they ausculted when the tallow had solidified.

MM. Cornil and Grancher have drawn the following conclusions from this first series of experiments:

1. The phenomena of auscultation can be reproduced in the cadaver by inflating the lungs through the air-passages. 2. The crepitant râle is not produced in the hepatized portion of lung. 3. It occurs in the alveoli adjoining the indurated mass. 4. The crepitant râle occurring in puffs in inspiration is identical with that which is obtained on listening directly to the normal lung. 5. One can obtain it artificially by transforming a portion of the lung into a hard mass, impermeable by air, as, for instance, by the injection of tallow. The same result is arrived at by the interposition of a resistant body between the lobes, such as a piece of wood, by a cord placed on the tip of a lobe, etc. 6. The hepatized part transmits the crepitant râle readily, in spite of a layer of false membrane or even of liquid.

These researches were criticised by several other members. M. Lépine reminded the Society that M. Petrequin had previously experimented in auscultation on the dead body.

On the Pulvis Glycyrrhizæ Compositus, a Laxative Preparation of the Prussian Pharmacopœia.—David Page, M.B., of Kirby-Lonsdale, England, says:

"For the treatment of simple constipation resulting from atony of the bowel, the compound liquorice powder is admirably adapted. Whether in simple uncomplicated torpor of the intestines, or in constipation accompanying temporary gastric disorder, the powder, alone or as an auxiliary to appropriate remedies, is preferable to other preparations of its class. In the former, our object is rather to call into play the peristaltic action of the intestine, than to deplete by serous transudation from its walls, and, in the latter especially, no prudent practitioner would run the risk of aggravating the disordered stomach by the exhibition of purgatives possessed of irritant or drastic properties. The compound liquorice powder is composed of the following constituents, so prepared as to form when incorporated an almost impalpable powder:

℞ Senna leaves, ℥vj;
Liquorice root, ℥vj;
Fennel seeds, ℥iij;
Sulphur, ℥iij;
Refined sugar, ℥xviij.

"This formula is given in the Pharmacopœia Borussica.

"The active ingredients are sulphur and senna. The action of the former, when administered alone, is frequently accompanied by tormina, and its continued use is apt to cause derangement of the mucous membrane of the upper intestine. The physiological action of sulphur appears to be upon the muscular coat, and less upon the mucous surface, while senna is a more active purgative, more apt to excite tormina, and acts more upon the mucous than the muscular coat. By the aromatic and stimulant properties of the fennel, and the demulcent action of the liquorice, itself a mild laxative, the effects of the more active constituents are judiciously modified.

"The usual dose is a small teaspoonful at bedtime in water, with which it is easily mixable, forming an agreeable draught. Children, to whom Gregory's powder is

a terror, readily take it with a belief that it is a sweetmeat.

"That the action of the powder is not to produce catharsis with serous transudation is proved by the motions, which are usually well formed and soft."

THE MECCA PILGRIMS AND THE CHOLERA (*Wiener Mediz. Presse*, July 14, 1872).—In the present year the pilgrimage did not occur in the summer months, which fact alone was favorable to the health of the masses assembled in the East. The great precautions, however, exercised by the English, Dutch, and Egyptian governments, in regard to the transportation and hygiene of the pilgrims, prevented the appearance of cholera. Dr. Pasquier, health officer at Dschidda, in his report, states that the number of pilgrims present at the festival on Mount Arisat was estimated to be about 110,000. 30,058 of these arrived at Dschidda in thirty-seven steam-vessels, thirteen three-masted sailing-ships, and by means of small Arabian barges; 10,531 came from the Indian Ocean, viz.: 6205 Malays, hailing from Singapore and Java; 4326 from the continent of India, hailing from Bombay and Calcutta; 2040 from the Persian Gulf; 2126 from the Arabian, and 2507 from the African, coast of the Red Sea; 11,516 came by the way of the Suez Canal; 10,000 from Algiers and Tunis; 1200 from Caucasus, and 316 Egyptians. About 80,000 came with caravans from Egypt, Syria, and chiefly from Medschid and other places in Central Arabia. According to Dr. Kadri Effendi, health officer at Mecca, such a concourse of Bedouins has rarely, if ever, occurred. Dr. Pasquier congratulates himself that no case of cholera occurred upon the pilgrims' ships, and that no trace of an epidemic showed itself during the festival, which fact was favored by good weather and mild temperature. Dr. Aref Bey, Vice-President of the Chief Sanitary Commission in Constantinople, was present in Mecca during the entire festival, in order to carry out all the sanitary regulations adopted for the occasion. In this work he was nobly sustained by Drs. Server Bey, Raef Effendi, and Kadri Effendi. We need not dwell upon the great obligations conferred upon all Europe by the strenuous endeavors of these men to prevent an outbreak of the cholera in the ranks of the pilgrims.

"NEURALGIA OF THE TESTICLE" (*Wiener Mediz. Presse*, July 28, 1872).—Dr. I. Lazarus, of Czernowitz, several years ago wrote an article on spermatorrhœa, in which he stated that sometimes neuralgia of the testicle was an attendant upon spermatorrhœa. Since then he has had ample opportunities for observing this fact in private and hospital practice.

In most cases, only a portion of the testicle is implicated, and this is usually the epididymis, in which the head and the initial portion of the vas deferens are involved.

The left testicle is more apt to be affected than the right. Anatomical changes have never been observed by the author, although the painful affection may have continued for many years.

Some observers have described a swelling at the junction of the epididymis and vas deferens, and a slight dilation of the blood-vessels at that point, as changes consequent upon the neuralgic affection. Neuralgia of the testicle has, however, special causes. In a very large number of cases, sexual abstinence is the cause of intense neuralgia of the epididymis. This predisposing cause is not the lot of those only who observe voluntary celibacy, but is very much more frequently brought on by abstinence caused by weakened sexual power or temporary impotency. In such cases, if no involuntary emissions occur to relieve the congested vessels and distended seminal canals, neuralgia of the testicle shows a special tendency to develop itself.

Such a condition of the nerves is instantly relieved by a partial act of coitus or an imperfect nocturnal emission.

In many cases the neuralgia of the testicle is caused by dyspepsia occurring in nervous, badly-nourished individuals, and in these cases shows no disposition to disappear. Protracted inflammation of the epididymis, accompanied by induration; strong injections in gonorrhœa; and the passage of renal calculi through the ureters, may be causes of protracted neuralgic affection of the testicle.

A very remarkable instance of neuralgia of the testicle occurring in a man who had fallen from a scaffold, and who suffered from paralysis of the inferior extremities, is given by the author. The reason assigned for the neuralgia, as well as for the paralysis, was a central lesion in the nervous apparatus.

Neuralgia of the testicle has two other causes in varicocele and spermatorrhœa. The first symptoms are a painful sensibility in the head of the epididymis, which continues without intermission for some time, closely resembling the symptoms of inflammation of the epididymis. This, however, is never attended by any swelling or redness, and in a few days gives way to a paroxysmal and boring pain. In such cases, motion and cold are provocative of intense pain, while heat and perspiration greatly relieve the suffering. Erections may provoke so much pain in the testicle as to cause nausea and vomiting.

The treatment consists in the removal of impotence and of intercurrent inflammations, as well as of spermatorrhœa and dyspepsia. When the discontinuance of continence is impossible, the author has found great benefit from the use of sulphate of zinc, internally and locally, by hypodermic injection.

In the former instance,—

℞ Zinci sulphat., gr. iij;
Aq. destillat., f℥v;
" laurocerasi, f℥j;
Syr. aurant. cort., f℥ss.

S.—Dessertspoonful three times daily.

For hypodermic injection,—

℞ Zinci sulph., gr. j;
Aq. destillat., f℥iij–iv.

S.—Inject a half-syringeful into the posterior wall of the epididymis, once daily.

IDIOPATHIC HYDROPHOBIA.—The *Chicago Medical Examiner* of July 15 contains the report of a case of hydrophobia, in which there was no known evidence of inoculation or poisoning. The patient was admitted to Mercy Hospital, January 24, 1872, at 12 M., and died the following morning, at seven o'clock. He was aged twenty-eight years, of medium size, rather robust in appearance, and had been employed as an engineer. For two nights previous to his attack he had been at parties nearly all the nights, engaged in dancing and the excitement usual on such occasions, and yet attending to his work during the day. Neither himself nor friends had any recollection of his having ever been bitten by dog or cat, or any animal that could have been rabid. He had formerly practised masturbation freely. About ten days previously he had been vaccinated, which had produced a large sore on the arm, still in active progress at the time of his admission. The following are the remarks upon the case by Prof. N. S. Davis:

"The patient was seen by two or three intelligent physicians before he was brought to the hospital, and by several members of our college faculty, including Professor Andrews, while here, and all agree that the symptoms throughout were well-marked hydrophobia. It is reasonably certain, however, that they were not induced by the bite of any rabid animal. Was there some peculiar animal poison absorbed from the large

and unhealthy vaccine sore on his arm? Or did the excitement of dancing-parties at night and work during the day, co-operating with the disturbing influence of the vaccine virus, establish the irritation of the nervous centres on which the violent symptoms depended? Can hydrophobia be induced without the agency of a specific virus derived from a rabid animal? These are interesting questions suggested by the case under consideration, but which are not easily answered. Some have claimed that hydrophobia is simply a peculiar affection of the cerebro-spinal nervous centres, and have expressed doubts about the existence of any such poison as rabies. The facts pointing to the existence and destructive influence of such a poison are too numerous, however, to admit of reasonable doubt. And yet we are compelled to admit that cases presenting all the phenomena of hydrophobia have occurred that could not be traced to the introduction of any such poison. Such is, indeed, the case before us."

A Case of Chronic Polyuria (*Wiener Mediz. Presse*, August 18, 1872).—Prof. Loebel, of Vienna, gives the following history of a case of polyuria in a lad fifteen years old, who has been obliged for some time past to "urinate very frequently." He was admitted to the ward under the charge of Prof. Loebel, and during his sojourn there, nothing abnormal, save the excessive urination, was observed. On the day of his reception, he passed 9000 cubic cm. of urine.

The largest amount passed on any one day was 16,000 cubic cm.

The usual quantity amounted to 10,000 to 12,000 cubic cm. The color of the urine was very pale, and the sp. gr. was 1.002, or about that of ordinary spring-water. Once it reached 1.006, and once it amounted to 1.007. The picrometer was frequently used, since the urinometer of Haller is not applicable to such cases of alteration in the specific gravity.

The urinometer sank below 0, which was quite unexpected, since the urine, though very dilute, contained all the constituents of normal urine, and, therefore, should have had a specific gravity greater than that of distilled water. The reaction was usually acid, though once it was neutral. The amount of urea was found to be relatively decreased, but the entire amount was found to be normal, viz., 24–30 gr. per diem.

The boy's appetite was excellent, and his nutrition good. His weight increased while in the hospital.

All treatment of this case was fruitless.

For several days in succession, three to four hours daily, the boy was packed in warm-water cloths, but the skin remained dry, and the amount of urine showed no changes. Then opium was given, $\frac{1}{4}$ gr. daily; subsequently this was increased to $\frac{3}{4}$ gr. daily, without the slightest effect upon the diuresis. This treatment was discontinued, since the patient lost his appetite and suffered from headache.

Fowler's solution, ten drops daily, succeeded the foregoing remedies, but had no effect upon the amount of urine excreted. The patient suffered at one time from a severe diarrhœa, lasting several days, during which attack the amount of urine was not in the least diminished.

The observation of this case lasted from January 6 to April 10, at which time the patient left the hospital.

Two Cases of Cysticercus cellulosæ in the Human Eye (Dr. J. Hirschberg, of Berlin, *Virchow's Archives*, vol. liv. Parts 1 and 2).—In one case the worm was in the deep portion of the vitreous humor, in the other it was in the anterior chamber of the eye. After the worm had been detected by means of the ophthalmoscope, an incision was made in the sclerotic, as for the extraction of a cataract; then iridectomy was performed, and the crystalline lens was slowly and completely extracted while the patient was still in the horizontal position.

The upright position was then assumed, and a small hook was inserted into the vitreous body, and the entozoon dragged forward till it was visible to the unaided eye. By causing the patient to bend forward, the edges of the sclerotic wound were made to gape, and the worm slipped out upon the table. The wound healed by first intention, and the form of the eyeball has been completely retained.

The second case is important, since it demonstrates that the position of the parasite may be mistaken for one in the lamellæ of the cornea, when in reality it is in the anterior chamber of the eye. Both parasite and patient were very young: the former about twelve weeks, and the latter two years. An incision was made in the inferior portion of the cornea, and the cysticercus extracted head-foremost.

Gentle pressure and instillation of atropine caused the wound to heal in two days. The eye showed no irritability, and the sight remains to-day perfectly normal.

Feeding by the Rectum.—With reference to the use of the pancreas of animals in the formation of nutrient enemata, a further communication on the subject, by Dr. Leube, appears in the *Centralblatt für Medizin. Wissenschaft.* (July 20). He says that the plan of obtaining the pancreas in the ordinary way from the butcher succeeds very well in the autumn and winter. In the warmth of summer, however, the gland very soon begins to undergo decomposition, and in consequence loses its digestive power, and becomes irritating to the intestine, producing rapid expulsion of the material injected. These mishaps may be easily avoided by making a glycerin extract of the pancreas. This extract is quite equal in digestive power to the fresh pancreas, and will remain good for several weeks. Dr. Merkel, of Nuremberg, has made several trials of this modification, especially in a case of iodine-poisoning; and the results have been equally favorable with those following the use of the pancreas itself. He describes the following as the best mode of making the pancreatic injection. The pancreas of a bullock (which is sufficient for three enemata) is finely chopped, and rubbed with 250 grammes of glycerin; and to each third of this, when about to be used, are added from 120 to 150 grammes of finely-divided meat. This mass is digested in the bowel as completely as the meat and pancreas mixture already described. It is important that the mixture of pancreas and glycerin with meat should be injected into the rectum as soon as it is made; for, if it be allowed to stand, the meat swells up, and the injection is thereby rendered difficult.

Tea Threatened with Competition.—A foreign journal states that tea and coffee are threatened with a Brazilian rival called "guarana," which consists of a tree known to botanists as the *Paullina sorbilis*, which is very abundant. The tree produces a fruit about the size of a walnut, containing five or six seeds, which are roasted, mixed with water, and dried. Before being used they require grinding, when they fall into a kind of powder. The active principle is an alkaloid identical with that found in tea or coffee, but there is twice as much of it as there is in tea. Guarana is now largely sold by druggists in the form of powder, which is a rapid specific for sick-headache. Indeed, we know of nothing equal to it in efficacy when taken at the beginning of an attack; but as to its being a competitor to the old-fashioned tea, we imagine that it will take a long time yet to find anything like a substitute.

Guarana in Sick-Headache (*Dublin Journal of Med. Science*, August, 1872).—Dr. Wilks (*Brit. Med.*

Journ., April 20, 1872) calls attention to the use of this drug as so encouraging in the treatment of sick-headache, and asks for further information. His attention was called to it about two years since, by Mr. Helmcken, of British Columbia, and more recently by Dr. Wood, of Montreal.

Guarana, or Paullinia, is a paste prepared from the seeds of a Brazilian plant, *Paullinia sorbilis*, in a manner somewhat similar to chocolate. It possesses a peculiar odor, a bitter astringent taste, and contains no inconsiderable amount of caffein. A full account of its properties and uses will be found in Guibert's *Nouveaux Médicaments*, second edit., p. 17.

Bromide of Potassium in Traumatic Tetanus.—Dr. Cephas L. Bard reports, in the *Western Lancet* for July, 1872, a case of traumatic tetanus in a girl 15 years of age, successfully treated by the removal of a foreign body, a piece of bone, from the sole of the foot, and by bromide of potassium given in thirty-grain doses every hour. Four doses produced a marked improvement, and complete recovery ensued.

MISCELLANY.

Poisoning by Cyanide of Potassium taken in Mistake for Medicine.—An English paper says, "On Tuesday, June 25, an inquest was held at the Queen's Head, Chelsea, respecting the death of Mr. John King. Deceased, who was under medical treatment, had his medicine-bottle in the bar, and on taking a dose became suddenly faint and died in two hours. It was then found that some cyanide of potassium had been put into an empty medicine-bottle, and the label, 'To be taken every four hours,' left upon it. Edward Jennings, potman to deceased, said he had been in the habit of obtaining two-pennyworth of cyanide of potassium about once a month, from Mr. Pasmore, chemist, for Mr. Edward King, who used it for cleaning the metal-work of the refrigerator in the bar. The mixture, up till Tuesday in the previous week, always used to be made and kept in a very old dirty bottle, but the regular bottle was then broken. Mr. Edward King, being asked by the coronor how the cyanide of potassium came into the medicine-bottle, said, 'I put it into that when the other bottle was broken last week. It was a fresh lot that I made up. I took it out of the locker about a quarter after six in the morning, and put it on the shelf to clean the refrigerator with, when it got cool after breakfast. My father must have come in and put his medicine-bottle by the side of that, and then taken up the poison-bottle in a mistake, but he always knew that we used the cyanide of potassium three times a week, and always on a Saturday.' The jury returned a verdict of accidental death."

[Such accidents can always occur anywhere, if poisons are sold without unmistakable warning, either in the character of the bottle or in the label, of their nature. Precautions of this kind ought to be prescribed by law, and a suitable penalty duly enforced for their neglect.—Ed.]

Doctors' Bills.—Dr. St. John Roosa, in his Anniversary Address to the Alumni of the Medical Department of the University of the City of New York, tells the following good stories:

"There are several anecdotes floating about our city, relative to the subject of fees, which may or may not be true, but which, after all, illustrate the paternal relations existing between tried and trusted medical advisers and their patients, such as obtained in the times when people did not change their physicians as readily as they would a garment.

"It is said that the late Dr. F., for so many years the chief attraction of many circles of our society, once sent in his annual bill, which was about as large as usual, for medical services rendered the family of one of his most valued friends, when, in point of fact, he had not been in the house professionally during the entire year. The bill was paid as usual, but when the head of the family met Dr. F., he remarked, 'Doctor, I got your bill the other day, but I don't remember that any of us have been sick this year.' 'Very likely not,' answered the bluff man of science; 'but I stopped several times at the area gate, and inquired of the servants how you all were.' For that year, at least, the good man was paid on the Chinese principle.

"The late Dr. S., who was for many years one of the prominent medical men in New York, is said to have once sent in a bill for three hundred and forty-two dollars and ninety-two cents, or some similarly odd sum. This curious bill was also paid, but when the patient met his physician, he inquired, 'How, doctor, did you ever get that odd ninety-two cents in my bill?' 'Oh,' said the doctor, 'that is easily explained: my grocer's bill was for just that amount, and I knew of no one who would so cheerfully pay it as yourself, and so I made one pay the other.'"

The Physiology of Tears.—Dr. Daniel Tuke, who has been investigating the physiology of tears, thinks we must confess with Brodie that we cannot answer the simple question why or how does a certain state of mind augment the secretion of the gland? Gratiolet inferred, partly from his own sensations, that tears result from reflex irradiations which traverse the fifth pair of nerves; that is to say, the emotion of joy or sorrow acts first upon the heart or other viscera through motor channels, and is then reflected upon the sensory nerve supplying the gland. But this track does not seem anatomically or physiologically justifiable. Much more likely it is that the influence is transmitted directly either to the capillaries of the gland by actively dilating motor nerves, or through nerves to the lachrymal cells themselves, directly exciting their functional activity. We might apply to the lachrymal gland, Sinitzin's conclusions in regard to the trophic influence of the cervical sympathetic and the fifth pair on the eyeball; but some difficulties present themselves, into which, however, we cannot now enter. The *quality* of the secretion seems to be altered by powerful emotions; the saline ingredients being increased, causing "a strong brine." Lastly, the secretion may be checked. The intensity of the feeling or the suddenness of the sorrow is the

most frequently witnessed cause. Daily observation shows that the first result of distressing intelligence is the negative one,—inability to cry. See, too, what the want of a handkerchief may do. "I went," says Hunter, "to see Mrs. Siddons acting. I had a full conviction that I should be very much affected; but, unfortunately, I had not put a handkerchief in my pocket; and the distress I was in for the want of that requisite when one is crying, and a kind of fear I should cry, stopped up every tear, and I was even ashamed I did not, nor could not, cry."—(*Posthumous Papers*, vol. i. p. 257.)

The Oldest Man in the World.—Jacob Fournhis, who was probably the oldest man in the world, died recently at Kansas City. He was about one hundred and thirty-eight years old, and remembered distinctly the taking of Quebec by Wolfe, in 1759. He followed the occupation of a hunter for fifty years, and retired about thirty years ago from active work.

A Well-Merited Recompense.—Under this heading the *Mouvement Médical* of September 14 says, "Our readers are well acquainted with the features of *l'affaire Dolbeau*. They know also of the curious inquiry which was made and which we have published;—the share taken by M. Dolbeau in the arresting of one of his hospital-patients is unfortunately beyond a doubt. They know also the appreciation of all the circumstances by M. Béclard." (M. B. was vociferously applauded for some remarks on professional honor, made by him to the students with tacit reference to M. Dolbeau's course.) "M. Dolbeau has now received the reward of his conduct. In spite of all protestations, too well justified, the administration has intrusted M. D. with the inspection of the preparatory medical schools, and with presiding over the examinations for the degree of *officier de santé*. After all that has passed, this official action is somewhat surprising. We shall see how the matter will end."

Evidently, lively scenes are anticipated.

The London *Lancet* says, "The subject of tattooing has acquired a temporary interest from the incidents of the Tichborne trial. The practice is of great antiquity, and, as is well known, is adopted by many savage tribes. The mode in which it is performed, however, varies considerably. Thus, while the Australian makes deep incisions, and fills in the wound with clay and other substances, so that an elevated scar is left, the New Zealander scarifies himself with an instrument resembling a curry-comb, constructed of shark's teeth, which is slowly driven through the skin by repeated blows of a mallet, the wounds being filled with the resin of the Kauri pine and a kind of red earth. With the lower classes, and, it would appear, with youths of the upper, in this and neighboring countries, the punctures are made with a needle; gunpowder, indigo, or vermilion being subsequently rubbed in. By wild tribes, tattooing is unquestionably used as a substitute for clothing, and Prichard, as quoted by Wood in his 'History of Man,' observes that European eyes become so accustomed to the tattoo that they are rather shocked at its absence; and so completely is this feeling realized by the Samoan natives, that chiefs who have arrived at middle age frequently undergo the process of tattooing a second time, in order to renew the patterns, as they become dim and uncertain with the lapse of years; for, though indelible, the tattoo does fade in time. Tattooing, so common among our sailors and soldiers, is probably based upon a desire that their bodies may be recognized in case of death in action or by drowning; though it is, perhaps, often done merely from imitation, or to while away the time. The durability of the marks will obviously depend on the depth of the incisions or punctures, and the nature of the substance rubbed in. When the incision or puncture has fairly penetrated the cutis, and the material is insoluble, it will certainly be permanent. Virchow, in his 'Cellular Pathology,' gives an illustration of the appearance presented by glands of a tattooed soldier fifty years after the operation."

Entozoon of Fish.—At a meeting of the Medico-Chirurgical Society of Edinburgh, Dr. Handyside read an account of *Filaria Piscium* within the muscles of a salmon. This entozoon, not uncommon in the branchiæ and in the intestinal canal of fish, is not hitherto described as occurring free in the muscles. Thirty-four were found alive and wriggling in the muscular substance of a small slice of a fish, the rest of which had been sold to the public. Dr. Handyside gave a careful description of the appearance and general anatomy of these entozoa, and detailed some experiments which gave the reassuring results that a very slight increase of temperature over 98° was soon fatal, and even the removal of the worms from the muscles to water was sufficient sooner or later to kill them; so that little danger seemed to exist of these retaining their vitality in the human stomach. Dr. Rutherford Haldane suggested that in the event of another example of a fish infested by these parasites being obtained, experiments should be made by feeding cats or other animals with the flesh and watching the results.

Deaths from Lightning.—During the months of July and August, 1872, *thirty-six* persons were killed by lightning in the Northern and Eastern States of our country. During the ten days succeeding July 3, no less than fifteen persons were killed by this means in these States. A writer in *Appletons' Journal*, September 9, 1872, truthfully remarks that "a succession of three railroad accidents, in each of which five persons had been killed, would have horrified the community; but these fifteen deaths by lightning seem to have attracted very little attention. From the report of Boudin, presented to the Academy of Sciences in 1864, we learn that in France, during twenty-nine years, an average of seventy-seven persons lost their lives, and 232 were injured, per annum. In Mecklenburg it was found that one person was killed out of every 247,200 inhabitants."

Coagula from the Ureter (*Column for the Curious: Brit. Med. Journ.*, July 2, 1872).—I do not recollect any reference being made in a modern work to this

curious result of renal hemorrhage. A short time ago, I was shown coagula voided from the bladder, and evidently moulded in the ureter, which bore a striking resemblance to small specimens of ascaris lumbricoides. The following is from Boerhaave's Institutes, English edition, 1746, vol. vi.: "When blood extravasated into the pelvis of the kidney congeals into grumes, as they pass from thence into the ureter and bladder, an obstruction is by this means generally formed, either in the ureter or urethra. I have myself seen blood concreted so as to put on the shape of a worm in the urethra, from whence we were obliged to extract it by a hook. Of this disorder perished that considerable anatomist Drelincourt."

According to a statement made at the Statistical Congress, held this year in St. Petersburg, the total number of deaths from smallpox in the German army during the recent Franco-German war was two hundred and sixty-three. This small mortality is attributed to the system of compulsory revaccination, which every man who enters the army must undergo. On the other hand, in the French army, where revaccination is not compulsory, the number of deaths, as stated by a French authority, was 23,469. This terrible difference, says the *Wiener Medizin. Wochenschr.*, must puzzle the greatest opponents of vaccination.

Receipt against Cholera.—On the occasion of a great epidemic—probably one of cholera—which reigned in the seventeenth century, the following quatrain had much vogue. *La France Médicale*, which has disinterred it, thinks it still applicable.

"Tiens tes pattes en chaud,
Tiens vides tes boyaux,
Ne vois pas Marguerite,
Au cholera tu seras quitte."

According to the *New York Medical Record*, the New Sydenham Society have purchased the copyright of Dr. Mayne's Dictionary of Medico-scientific Terms, which is to be made the basis for a new work of this description. A small staff of editors will be appointed to undertake the task of revision and supplement, and the profession at large is invited to co-operate in furnishing suggestions, emendations, or additions towards the completion of the work.

Death of the English Medical Director-General.—Sir Andrew Smith, Director-General of the English Army Medical Department, died recently, at the age of seventy-five. He was a Scotchman, spent a great portion of his life in South Africa, and, among books on that colony, his "Illustrations of the Zoology of Southern Africa" is well known.

British Medical Association.—The next meeting of this Association will be held at Bradford, September, 1873. Belfast is the place chosen for 1874. Dr. James Prescott Joule is the President elect.

The tenth annual meeting of the British Pharmaceutical Conference will also be held in Bradford next year.

New York Physicians.—According to the New York *Medical Register* for 1872, there are in New York City, Brooklyn, and vicinity, seventeen hundred and forty-eight practising physicians in good standing, being a gain of one hundred and ninety-five over the year 1871.

University of Zurich.—The Professors of this University are unanimously opposed to the admission of any more female students, and intend to apply to the Federal Government of Switzerland for a bill restricting the rights of studentship to males.

A Nut for Vital Statisticians.—It is stated as a curious fact, on the excellent authority of our contemporary the *Edinburgh Medical Journal*, that during the strike of the scavengers in Edinburgh the mortality of that city fell to 15 per 1000.

Among the candidates who lately passed the anatomical examination in the University of Berlin with special approbation, was a Japanese student named Sasumi Satoo, son of the private physician of the Mikado.

Mt. Sinai Hospital, N.Y.—This new and commodious hospital, on Lexington Avenue, N.Y., was formally opened on the 29th of July. Gov. Hoffman presided and made a short address.

Death of Prof. Czermak.—Prof. Czermak, of Graz, the well-known psychologist, Director of the Styrian Insane Asylum, etc. etc., died at his post a few weeks ago.

Mrs. Peter Charron, of Ware, Mass., died a few days ago, after twenty-six years of married life, during which time she had twenty-two children, all at single births.

Prof. Wm. Warren Greene, M.D., of Maine, has accepted the chair of surgery in the Long Island College Hospital, Brooklyn, N.Y.

Boston University.—Dr. John Ordronaux has been appointed one of the Faculty in the Law School of the Boston University.

Mortality of Philadelphia.—The deaths reported at the Health Office for the week ending October 19, 1872, were 250; of which 124 were of adults, and 126 of minors. Among the causes assigned were:

Consumption of the Lungs	47
Other Diseases of the Respiratory Organs	29
Diseases of the Circulatory Apparatus	10
Diseases of the Brain and Nervous System	30
Zymotic Diseases*	16
Typhoid Fever	5
Cholera Infantum	3
Dysentery	1
Casualties	12
Murder	2
Debility (including "Inanition" and "Marasmus")	31
Old Age	8
Still-born	18

* Including 2 from smallpox.

SATURDAY, NOVEMBER 2, 1872.

CLINICAL LECTURE
ON CONGESTION OF THE SPINE.

BY DR. H. C. WOOD, JR.

Physician to the Philadelphia Hospital; Clinical Lecturer on Diseases of the Nervous System to the University of Pennsylvania.

LECTURE II.

THE treatment of these cases is often very satisfactory in its results. General blood-letting is certainly, in most cases, not indicated, but possibly may be useful in some cases, when the individual affected is very robust. Local blood-letting is, I think, in many cases indicated, and ought to be vigorously practised. When the attack has been produced by suppression of a hemorrhoidal or uterine discharge, it seems to me that the most natural method of local blood-letting would be the application of leeches to the neighborhood of the anus, or in the latter case even to the uterus. As an adjuvant in these cases, and as a main reliance in others, I would advise the free application both of cut and dry cups along the spine.

Cut cups should not be used too often, yet dry cups may, I think, be frequently repeated with advantage. Although we may not be able to explain how counter-irritation acts, yet it seems to me that to deny its value in the face of our daily experience, is as absurd as it would be for a savage to deny the existence of light because he did not know how it influenced the brain. Of all forms of counter-irritation, dry cups are the most efficacious in deep-seated congestions, and, as they scarcely affect the general powers of the system, may be freely used.

As to drugs, there is one remedy which appears to have the power of acting upon the muscular coats of the vessels, either directly, or, as is more probable, through the vaso-motor nervous system. Although the contrary has been asserted, yet there is no sufficient reason to believe that ergot acts any more powerfully upon the blood-vessels of the cord than upon other arterioles. It appears to be, however, a law, that where there is a loss of nerve-tone in the muscles of a part, these muscles first feel the influence of a stimulant drug. Hence it is not improbable that in cases of spinal congestion the relaxed vessels of the cord are sooner affected by the ergot than the general capillary system. Although I use, and would recommend, ergot in these cases, it is but fair to say that its real value is by no means certain. I have never employed it except in connection with more efficient measures; and indeed it is in this way almost universally that others have used it. When with this circumstance the fact is borne in mind that a large proportion of cases spontaneously slowly ameliorate, even to perfect recovery, it becomes evident that it is much easier to *assert* than to *prove* the value of the drug. Dr. Hammond details, however, a case in which ergot used alone did seem to be of value.

To be of value, ergot must be given in large doses: a drachm and a half or even two drachms of the fluid extract three times a day. There can be no doubt but that this remedy acts with extraordinary efficiency when given hypodermically. Unfortunately, when so employed, it is so prone to cause severe local inflammation, that only the most urgent necessity justifies its use. I had received from Merck of Darmstadt some of the alkaloids of ergot, and tried them hypodermically in the present case; the result was an intensely sore arm, which at one time threatened serious consequences, and which only got well after the lapse of several weeks.

The electrical treatment is of great importance in congestion of the spine. It resolves itself into two portions,—faradization of the muscles to keep up their nutrition, and the application of a continued current of moderate quantity and considerable intensity to the spine.

The faradization should be practised in such a case as the present only to each half of the body on alternate days, so that every muscle receives a thorough faradization every other day.

The electrical treatment has been continued uninterruptedly to the present date (Sept. 10). By the 1st of July she was able to walk with the assistance of the nurse. The muscles of the legs were not all wasted, and responded well to induced currents. The feeling of numbness and formication had also nearly vanished from the legs.

The movements of the right arm were good, although she had not recovered much power in them, and the muscles of the arm responded pretty well to the induced currents. The skin of the left arm, which had presented the peculiar appearance of chronic paralysis, had now become healthy, and she was able to raise the hand by the wrist-joint from the bed. There was in the arm proper very little response to the galvanic current.

During the intensely hot weather of July and August, our patient suffered from a glandular abscess in the neck, and excessively from the heat, and has made but slow progress; but she has really made some progress, except in regard to the left deltoid, which has almost disappeared. The remaining muscles of the left arm are certainly not so wasted as they were.

Oct. 16.—Owing to circumstances not necessary here to detail, the electrical treatment has not been as regularly carried out recently as it should have been. The woman, however, is much improved, walks quite strongly, and has perfect control over her right arm. There has not been much gain in the power of voluntary movements of the left arm; the muscles, however, with the exception of the deltoid, all respond to strong secondary induced currents.

For the superficial muscles I prefer the primary induced current (current of the first coil of Duchenne); for the deeper one, the secondary current (current of the second coil of Duchenne). The reason of this is not because I believe there is any therapeutic difference, except in penetrative power, in the two currents, but simply because the greater intensity of the secondary current enables it better to reach the deep muscles. Of course with this faradization passive motions, shampooing of the limbs, and sim-

ilar measures to prevent stiffness and maintain nutrition, should be sedulously practised.

The use of the continued current to the spine is very important, and it is a matter of moment to decide, if possible, the best method of its application. Shall it be a downward or an upward current? Hammond is very decided for a descending current, but Legros and Onimus are even more positive for an upward current. The probabilities are that it makes no difference whether the positive pole be placed above or below the negative. In the present instance a descending current has alone been used. The applications have been daily, with more or less regularity, and each has lasted about fifteen to twenty minutes. The battery used was a Stöhrer, fifteen to twenty cells being brought into requisition.

Our patient took the ergot steadily from the 26th of May to the 20th of June, and had the regular use of both of the constant and interrupted currents (the strength of the former being that of sixteen cells of Stöhrer's battery). During this period she improved very markedly, so that at the last date she could sit up in an arm-chair for three or four hours, and could almost retain her urine at will. After the 20th of June no medicine was given, except some appropriate remedies for dyspeptic symptoms. She had complained bitterly of a neuralgic pain in right elbow and shoulder for some time, but these were relieved by small fly-blisters placed over the painful part.

ORIGINAL COMMUNICATIONS.

A CASE OF HÆMATURIA.

BY W. D. MARTIN, M.D.

THE subject of this account was a gentleman fifty-four years of age, who had always enjoyed uniform good health; he rode eight miles in an open wagon, the temperature being below zero, during a tempestuous day in the last week of December, 1871. Sitting upon straw in the bottom of the vehicle, he experienced such severe local cold posteriorly that for warmth he had recourse to stuffing straw under him, and was compelled, so far as possible, to use his overcoat and shawl for the same purpose. He arrived at his destination suffering generally from the effects of exposure to cold.

The urine was casually noticed to be somewhat highly colored for a few days, and so continued until he observed, particularly while at the house of a friend, on January 8, 1872, that the urine voided into the vessel after a night's rest was of a very dark-red, cloudy, and unnatural color. Thenceforth, without either pain or a desire to micturate oftener than usual, he nevertheless continued to pass urine of the character described, and the above facts were elicited when I first saw him on the 18th inst. He was strong and cheerful, and blood-stained urine was the solitary symptom in the case.

An attentive examination of the urine with the microscope failed to reveal any of the products of Bright's disease, and several chemical analyses showed no notable results. A circumspect search for albumen revealed no more than was expected from the presence of blood. The urine passed in twenty-four hours was normal in quantity, the blood during micturition was intimately mixed with it; there was no tenderness upon careful pressure over the kidneys, no local tenderness along the urethra or in the vicinity of the prostate gland; the introduction of a bougie caused no uneasiness whatever, nor was its withdrawal followed by any bloody discharge.

Under these circumstances, astringents and hæmostatics of all kinds were brought to bear, and he took, without avail, gallic acid in large doses, tinct. ferri chl., gtt. xx four times a day, turpentine, balsam of copaiba, in doses of gtt. xl,* erigeron, ergot, alum, buchu, uva ursi, etc. etc. These medicines were used both singly and in varied combination, and a week generally allowed to every new trial. Rest and astringents having thus been proved useless, he was advised to resume his business, with the hope that relief from an irksome confinement of many weeks' duration, fresh air, exercise and tonics, with the moderate use of ale or porter, might prove beneficial.

May 18.—The patient has been travelling constantly, in pursuit of business. He complains of being easily tired, but has not lost flesh, and looks well. Bloody urine is now voided *first*, the remaining and clearer portion following.

Dr. H. L. Orth, of Harrisburg, who examined some of the urine for me at that time, says:

"Two specimens were received by me: one two-ounce bottle with urine passed at 5 A.M., and one four-ounce with that passed at 12 M.

The morning urine was opalescent, of urinous odor, acid, sp. gr. 1020; and with the usual tests a small quantity of albumen was thrown down. On standing three hours it still remained acid; the resulting deposit (about one drachm) was a dense cloudy mass, and consisted of mucin, blood, pus, spermatozoa, epithelial cells from the bladder and urethra, and a few oxalate of lime crystals. Pus was inferred from the fact of the red and white corpuscles being in abnormal proportion, 3 to 1, while, as you well know, the normal is 390 to 1.

"The second specimen was of a light smoky appearance, of urinous odor, sp. gr. 1016, and after standing three hours deposited about two drachms of a light brick-red and very dense deposit which consisted of mucin and epithelial cells in small quantities, and red and white blood-corpuscles in almost normal proportions; that is, the blood in the urine passed at 12 M. was nearly pure."

The course of the hemorrhage at this time seeming to be intermittent in character,—on some days worse and again negatively better in appearance,—the sulphate of quinine was liberally administered in conjunction with the tincture of the chloride of iron, but without benefit. His final prescription in August I mention here, from the conviction that it proved beneficial in some respects:

* Abstract of the Medical Sciences, vol. xlv. p. 103.

℞ Zinci valerianatis, gr. lx;
Quiniæ sulphatis, gr. xxx;
Acaciæ pulv., q. s.
Ft. pil. No. 30.
S.—One morning and evening, every second day.

℞ Syrupi ferri phosphatis, ℥xx;
Acidi phosphorici diluti, ℥iv. M.
S.—One drachm in ℥j of water after dinner and supper, every second day. The pills and the mixture to be taken on alternate days.

October 15.—And now, after constant hæmaturia for ten months, he still continues to pass blood-stained urine without pain, but in general health and strength was never better; having lately gained considerably in weight. He says that on some days the urine is still unnatural in color, but that a drink of gin often clears it for a whole day.

As to the cause of this hæmaturia I will not hazard an opinion, but will say that it does not seem to be from hemorrhagic predisposition, and certainly not from malignant disease, as the affection positively appears no worse than when first noticed by me in January.

With reference to the source of the hemorrhage, I will state that I do not know; I leave that to the consideration of those who may be interested in this report.

ICE TO THE NECK IN HYSTERIA, AND IN SUSPENDED RESPIRATION.

BY J. T. ROTHROCK, M.D.,
Wilkesbarre, Pa.

IN March, 1872, I was requested by a dental friend to administer an anæsthetic to a patient, for the purpose of extracting a number of teeth. Notwithstanding the dread of the patient in regard to inhalation of chloroform or ether, caused by supposed cardiac and pulmonary trouble (a dread in which I did not share), I discovered on actual trial that she evinced a remarkable toleration of it, so much so that an unusually large quantity was required to produce complete anæsthesia. The teeth were extracted, and while we were awaiting a return of consciousness, hysterical symptoms manifested themselves. These culminated in one prolonged, terrific fit of hysterical noisiness. For fully an hour the patient screamed, so loudly as to set at rest any lingering doubt as to the healthy condition of her lungs. The usual restoratives were vigorously plied. Antispasmodics in turn failed. Within convenient reach from the window lay some snow. I made a snow-ball of it, and on applying it to the forehead obtained some remission in the screams of the patient; but after a faithful trial I found her still unrestored, and still noisy enough to disturb the neighborhood.

I then tried the same remedy to the neck along the line of the sterno-cleido-mastoid muscle. Within a minute she gave a deep sigh, opened her eyes, looked rational, and the hysteria showed evident signs of vanishing, as it did very soon after.

In September of the same year, I was called to see a nervous, delicately-organized woman, who had, on the death of her child, fallen upon the floor in a paroxysm of hysteria. When I reached the house I found her still lying where she had fallen, insensible, and in a state of clonic spasm, which closely simulated poisoning from strychnia. Mustard was freely applied to the wrists and ankles, and as much bromide of potassium given as could be forced, in concentrated solution, between her firmly-locked jaws. These remedies, on which I have learned to rely in like cases, seemed to fail me utterly here, after a fair, persistent trial. I then applied a lump of ice to either side of the neck, stroking it up and down lightly in the same line as I had the snow-ball in the previous case. Again I obtained a deep, satisfactory sigh within a minute. So long as I allowed her to remain without the ice-application, or applied it to the forehead or face, she ceased to take full inspirations, and went back into spasm. On applying it again, and maintaining its action, the sighs followed, and with them came relaxation of spasm and easy breathing, which within an hour terminated comfortably in consciousness. From what I afterwards learned of this same person I found that she was in the habit of having these hysterical paroxysms, and also that they never before had terminated so soon as did this one.

Within two weeks of the above case I administered a mixture of chloroform and ether to a plethoric lady. The anæsthetic was pushed to the point of marked stertorous breathing. Her return to consciousness was so slow as to alarm her friends, and I was urged to "do something." I applied the ice as in the preceding case, and almost instantly the same sigh followed. Keeping up the ice to the neck, she awoke in an unexpectedly short time, considering how profoundly she had been under the influence of the anæsthethic.

These cases are simply three from quite a number I could give. They are sufficient, however, for my purpose.

Now, how did the remedy act? Certainly not by mere pressure upon the blood-vessels; for it was quite too lightly applied to influence in any way the quantity of blood in the brain. Nor yet by mere pressure upon the nerves of the part; for Waller, page 193 et seq., vol. ii. of *The Practitioner* (English), has proven in a highly suggestive article that pressure there, affecting the nerves, is followed by a *heaving respiration, but also by syncope*, of which latter there were no symptoms save a muscular relaxation, which was natural in any condition of rest.

To my mind the most probable explanation is that the mere shock of a cold substance to the surface had something to do with recovery (this no one will probably deny); but that, superadded to this, there was supplied through the pneumogastric nerves in this superficial position to the medulla oblongata, the *besoin de respirer* of which in its obtunded state it had taken no cognizance.

Be the explanation what it may, I infer from actual trial that the remedy may be advantageously used in cases of obstinate hysterical paroxysms, and of tardy return to consciousness from anæsthesia.

By analogy, I infer it may prove of service also in cases of suspended respiration from drowning, hanging, etc., and possibly also from decided overdoses of anæsthetics.

TWO CASES OF MALARIAL DIARRHŒA.

BY H. G. LANDIS, M.D.,
Niles, O.

MRS. W. B., æt. 32, was delivered September 10 of her twelfth child, after a hard labor and the use of instruments, due to pelvic deformity and an enormous child. She had repeatedly suffered from similar labors. On the following day she was put on an antiphlogistic course of treatment, in order to be prepared for the inflammation, which seemed after such a labor almost inevitable. On the 12th, a small dose of ol. ricin. was taken, after which she had several evacuations. On the 13th, considerable inflammation of the vagina existed, and the bowels became very loose. Hops were applied locally in the form of a poultice, and all other treatment but morphia suspended. The diarrhœa persisting, opium and tannic acid were used freely until the 19th, when both the diarrhœa and vaginitis were at an end. After this she did very well, sitting up on the 24th, and walking out on the 26th, until on the 27th another attack of diarrhœa commenced, occurring every night without either chill or fever, and not troubling her in the daytime; differing in this respect from the former attack, which was irregularly continuous. On October 1, I first became aware of this condition, and gave bismuthi subnitr., myristicæ, āā gr. x, every four hours, which had no effect whatever. Guided only by the periodicity of the attacks, I gave her quinine on the 3d, which promptly stopped the diarrhœa in one day.

D. P., æt. 35, applied for treatment September 21. He had suffered from diarrhœa for three weeks, and was now passing some blood and pus. As in the former case, he was only troubled at night, but, being daily engaged at hard work, was occasionally chilly, and subject to cold perspirations, for which his weakened condition would fully account. He could assign no reason for the attack, and I gave him opium, bismuth, and myristica, which gave him one night's rest, and then failed to exercise any influence. On the 24th this was changed for quinine in three-grain doses, which immediately stopped the diarrhœa.

A noteworthy circumstance in these cases is that they occurred in adjoining houses, and at about the same time. In neither case was there any malarial cachexia, nor even a well-marked paroxysmal advent of the diarrhœa, for its occurrence at night was at irregular hours. The phases of the poisoning in a very malarious district are often curious, nearly every disease occurring during its prevalence being more or less complicated by it; but the occurrence of a distinct disease, due to this cause, and yet giving no sign except the doubtful one of nocturnal recurrence, is worthy of more attention than has been paid to it. It seems highly probable that these irregular manifestations of malaria will ultimately have a prominent part in solving its origin. With the existing theories of the disease, these cases point either to a possible resistance of the intestinal tract to the absorption of the miasma, or to an elimination of it from the body. Now, if the first alternative could be sustained, a very important suggestion arises, viz., that a paroxysm of intermittent fever has its determining cause outside of the body, and that each paroxysm is a separate attack from without; a sort of "swarming" of the disturbing organisms on the affected person. If they fail to enter the body, only a local irritation follows; otherwise the ordinary phenomena succeed. It is, however, better for the present to call attention to the bearing of these and similar cases, rather than to elaborate any theory on insufficient materials.

NOTES OF HOSPITAL PRACTICE.

JEFFERSON MEDICAL COLLEGE.

CLINIC OF PROF. S. D. GROSS.

Reported by FRANK WOODBURY.

HÆMATOID TUMOR.

SEPTEMBER 28.—This young German, twenty-two years of age, was brought here by his physician from Mauch Chunk, Pennsylvania, on account of a tumor on the anterior aspect of the right elbow-joint. This, he tells us, has existed for eighteen months, and he first noticed it about three months after receiving a severe blow with a stick, upon the part, which bruised and broke the skin. This tumor has been persistent, gradually attaining the size of a hen's egg, and deprived him of the use of his arm by the pain which was produced by moving it. Eight weeks ago his physician commenced an operation for the removal of the tumor. He made a subcutaneous exploratory incision, by entering a bistoury under the skin about an inch farther down the arm and running it up into the swelling. This was followed by profuse hemorrhage, which, although finally controlled by cold applications, deterred him from proceeding further. This sinus has remained open, and the flow of blood recurring at short intervals has rendered the patient almost exsanguineous; his face is anæmic and pallid.

We find here œdema of the hand and forearm, undoubtedly produced by this circumscribed tumor in the bend of the elbow, which, by pressing on the superficial veins, obstructs the return of the blood from the parts and forces some of its watery constituents through the coats of the smaller vessels. On examining this tumor we find it circumscribed, with considerable hardness and some fluctuation, and a sensation as if it contained a semi-fluid substance. This inclines me to the opinion that it may be of a nævoid character or a blood-cyst, caused by the injury. It is not an aneurism of the brachial artery, as it is not in the line of that vessel, and there is no pulsation or aneurismal thrill. A grooved director passes readily up the sinus into the swelling, and its withdrawal is followed by the flow of a few drops of a ropy, glutinous, grumous fluid.

What I propose to do, after administering chloroform, is to insert a grooved director into the sinus and slit up the skin as far as the tumor. I am not prepared to state positively the exact nature of this affection, whether it is aneurismal or nævoid, malignant or benign; my object is to prevent future hemorrhage, which, if allowed to continue unchecked, would undoubtedly prove fatal. The indication is, therefore, to cut down and remove the cause if possible. We will tie any vessels we meet, as we proceed, as he is not in the best condition for the operation and can ill afford to lose any more blood. We find the parts in the neighborhood very vascular, and all the small vessels are enlarged;

ligatures are of no use, as the blood flows, not from one or two, but literally oozes from a thousand points. During the operation the brachial artery is compressed by an assistant. The tendon of the biceps muscle passes directly over the tumor, and must, therefore, be divided in order to enucleate the cyst. The sac of the tumor, which is quite thick and contains a number of enlarged veins, is evidently formed by interstitial deposit in the connective tissue, which sends fibrous bands into the interior, resembling the musculi pectinati in the ventricles of the heart. Its contents are partly fluid blood, and the remainder is grumous and clotted, proving its traumatic origin.

The wound, which is quite deep, we will now fill with cotton wadding dipped in Monsel's solution, which has powerful styptic and antiseptic qualities. A roller bandage will be applied upon the hand and forearm, and the limb kept elevated. He shall have an anodyne immediately; we will give him half a grain of morphia, which is much better in these cases than smaller doses. In order to keep down inflammation and avert hemorrhage, ice will be applied to the part, for the same reason that ice is applied to the head in cerebral meningitis, to reduce the heat and morbid action; the same care, however, must be exercised not to allow it to remain too long in contact with the surface, lest it should freeze the part and produce sloughing. He must remain in bed for a day or two, until the danger from hemorrhage is over; to avoid this, as the brachial artery may be extensively diseased, a tourniquet will be loosely applied around the arm, ready to be used in an emergency. As his system is in such a depressed condition, we will bring it up with a nourishing diet, with animal broths and a glass of milk-punch every day, and the administration of iron and quinine.

Twenty-five years ago, when bleeding was much more frequently performed than it is now, effusions of blood in the cellular tissue, with the formation of a bloody cyst, or hæmatoma, as it is now called, quite commonly resulted from venesection in the arm. Occasionally the lancet pierces the artery and forms an aneurism. In such a case the best plan of treatment would be to cut down upon the artery and tie it above and below the lesion. I remember, when in Louisville, a man came to me whose arm, in consequence of a venesection, had become swollen and dark-colored from the wrist to the axilla. Erysipelas had ensued, exhausting the patient and threatening his life. I ligated the artery above and below the point of injury, laid the parts open freely, turned out the blood, and saved the man. The young practitioner who attended him was afterwards mulcted in heavy damages, although I do not think that he was to blame, as such an accident might follow any venesection.

October 19.—The wound has entirely filled up with granulations. The styptic cotton was allowed to remain in the wound for three days, at which time suppuration commenced and the healing process began. He has been using the oxide of zinc ointment, which is especially adapted to cases where there is irritation of the skin, such as itching or pruritus, but does not possess any cicatrizing qualities. We will therefore suspend its use, and apply instead the acid nitrate of mercury ointment, which is a powerful cicatrizer; this should, however, never be used in the full strength as sold in the shops, which is too stimulating, but should be diluted in the proportion of one part of the ointment to ten parts of lard, and be applied on a piece of lint.

The muscles are stiff from want of use and from interstitial deposits. The inflammation resulting from the operation has caused an effusion of plasma among the muscles, and has extended into the joint, producing false ankylosis. To overcome this, passive motion must be used twice in the twenty-four hours, performed gently at first, so as not to interfere with the healing process or produce fresh inflammation. The limb is to be washed daily with warm water and a little soap, so as to stimulate absorption. The patient has much improved since the operation, both in appearance and condition. The treatment, with daily open-air exercise, will be continued for a short time until he is perfectly well.

AN UNUSUAL CASE OF HYDROCELE.

This interesting specimen was furnished by Dr. Barton, chief of my surgical clinic. The patient from whom it was obtained, a man thirty-five years of age, has been troubled for several succeeding summers by a great increase in the size of his scrotum, which, during the winter months, gradually resumed its natural condition. This summer it was more distended than ever. In June, Dr. Barton drew off with the trocar eight fluid-ounces of a fluid resembling milk in color and consistency; three weeks later seven ounces were removed, and on the 12th of this month six ounces more, somewhat darker in color; which is here exhibited.

The fluid of hydrocele, especially in young subjects, is, as a rule, a pale, watery liquid, but sometimes of a pale sherry color. This always contains a large amount of albumen, which coagulates by heat. In rare cases, by reason of its containing in addition a quantity of fatty matters, especially of a micaceous-looking substance known as cholesterin, it assumes this color. From a careful analysis of the fluid in this case, made by Dr. Barton, I am enabled to give you its chemical composition. It was found to contain sulphate of soda, tri-basic phosphate of soda, chloride of sodium, urea, albumen, fat, and water. On microscopical examination the field was filled with fat-globules, which were entirely soluble in ether.

SPERMATORRHŒA.

This patient, a young man of twenty-two years, has suffered from frequent seminal losses during the past eight or nine years; the primary cause he considers was masturbation. The discharges occur several times a week during sleep, and he also thinks that some passes off in the urine. He is troubled with indigestion and constipation, is depressed in spirits, and his general health is undermined.

This is a not unfrequent result from a practice which, I regret to say, is not exclusively confined to the male sex; and is generally acquired while at school. The continued irritation of the genital organs induces an erethism of the entire genito-urinary tract, the parts being in a state of unnatural excitation. This determines more blood to the organs, and slight causes are sufficient to induce erections and seminal losses, generally at night. At first these emissions occur during sleep, towards morning, accompanied by a lascivious dream and sensation. Ultimately, as the parts become more enfeebled, the discharge occurs without sensation, consciousness, or erection, not being discovered until the succeeding morning, or it may even occur during straining at defecation. This may continue for years, ruining the health and depressing the mind, especially if the exciting cause is continued. The individual constantly broods over his condition; he cannot look his fellow-man in the face, and shuns society; if he sees a friend coming towards him in the street, he will, in all probability, cross to the other side to avoid him. This may end in settled melancholy, epilepsy, or insanity.

This affection can only be confounded with prostatorrhœa, which consists in the discharge of a few drops of mucus from the prostate gland and urethra, taking place either in expelling the final drops of urine, during defecation, or from excitement. Emissions taking

place in the daytime are generally of this character, while those at night are true seminal fluid. But seminal losses, within physiological limits, do not constitute a disease. Every man in health has occasional emissions, which generally occur during sleep, under the influence of a dream. It is only when these become abnormally frequent that the disorder is called spermatorrhœa, affects the patient's health, and calls for treatment. His statement that he lost the fluid during urination is incorrect. It never passes off in that way, as is proven by a microscopical examination of the urine. It is true that a few spermatozoa may collect at the prostatic portion of the urethra and be swept off by the urine; but if there was an actual mingling of the two fluids, this element would be present in much larger quantity.

Where the case is plainly one of spermatorrhœa, treatment should be instituted promptly. Milder cases will generally recover spontaneously after withdrawal of the exciting cause, by proper attention to the diet, avoiding anything of a stimulant character, and invigorating the system by cold baths and exercise. In chronic cases the best treatment is cauterization of the prostatic sinuses, to remove the hyperæsthesia of the ejaculatory ducts. These are in a state of morbid sensibility, and our object is to remove this condition so as to lead them back to their natural condition. An instrument was devised for this purpose by Lallemand of Montpellier, who wrote a book on this subject. His instrument consists of a catheter, from whose extremity a cup, containing a stick of lunar caustic, is made to project by pushing in a stylet at the handle. One objection to this instrument is that in several cases, in which it was used, the caustic broke off in the urethra and gave trouble. To obviate this, I modified the instrument, many years ago, by having it closed at the vesical extremity, near which, on its convex surface, is a fenestra, which is placed over the desired spot, and a little cup containing powdered nitrate of silver is brought opposite it and in contact with the part, by pushing in the stylet. This instrument we will now use, introducing it as an ordinary catheter until we have reached the proper situation, where it is allowed to remain for a few moments, and is then withdrawn slowly, so as to extend the impression along the urethra. After this operation there will be some pain and scalding, and an anodyne should be given. I generally prefer in these cases two drachms of paregoric or one-sixth of a grain of morphia. The operation may be repeated at the end of eight or nine days; it must not be performed too frequently, as it would do harm. Three or four applications, in most cases, are all that will be required to effect a cure. All sources of irritation should be avoided. The bowels should be kept in a soluble condition by some aperient laxative, and the general health improved by tonics, open-air exercise, cold bathing, and a nourishing diet.

SYPHILITIC ULCERATION OF THE FACE.

This young married woman has a number of superficial ulcers involving the upper lip and the entire nose, which is partly destroyed. These extend from the eyes down to the mouth, are covered with spoiled lymph, and tell their own story. The patient lives with her husband, who is healthy, and she denies ever having the primary lesion, sore throat, or eruption on the skin, but I am, nevertheless, convinced that it is nothing but syphilitis. Why it selected the face in preference to the legs, or the skin instead of the lymphatic glands, hair, periosteum, or bones, no one can tell. You can judge positively from its appearance that this is not cancerous, as it has not the aspect of an epitheliomatous sore.

Now, what should be done here in the way of treatment? To treat it locally, only, would be the height of folly; we will, therefore, also give our constitutional remedies. The iodides, either of potassium, sodium, or ammonium, produce almost a specific effect in this disease, especially when combined, as I am in the habit of using them, with a small quantity of the bichloride of mercury. Nausea, produced either by too large doses or a too long continuance of them, must be avoided, as it would depress the patient. We commence then with a small dose, and will increase it judiciously.

℞ Potassii iodid., gr. viij;
Hydrarg. chlorid. corros., gr. $\frac{1}{10}$. M.

Take either directly before, or an hour after, each meal. The diet must be light and nutritious, and the skin must be kept clean, avoiding taking cold. As a local application to promote cicatrization,—

℞ Liq. hydrarg. nitrat., gr. x;
Aquæ, f℥j. M.

Use once a day, and have a cloth wet with—

℞ Liq. plumbi subacetat., f℥j,
Infus. ulmi, f℥viij,

kept constantly on the part.

September 28.—Patient presented; much improved. Treatment continued.

October 19.—The ulcers have entirely healed under the treatment, thus verifying our diagnosis. The specific remedies will, however, be continued for some time longer, until the poison is effectually controlled; or the ulceration may return. The patient's nose is very much disfigured, and at a future period, when she has quite recovered, we will make her a new nose by a plastic operation, taking a flap of skin from the adjacent parts. This is an ancient operation, and was invented and practised by the Chinese centuries ago. Tagliacozzi, an eminent Italian surgeon, by an ingenious but tedious process, took a flap from the inner side of the patient's arm, over the flexor muscle, the hand being fixed to the top of the head and the arm firmly held in position by apparatus, until the skin adhered to the edges of the gap, which had been freshened previous to stitching on the new integument. This was subsequently modified by the German surgeons, but the original Chinese method is the one now generally preferred.

Congenital Hypertrophy of Left Hand and Arm (*Australian Medical Journal*, January, 1872).—A remarkable case of this affection is recorded by Mr. P. H. MacGillivray, of Bendigo. The disproportion between the two arms was but slight at birth, but at the age of twelve months the left arm began to grow rapidly, the whole limb from the shoulder becoming much enlarged, to some extent in point of length, but chiefly in thickness. The first, second, and third fingers were enormously hypertrophied, the hypertrophy involving all the structures. The child could use the arm and all the fingers, but could not lay hold of anything. As the most likely way of arresting the growth, Mr. MacGillivray ligated the brachial artery high up. This was accomplished successfully, and a month afterwards no increase had occurred. The hypertrophied fingers were then amputated with good result, the arm and remaining fingers ceasing to grow, and the child obtaining good use of the latter. Photographs of the limb accompany the paper.

The American Medical Association.—Permanent members who have not paid their assessment will please notice: "Any permanent member who shall fail to pay his annual dues for *three successive years*, unless absent from the country, shall be dropped from the roll of Permanent Members."

PHILADELPHIA
MEDICAL TIMES.
A WEEKLY JOURNAL OF
MEDICAL AND SURGICAL SCIENCE.

The Philadelphia Medical Times is an independent journal, devoted to no ends or interests whatever but those common to all who cultivate the science of medicine. Its columns are open to all those who wish to express their views on any subject coming within its legitimate sphere.

We invite contributions, reports of cases, notes and queries, medical news, and whatever may tend to increase the value of our pages.

All communications must bear the name of the sender (whether the name is to be published or not), and should be addressed to Editor Philadelphia Medical Times, care of the Publishers.

PUBLISHED EVERY SATURDAY BY
J. B. LIPPINCOTT & CO.,
715 and 717 Market St., Philadelphia, and 25 Bond St., New York.

SATURDAY, NOVEMBER 2, 1872.

EDITORIAL.

MORTALITY RETURNS.

BY the courtesy of Mr. George E. Chambers, Registrar of the Board of Health, we are enabled each week to place before our readers the latest available returns of the causes of death in the persons interred within the city. Although we are well aware that these documents are open to many criticisms, we think they have a certain value in themselves, and that it is even possible, from the comparison of a long series of them, to arrive at conclusions of some importance. Thus, a very casual view can distinctly trace the influence of meteorological changes, in the varying proportions of the different classes of disorders, not only in the same year, but in a succession of years. During epidemics, their rise and decline may be marked with something like accuracy, and by the apposition of their statistics with those of temperature, rainfall, prevailing winds, etc., especially when the observations extend over long periods, information has been gained as to the circumstances favoring or retarding these scourges.

The great difficulty with these statistics lies in the vagueness and inaccuracy with which so many of the special returns are made. Not only the ignorant among regular practitioners, or quacks, but many of the really scientific in the profession, regard the death-certificate as a document issued rather to prevent foul play,—as a sort of permit to the grave-digger to break the ground,—than as a responsible expression of opinion as to the exact cause of death. Thus we find, in one week's return, deaths reported as due to "child-bed," "dropsy," "disease of lungs," "disease of liver," "hemorrhage," "inanition," "insanity," "malformation," "suffocation," "tumors," "ulcers." Such vagueness wholly destroys the value of the reports.

As to positive ignorance, and inaccuracy, we may, perhaps, believe that the errors in one direction would be likely to offset those in another, so that about as many cases of smallpox, for example, would be unrecognized, as other cases mistaken for it and so reported.

Much has to be done in every way to improve the value of these returns, and we trust that the attention of our medical societies and statisticians will before long be drawn to the matter more effectively than heretofore. We would ask our readers to use their influence, wherever possible, in the interest of science, to bring about a change in this respect.

A short time since, in New York City, a most absurd attempt was made to show, from the mortality returns, the advantage of homœopathy, in that a smaller proportion of deaths was reported by the adherents of that system. The following extract from the proceedings of the New York County Medical Society will expose some of the fallacies of this comparison :

"Dr. F. V. White, referring to a correspondence which lately appeared in *The Medical Record*, asked the privilege of inquiring of Dr. Russell (the Register of the Bureau of Vital Statistics of the New York Health Department) what authority the homœopaths had for asserting that they have a less percentage of mortality in their practice than the regular profession.

"Dr. Russell said the gentleman had used the privilege, which is open to all, of examining the books of his office, and had, moreover, employed the services of a couple of clerks for two months. Nevertheless, in the statements he had made at the meeting of some homœopathic society, he had distorted facts, and administered untruths in other than homœopathic doses. As an illustration of the way he had conducted his examination, Dr. Russell mentioned that he had commenced by placing homœopathic physicians in good standing in one list, and in the other embraced ourselves with all the quacks, abortionists, and irregular practitioners.

"Dr. Jacobi remarked that since the statement referred to did not make any estimate of the comparative numbers of patients treated by the two classes of physicians mentioned, the statement of comparative mortality was of no value whatever. The whole affair reminded him of something which occurred not long ago; when a physician had said that Dr. Jacobi killed a great many more babies than he did—*ergo*, he was the better doctor of the two. He (Dr. Jacobi) had been uncourteous

enough to remark that perhaps Dr. Jacobi 'killed' more babies than this physician referred to treated altogether.

"Again, no account appeared to be made of the fact that the great multitude of pauper patients which are found in our numerous public hospitals and dispensaries are under the care of regular practitioners, whereas the homœopaths have not a single hospital containing patients of this class.

"Dr. Russell explained that the person who made this estimate had professed to exclude from his list all hospital and dispensary physicians; but as very many of our best physicians hold hospital and dispensary appointments, and as it is a matter of impossibility to say what patients are treated in the public and what in the private practice of these gentlemen, the valueless character of the estimate is apparent. Furthermore, the author of the homœopathic circular estimates an average of 30.89 deaths to each regular physician, whereas he doubted very much if there is a single regular physician in the city who had as many as thirty deaths in his private practice during a year; the number, even among some of our eminent men, being much below that number.

"One of the older members of the Society, in relating 'what he knew about signing death-certificates,' said that he had found that in his neighborhood the homœopaths were in the habit of getting rid of cases which were likely to terminate fatally, and of shifting the responsibility of signing a death-certificate upon the shoulders of some regular physician. During the years in which he had practised in the country, he had accumulated on his books over three hundred cases of this sort, which had been turned over to him by the homœopathic practitioners around him."

THE EPIDEMIC AMONG HORSES.

THE daily papers have for several days been filled with accounts of a disorder which, apparently originating in Canada, has spread over the northern and eastern portions of this country, affecting the horses so universally as to produce a vast degree of inconvenience and loss. Over 18,000 horses are said to be too ill to work, in New York City alone. Probably these lines will not be in print before the epidemic (or *epizootic*, as the newspaper purists have it) will have spread southward as far as this city. It seems to be a sort of influenza, and the mortality from it is not very great. Rest, fomentations to the throat and legs, sweating, and anodynes, seem to be the most rational elements of the treatment, and to have had the best results.

We have as yet seen no mention of mules or horned cattle being attacked with this disorder; but the proportion of mules to horses kept in the more northern States is so small, that allusion to them would perhaps be omitted for this reason. If mules are insusceptible to it, we can scarcely understand why they could not have been temporarily substituted for horses in the more important uses of business and necessity.

Some of the newspaper reports speak of the disease as affecting the human species, apparently by contagion; but these statements are doubtful. We fear that experience will enable us to judge but too well of the accuracy of our advices from the districts already suffering under this real scourge.

AN EXTRAORDINARY SCENE IN COURT.

ON the 15th of July last, a most extraordinary scene, and in our opinion a most barbarous and revolting exhibition of judicial cruelty, took place at the Assize Court at Chelmsford, England. We quote the account of it given in the *Medical Times and Gazette:*

"A young and, as the newspapers express it, 'interesting-looking' married woman was arraigned for the wilful murder of her husband's first wife by poison. The deceased had died on October 10 last, and the prisoner, who was married only in December, was far advanced in pregnancy. The woman was in the dock, with a couple of brief intervals, for the space of seven hours, and bravely she bore the trying ordeal, conducting herself with as much ease and self-possession as any lady whilst dispensing the hospitalities of her own drawing-room. In the course of the afternoon, just after Sergeant Parry had cross-examined Dr. Stevenson relative to the presence of arsenic in the viscera of the deceased, and the Hon. G. Denman was commencing his re-examination, the prisoner, who had risen from her seat during the delivery of Dr. Stevenson's evidence, was led out of court, and the rumor spread that her confinement was imminent. Her speedy reappearance, accompanied by Mrs. Gilson, Finch, and Carter, reassured the court, and it was intimated to the judge that the trial had better proceed. It was evident, however, to skilled eyes, that the poor creature suffered from either true or spurious labor-pains. A couch was brought, and the examination of the expert was resumed. For the next hour or two the scene was ghastly in the extreme. Labor-pains recurred at one time every three or five minutes, the prisoner alternately reclining, sitting, and standing; the evidence meantime proceeding as if nothing had happened. At one time two medical men were with her in the dock at the same time, and it was evident that their cheery counsel revived the poor creature. At 5.30 P.M., the evidence for the prosecution being finished, and no evidence being forthcoming for the defence, the question arose what was to be done. Baron Martin offered to go on with the case till midnight if necessary, but it was represented by counsel

that the medical men were of opinion that the poor creature might be the better for a night's rest; so the trial was adjourned till next morning, and the excited spectators, among whom were a large number of unmarried females, dispersed. In the course of the evening the prisoner was delivered of a child; next morning the jury was discharged, and the trial postponed for three months. We suppose such a harrowing scene could scarcely have been avoided. What the consequences would have been had the trial proceeded, and either a verdict of guilty or of not guilty been pronounced, we cannot say. Happily, such another tragedy as this can rarely be enacted in all its details. Meanwhile the miserable woman is condemned to a further three months of suspense."

It seems as if comment on this would scarcely be necessary; and yet we cannot but think that, had such a scene been described as occurring in an American court-room, the foreign journals would have denounced it as a hideous outrage. Why the trial could not have been postponed for three months just as well before this public exposure of the poor creature's agonies as after it, we are not informed. If the actual pangs of labor are not to interfere with the progress of a judicial inquiry of the gravest moment, the patient being merely under suspicion, it does not seem as if any bar could exist to carrying out the extreme sentence of the law on a convicted person the moment that delivery had taken place. As the matter now stands, we must regard it as a grievous blot upon the vaunted civilization of England.

CORRESPONDENCE.

To the Editor of the Philadelphia Medical Times.

DEAR SIR,—There appears in your last issue a letter from Dr. Horatio C. Wood, Jr., in which he disclaims having had any personal or discourteous intention in his criticism on my views in regard to veratroidia and viridia. I accept the doctor's explanation, and would have been most happy to have allowed the discussion to have ended with his letter, were it not that he has again either *misread*, *misunderstood*, or *misrepresented* me.

1. In reference to the "*curious blunder*," now "*curious error*." The respective paragraphs in his "criticism" and in his letter to you are *self-contradictory*. However, the following extracts from the *Medical Record* will at once conclusively prove that the "*deduction* which he (Peugnet) attributed to me (Wood), namely, *that therefore, it is through these nerves that the alkaloids act on the intestinal tract*, that I objected to," has no foundation whatsoever, *either by word or by inference;* viz., from page 125:

"IV. That its action on the alimentary canal as an emetic and cathartic was due to its special action on the pneumogastric nerve, through the circulation, and not to any action as a local irritant, *is shown* by the fact that these were the last symptoms developed instead of the first—*also by the experiments of Prof. Horatio C. Wood with the veratroidia.*"

From page 129:

"That its action on the heart is through the sympathetic is shown by the experiments in which Prof. Wood divided the pneumogastrics; *these experiments further show that its peculiar action* on the alimentary canal *is through the pneumogastric nerves*, for there was no vomiting and purging except in the animals in which he had not divided the pneumogastrics."

2. In reference to the *viridia*, he says, "It is simply nonsense then to assert that the sedative powers of the latter alkaloid depended upon a contaminating portion of the former." I believe that every practitioner of medicine frequently combines remedies so as to either modify or increase the action of one or both, each one, or only one, acting *as an adjuvant* to the other. The same I believe has been found to exist in nature by higher authorities than either Dr. Horatio C. Wood, Jr., or myself. Therefore it is a needless task, and would be a waste of your valuable space, to enter into *an equation* to prove it.

3. In regard to *paralysis*, the doctor has now fully committed himself; and *I most emphatically deny that there existed any paralysis in a single one of either his or my experiments, with the viridia or veratroidia.* For every educated and careful observer is aware that Dr. Horatio C. Wood, Jr.'s indefinite expression, "all kinds of irritation," is not a sufficient indication of paralysis of the nerve-centres, *but merely indicates anæsthesia and loss of power.* As he only made use of the galvanic current on a few frogs, and since in every instance they responded to that stimulus, *he cannot rationally regard* that experiment, made exclusively on cold-blooded reptiles, as *proof presumptive of paralysis.* Whilst in every experiment made by myself, with the assistance of my friend Dr. Teats, the warm-blooded animals responded perfectly to the galvanic currents,—that is, endeavored to *remove the irritating pole from any portion of the body whatever to which it was applied*, whilst to "all other kinds of irritation" *they remained insensible.* Consequently I am correct in saying loss of power and anæsthesia, *whilst Dr. Wood is manifestly in error when he says paralysis.*

4. The non-use of the *cardiometer* is again a source of annoyance to him; for he says, "Dr. Peugnet makes a vital mistake in supposing that the use of the cardiometer or some similar instrument is not necessary to the experimental study of the circulation." The doctor *is again in error here*, for I accepted his views in regard to the action of veratroidia on the circulation, also *as to the action of Bullock's so-called pure viridia*, claiming that it was the combined action of the alkaloids. But in reference to my pure tested viridia, I quote what I did say, from page 473 *Phila. Med. Times*, viz.:

"He also objects to my conclusions in reference to the

circulation, as I did not make use of the cardiometer. I did not deem it necessary; for, as he admits that 'there was no slowing of the pulse' in my experiments with the viridia, its use was not necessarily indicated."

Furthermore, the following experiments are conclusive:

"XXII. I took gr. ¼ dissolved in acidulated water; at the end of one hour, no perceptible effect.

"XXIII. I took gr. 1 in capsule, P. 64; 25 min. P. 78; 35 min. P. 64; 55 min. P. 64; 60 min. drank a small glass of ale; 70 min. P. 64; there was no other effect perceptible, unless a pleasant muscular exhilaration and tension."

5. As Dr. Samuel R. Percy has not disputed my views in regard to his so-called exhausted resinoid of veratrum viride, and, *what is more, has accepted them as correct*, I doubt the *right and even the propriety* of Dr. Horatio C. Wood, Jr.'s saying "*especially as my results are in strict accord with those of previous experimenters*," particularly as *he was the first to make physiological experiments with viridia.*

I consider the discussion closed with this reply, to make which I was entitled, both by courtesy and usage.

EUGENE PEUGNET.

NEW YORK, October 18, 1872.

CASE OF POISONING BY ACONITE.

EDITOR PHILADELPHIA MEDICAL TIMES:

DEAR SIR,—The following case may be of interest to your readers. Miss C. D., æt. sixty-five, weight about two hundred and eighty pounds, took by mistake f℥j of tinc. aconite root, at seven o'clock P.M. The mistake was discovered a quarter of an hour afterwards, and she drank freely of milk and eggs. At eight o'clock a physician arrived and gave sulphate of zinc, which in about twenty minutes caused her to vomit freely. There was great numbness in all the extremities, and in an hour or two a terrible choking sensation. Pulse irregular, and sixty per minute.

At 10.45 P.M. her pulse was imperceptible, and she was in a very profuse cold perspiration; there were slight convulsions. Her surface felt like that of a dead person.

At 11.15 P.M. she was apparently dead, so far as respiration or circulation could be discerned; yet she kept some part of the body moving, and in less than an hour began to rally. By midnight her pulse was perceptible; she continued to improve, and by nine o'clock next morning she was quite free from all symptoms of poisoning, although feeling very weak. She made a good recovery, but died in three weeks from the effect of a carbuncle, or rather a large sloughing phagedenic ulcer, which had developed itself across the lumbar and sacral region before she took the aconite.

Stimulants (brandy) and external heat constituted the treatment. Very truly,

G. COX, M.D.

SOUTH HADLEY FALLS, MASS., October 17, 1872.

REVIEWS AND BOOK NOTICES.

OVARIAN TUMORS: THEIR PATHOLOGY, DIAGNOSIS, AND TREATMENT, ESPECIALLY BY OVARIOTOMY. By E. RANDOLPH PEASLEE, M.D., LL.D., etc. New York, D. Appleton & Co.

Another work on ovariotomy! Good heavens! where is this to end? What with ovariotomy made easy, with these ready methods *in usum Delphini*, every recent graduate will be making the major incision and spaying his patients on the mildest provocation. We say this advisedly, for at this very moment there is lying before us a pamphlet on—dare we give it?—the extirpation of the ovaries for endometritis; nay, *with a case in point.*

Despite our well-founded fears, we honestly confess that the work whose title heads this notice was very much needed. It shows prodigal industry, and embodies within its five hundred and odd pages pretty much all that seems worth knowing on the subject of ovarian diseases. To the superficial reader it may appear the height of audacity for an author with only twenty-eight cases of ovariotomy to his name, to lay down the law in the face of men who have had almost as many score. But this very paucity of his own statistics has, very fortunately, driven him to do what no other ovariotomist has yet done. Some have given the history of their cases,—their individual experience,—liable as all such experience is to be warped by hobby or partisanship. Others, like Kœberlé, of Strasburg, have favored the profession with what may be termed autobiographies, in which they have cried "Eureka!" blown their own trumpets, and given the view-halloo on every possible occasion. But Prof. Peaslee, taking a broader scope, ranges over the whole domain of the subject. Comparing his own experience with that of others, he has winnowed and sifted the whole of all chaff, and has given the clean grain to the reader. The frontispiece tells the whole tale; it is a portrait—not of the author, but—of Ephraim McDowell, the father of ovariotomy.

Like old Gaul, this excellent book may be divided into three parts; and, to pursue the simile, we predict that, like old Gaul, it will give its hero a triumphal procession along the Via Sacra up to the threshold of Tarpeian Jove. Part first discusses the "normal anatomy, pathology, and treatment of ovarian tumors—excepting ovariotomy." (We give the quotation-marks, not wishing to be held responsible for the phrasecology.) Part second sketches the history of ovariotomy; whilst the third part is devoted to the subject of ovariotomy proper.

Each is treated exhaustively, and each will be read with pleasure and with profit; but the one on which the general reader will linger is that on the history of ovariotomy. With its lights and its shades, its friends and its foes, its converts and its perverts, how like a romance it reads! With all opposition gone, with the operation legitimized, tame will its future be. But we forget: there lingers on one Jacobite, one adherent of the ancient dynasty. Consistent to the last, this venerable Cassandra, luckily not of us, but *in partibus*, holds out against the pitiless logic of facts. Year by year this brave old man stands up in his seat and utters his rugged protest. "Retire tois! retire tois! franc traitre Anglois;" so sang the troubadour to a Briton of the past, and so say we to thee, for thy days are of the past, and thy dreams likewise.

One patriotic pang—we still feel its twinges—prodded us as we read this history. Ovariotomy first took root in our own soil; tenderly was it nursed by our own countrymen into a comely plant. But, alas! the fruit has been plucked by strangers. British surgeons and

British works are now the standard authorities. Think of Clay of Manchester, with one hundred and eighty-two cures out of two hundred and fifty operations; of Wells, just beginning his fifth series of a hundred each; of Keith, cooped in a provincial town, saving eighty-one out of his first hundred, and thirty out of his next thirty-six cases. A murrain—but no, the thought is too uncharitable. After this we can no longer maintain idyllic relations with perfidious Albion.

Of course the old stock-story of the Hungarian sow-gelder and his amorous daughter is given—what work on ovariotomy is considered complete without it? This thrice-told and thrice-apocryphal tale we forgive the author, but hardly such rasping hybrids as "The olygocystic cystoma ovarii," and its kin. But the evil spirit of hypercriticism is upon us, and we end, not, however, without one Parthian shot. In the dedication to this book, Spencer Wells's name is coupled with that of Ephraim McDowell. Why is this? Why, instead, was not the name of the first of living American ovariotomists? Single-handed, Atlee has fought his way *per aspera et ardua* up to fame and honor. He it is who legitimized the operation at home and abroad. True, Wells has the numerical advantage; but Atlee and Clay had paved the way for him, and he entered the lists with a flourish of trumpets, with heralds and pursuivants, and with the plaudits of an admiring throng.

A Manual of the Diseases of the Eye. By C. Macnamara, Surgeon to the Ophthalmic Hospital; Professor of Ophthalmic Medicine in Calcutta Medical College. Second Edition. Small 8vo, pp. 620. Philadelphia, Lindsay & Blakiston.

The first edition of this work, published by Churchill & Sons in 1868, took its place in medical literature as the most complete, condensed, and well-arranged manual on ophthalmic surgery in the English language. Arranged especially for medical students, it became, however, the work of reference for the busy practitioner, who could obtain nearly all that was best worth knowing on this subject, tersely stated, and easily found by the aid of the excellent marginal notes on the contents of the paragraphs.

The second edition, now before us, differs from the first only in the introduction of new material rendered necessary by the advancement in ophthalmic surgery, and in the rejection of views that have been superseded. The general appearance of the book remains unaltered, and it will not be less welcome than its elder brother, with its good illustrations, compact and portable size, and flexible covers.

A few of the chromo-lithographs have been omitted, and we think with benefit to the progress of truth. The most important improvements that have taken place in ophthalmic science are now presented, and the second edition, with these marks of the careful hand of the author, may still be regarded as the most convenient and valuable manual on the diseases of the eye within the reach of the student or general practitioner.

New Treatment of Venereal Diseases and of Ulcerative Syphilitic Affections by Iodoform. Translated from the French of Dr. A. A. Izard, by Howard F. Damon, M.D. Boston, James Campbell, 1872.

The little volume before us is a neat monograph of seventy-three pages. Dr. Izard endeavors to prove by a number of experiments made in the wards of the Hôpital du Midi, Paris, that iodoform as a topical remedy constitutes the best dressing known in certain venereal lesions. This substance he used in all of the ulcerative processes of venereal disease, and found it to be of especial value in the treatment of chancroids and their buboes. Clinical notes of some twenty cases of chancroid and bubo are given, together with the treatment and results, which certainly appear to be highly satisfactory. The author's conclusions may be briefly summed up as follows: That iodoform acts more promptly in healing ulcerative venereal manifestations than other remedies usually employed. That, in the treatment of soft chancre, iodoform is in some sort a specific, from the promptness with which it produces cicatrization without pain. That, in the treatment of non-syphilitic buboes, iodoform can be employed in the form of an ointment as a resolvent, during the early stage, with more success than the blister and tincture of iodine. That iodoform acts not only as a topical agent, but still further as a local anæsthetic. We commend a reading of this work to those interested in the treatment of venereal lesions, with a view that the merits of iodoform be thoroughly tested, and that it may be assigned its proper place among therapeutical agents.

The Science and Practice of Medicine. By Wm. Aitken, M.D. Edin. Third American and Sixth London Edition. 2 vols. 8vo, pp. 1056, 962. Philadelphia, Lindsay & Blakiston, 1872.

This third American edition attests the demand which will always meet a thoroughly good work. The title-page informs us that it is "greatly enlarged, carefully revised, and many portions rewritten, etc.," with additions by its able editor, Dr. Clymer, of New York. In what the new differs from the older editions we have not the space to minutely notice, but a more complete book of reference and compendium of its subject it would be difficult to find. The American editor contributes fourteen new articles and numerous fragments. The treatment of disease, also, appears to have received more attention, vagueness on this topic having been the one vulnerable point of the earlier editions. We have also the nomenclature of diseases authorized by the Royal College of Physicians, to which the present work conforms, and though not unexceptionable perhaps, still, something definite in the way of nomenclature is better than the magnificent vagueness which a study of our weekly death-returns in the original reveals. We feel sure that "Aitken" will in the future prove as true a friend as ever, and hold its rank among the indispensable books.

GLEANINGS FROM OUR EXCHANGES.

M. Ollier's Occlusive Dressing (*Med. Times and Gazette*, August 3, 1872).—In the last two numbers of the *Lyon Médical*, M. Poncet brings forward some new illustrations of the great advantages attending the employment of M. Alphonse Guérin's mode of dressing wounds with cotton, in association, as recommended by M. Ollier, with the silicate bandage, so as to constitute what the latter surgeon terms *occlusion immobile*. The object of these papers is, however, not to set forth the general advantages of this plan, which have now been made pretty widely known, but to show its great utility in warding off those hospital complications which have so often excited terrible effects,—pyæmia, erysipelas, and hospital gangrene. During the last half-year more than one hundred of the *bandages ouatés-silicates* have been applied in M. Ollier's ward (containing one hundred patients) to every wounded surface, and not one of these patients has succumbed to pyæmia or been attacked by erysipelas. The bandage in these cases has been kept on for a week or a fortnight, and sometimes for three or more weeks; all accidents from such retention being guarded against by paying attention to

the pulse, temperature, and feelings of the patient. The bandage has had to be removed wholly or in part in a few cases, on account of the imperfect way in which it had been applied. In all cases, wherever possible, such removal has not been performed in the wards where the other patients were; the wound being also kept exposed for the shortest possible time; and the quite new, fine cotton taken only from the parcel as wanted. The portion of this brought in immediate contact with the wound has usually been impregnated with carbolic acid or alcohol. In this mode of dressing, the minutest details must be considered, and the great object of exclusion of air can only be attained by the superposition of several thick layers of cotton, which must reach very far beyond the surface of the wound. Thus, after an amputation of the leg, it does not suffice to cover the stump with the silicated bandage, but this must also comprise the thigh and the trunk. Without such precautions it becomes a bad mode of dressing, retaining pus which has undergone change from action of the air in contact with the wound. Before the bandage is applied, as many arteries as possible should be secured, and for this purpose the wound should be left exposed for fifteen to twenty minutes.

M. Poncet gives various details concerning the chief classes of wounds which were treated during this period; and he observes that if these cases were to be taken as conclusive, this procedure might be pronounced an absolute preservative against these complications. No case of pyæmia, erysipelas, or hospital gangrene was observed in cases so protected, although the last two affections prevailed in the ward. However, he wishes no exaggeration upon the subject, and observes that while failure will occur wherever the bandage is imperfectly applied, even when its adaptation is perfect, we only place the wound in the very best condition for healing by preventing complications from without. Its healing, however, of course depends also upon other circumstances; it is a means especially adapted for hospital practice, and is not required in cases treated in localities where the air is not likely to be contaminated. The cases M. Poncet relates were also treated in winter, but in summer the dressing may have to be removed every five or six instead of every fifteen or twenty days.

Period of Incubation of Typhus, Relapsing Fever, and Enteric Fever (*The Practitioner;* from St. Thomas Hospital Reports, 1871).—Dr. Murchison remarks that the period of incubation of contagious diseases, or the period that elapses between the entrance of the contagion into the system, and the first manifestation of its presence there by symptoms, is not merely a matter of scientific interest, but has many practical bearings, and lies at the bottom of many of the most important sanitary questions. Cases throwing light on the latent period of a disease are of a threefold nature: 1. Those in which there has been a single limited exposure to the contagion. 2. Those in which there has been a protracted exposure, both limits of which are known. 3. Those in which there has been a protracted exposure, of which only one limit is known. Either the exposure has persisted from the commencement up to the date of the patient's seizure, in which case it can only be said that the period of incubation has not been less than that interval, or an interval of time has elapsed between the cessation of a protracted exposure and the commencement of symptoms, and then it can only be said that the period of incubation has not been less than that interval. The first class of cases are of course the best.

Dr. Murchison gives the data on which his conclusions are founded, and states that he has been engaged for many years in collecting them. In regard to typhus fever, he believes he has ascertained: 1. That the period of its incubation varies in duration in different cases. 2. In a large proportion of cases it is about *twelve days*. 3. In exceptional cases it is longer than twelve days, but it rarely, if ever, exceeds three weeks. 4. In many cases (one-third or more) it is less than twelve days, and occasionally there is scarcely any latent period, the symptoms commencing almost at the instant of exposure to the poison. In regard to relapsing fever, the facts obtained are somewhat less satisfactory, but they point to the following conclusions:— 1. That the period of incubation of relapsing fever is not a fixed period, and is even more variable than that of typhus. 2. It is, on the whole, shorter than that of typhus. In not one of the nine cases in which it was accurately determined did it exceed *nine days*, and in a considerable number of cases it did not exceed five days. 3. Occasionally, as in typhus, there is scarcely any latent period at all, the symptoms commencing almost immediately after the first exposure to the poison.

In regard to typhoid or enteric fever, Dr. Murchison states that reliable facts bearing on the period of incubation of enteric fever are even more difficult to obtain than illustrations of the latent period of typhus or relapsing fever; his conclusions are: 1. That the period of incubation of enteric fever is most commonly about *two weeks*. 2. Instances of a longer duration appear to be more common than in typhus or relapsing fever, though in cases where it has been reported to extend over many weeks or months it may be doubted whether the disease has not had an independent origin. 3. The period of incubation is often less than two weeks, and, as in typhus and relapsing fever, it may not exceed one or two days.

Lifelike in Death.—Rossbach, in a late number of *Virchow's Archiv* (Band li.), has given an interesting account of numerous cases of sudden death on the fields of Beaumont and Sedan, in which the bodies of those killed retained the position and the expression of face present just before death. In one case, a group of six French soldiers were killed by the explosion of a single shell as they were breakfasting in a slight hollow. The shell had struck one of them, sitting in the middle, full in the back, where it was partially lodged; the fragments had torn away his thighs and buttocks, and killed his comrades. From one of them the skull was carried off, while the face still retained the expression of laughter at the joke of a companion. The next one to him still held, delicately raised to his lips, between the forefinger and thumb, a tin cup from which he was about to drink, when the explosion had taken off the whole of the upper part of the face and head. The close manner in which they were seated together had prevented the bodies from falling after the lapse of twenty-four hours. In another case, a soldier, shot through the breast, lay half reclining on one side, with the photograph of his wife or lover held up straight before him. Rossbach cannot admit that in such cases the nervous centres must necessarily be injured, nor that death must have been instantaneous. Rigor mortis must have set in between the last moment of life and the first of death.

Dr. J. H. Brinton, in an interesting article on this subject, published in the *American Journal of Medical Sciences* for January, 1870, page 87, relates a number of similar cases which were observed during the late war in this country.

Fatal Peritonitis from a Single Vaginal Examination (*Aerztl. Literaturblatt*, June–July, 1872).—During the discussion of several melancholy cases of suppurating uterine fibroids in the surgical society of Paris, Verneuil related a case where a single examination per vaginam was followed by the death of the pa-

tient, whereupon Cillette reported the case of a woman who was admitted to the hospital in 1862 with prolapsus uteri, who died in two days after a vaginal examination, from acute peritonitis.

She had suffered with a copious hemorrhage for a year. After three days' rest in the hospital, a vaginal examination was undertaken; a speculum was not used, and slight prolapsus uteri was recognized. On the following day an intense peritonitis supervened, with all its symptoms strongly marked, and in forty-eight minutes [hours?] after the inception of the disease the patient was a corpse. The post-mortem revealed besides the lesions of peritonitis a thick pseudo-membranous mass in the uterine adnexa of the left side, congestion of the left tube and ostium abdominale, redness and swelling of the left ovary, a cavity filled with pus and false membrane between the ovary and the tube, and a small subperitoneal abscess. These lesions of the ovary and its neighboring parts formed the points of departure for the peritonitis, as the uterine lining was affected only with fungous softening. Nélaton had previously diagnosticated in this subject a latent affection of the uterine adnexa. The exploration, simple as it was, excited a congestion which extended to the tubes and awakened a fatal peritonitis.

Récamier has made two post-mortems on cases where death followed in forty-eight hours after washing out the uterus. In both these cases former symptoms of latent disease had been present. Such sad instances must remind the physician of the caution to be adopted in the case of patients who complain of pain in the iliac region, which is indicative of latent disease, and must exemplify that the dangers of instrumental examination are greater than most physicians are inclined to believe.

Spina Bifida cured by Repeated Tapping and Pressure.—At the meeting of the Lisbon Society of Medical Sciences, on February 17, Dr. Camara Cabal communicated a case of spina bifida which he had treated successfully.

The patient was a child, aged twenty-five days, which had in the lumbo-sacral region a swelling forty centimetres in circumference, seventeen in vertical, ten in transverse diameter, and six in depth. It fluctuated, was transparent like a hydrocele, and appeared to contain not only a fluid, but some solid body. Pressure on it produced no convulsions, nor was there any paralysis or symptoms denoting lesion of the cord. It was therefore concluded that the tumor consisted exclusively of a hernia of the meninges, filled with fluid.

On November 29, it was tapped with a Dieulafoy's trocar, and 400 grammes of transparent yellow fluid, containing an abundance of albumen, were removed. Compression was applied by means of adhesive plaster. No symptoms followed the operation, beyond some vomiting and loss of appetite. Some days later, the tumor having enlarged, 250 grammes of liquid were removed; and on December 14, 425 grammes. The defect, which was found to be in the situation of the fourth and fifth lumbar vertebræ, was gradually diminishing. On a fourth and fifth occasion puncture was performed at intervals of some days, the quantity evacuated being respectively 175 and 125 grammes, the fluid being more highly albuminous than before. After the last two operations there was some meningitis, which yielded to ordinary remedies. The child made a good recovery.

Spina Bifida cured by Injection (*British Medical Journal*, June 15, 1872).—Dr. Morton, of Glasgow, records two cases in which spina bifida was cured by injection. The procedure may be shortly stated to consist (1) in performing two tentative tappings with a grooved needle, with an interval of four or five days between the two. (2) The tumor is tapped with a small trocar and canula, allowing about half the contents of the sac to escape, and about a drachm of a solution of iodine in glycerine is injected. The after-treatment consists in dressing with some bland substance, as oil or lard, cleanliness, and care, so as to avoid local injury or irritation. Prevention of the complete escape of the cerebro-spinal fluid he believes to be of the greatest importance; and in the second case he brushed the wound over with collodion, which answered admirably. The presence of this fluid is essential to the functional, if not the structural, integrity of the spinal cord and brain; and if it be allowed to drain away, the child speedily succumbs.

Subcutaneous Injection of Ergotin in Varix (*Berliner Klin. Wochenschr.*, March 4, 1872, and *Brit. Med. Journal*, April 27, 1872).—Having observed the records of good results following the subcutaneous injection of ergotin in cases of aneurism in the hands of Von Langenbeck, Schneider, and Dusoit, Dr. Paul Vogt, of Greifswald, was led to try the remedy in varix of the lower limb. The first patient on whom the experiment was made was a man aged sixty, who had suffered for several years from extensive varices of the leg. A solution of two grammes of ergotin was made in seventy-five grammes each of spirit of wine and glycerin, and a quantity containing twelve centigrammes of ergotin was injected at the proximal end of a varix more than two inches long, and as thick as a little finger, lying over the tibia. The injection was repeated every second day. In eight days the varix could not be seen, and in six weeks no trace was left. During the treatment the patient went about as usual. Another varix, of the size of a hazel-nut, lying on the outer side of the calf, was treated in a similar manner with the same result. At the point where the injection was made there was some hard circumscribed infiltration, which gradually disappeared. Several other patients in the Greifswald Hospital, some of them with very large varices, have been treated with the subcutaneous injection of ergotin with a surprisingly good result. Dr. Vogt believes that the ergotin causes contraction of the muscular coat of the arteries, so that the flow of blood into the dilated vessels is hindered; that it also produces contraction in the veins, and that the local infiltration following the injection may have some effect by the compression which it exercises.

Subcutaneous Injection of Ergotin in Uterine Fibromyomatous Tumors.—Dr. Hildebrandt, of Königsberg (*Berliner Klin. Wochenschr.*, June 17, 1872), has used subcutaneous injection of ergotin in nine cases of uterine fibroid. He employs a solution of three parts of aqueous extract of ergot in 7.5 parts of distilled water and the same quantity of glycerin. Langenbeck's solution he has found to produce pain, on account of the alcohol contained in it; while the use of the solution which he recommends is unattended with pain, and is not followed by suppuration. Somewhat tender indurations are now and then left for some time at the seat of injection. In general, however, the treatment is unattended with inconvenient results. The lower part of the abdomen is more sensitive to the puncture and the injection than is the neighborhood of the umbilicus. At the time of menstruation, and for a few days before and after, slight bleeding takes place from the punctures. The general result of the injections has been a diminution of the tumors; and Dr. Hildebrandt accounts for this by supposing that the increased compression produced by the ergot interferes with their nutrition, and leads to their degeneration and absorption.

The city government of Boston has purchased a site on Pine Street for a smallpox hospital.

MISCELLANY.

A Horrible Story from Paris (*Food Journal*, October 1, 1872).—Three men have been arrested, and are now in charge of the police, for manufacturing and selling *saucissons* (large, or "German" sausages) of the most disgusting composition. Perrin, the chief culprit, lived in a house at Levallois-Perret, a commune just outside the walls of Paris, adjoining Neuilly. A very bad smell frequently invaded the streets, and the inhabitants became alarmed, for the house had a terrible reputation, it having been formerly inhabited by a butcher who was executed for murder and for having sold some of the flesh of his victims for human food. The report was soon current that Perrin, who was a sausage-maker, had discovered the remains of buried communists, and was using them in his trade. The storm was gathering over the fellow's head, when a man named Bonnin appeared before the commissary of police of the place, and declared that he had purchased of Perrin three quintals of sausage, to sell by retail to the masons and fishermen of the neighborhood, and that he had been grossly defrauded, as the meat was in a horrible state of decomposition. The manufacturer and his sausages and meat were immediately seized, and the latter was in such a condition that the persons called in to inspect it were seized with serious vomitings. It turned out on inquiry that these dreadful sausages were composed of the flesh of dogs, cats, and other animals collected by "chiffonniers" in the streets of Paris.

M. E. Decaisne made an important communication to the Académie des Sciences, June 15, 1872, of which the following is an abstract:

"It appears by the figures given by the author for the principal States of Europe, that in the triple point of view of the fecundity of marriages, of the number of births, and of the excess of births over deaths, France occupies the last place in Europe. In Prussia, for every one hundred marriages there are four hundred and sixty children; in France, only three hundred. In Prussia, the number of births annually, in proportion to the population, is 3.68 per cent.; in France, only 2.55. Lastly, the excess of births over deaths in every million of inhabitants is, in Prussia, thirteen thousand three hundred, while in France it is only twenty-four hundred. From these figures we learn that the population of France will not double itself in less than one hundred and seventy years, while that of Prussia will double itself in forty-two, that of Great Britain in fifty-two, and that of Russia in sixty-six years."

Desire of the Dying for Rest.—A writer in the *Galaxy* says, "In their last hours men and women want physical rest and ease above aught else; and I have known instances in which the replies of persons near their dissolution were in such sharp contrast to inquiries made of them as to become positively grotesque. I was present when an acquaintance, having been struck down in the street by a falling chimney, was carried home in a dying state. As soon as he had recovered consciousness, his wife, half frantic with terror, leaned over the sofa on which he lay, and said, 'Oh, my darling, do you really love me?' The response was, 'Yes, if you will pull off my boots;' and these were his last words. A gentleman, long ill of a wasting fever, had reached that condition of rest which generally heralds the great transformation. His betrothed, who had devotedly nursed him, said, 'Dearest, do you die happy?' 'I should,' was the answer, 'if that infernal fly wouldn't bother me,' and spoke no more. 'Wouldn't you like to see your father?' inquired a doting mother of her only son, as his life was ebbing fast. 'Of course I should; but I'd rather have my face washed.' Such words, apparently harsh and unfeeling, come from persons of natural sensibility and tenderness, because in their dying hour the desire for material comfort often crowds out every other consideration."

Discoloration of Chinese Children (*The Practitioner;* from Report of the Pekin Hospital, by Dr. John Dudgeon).—We have often observed over the sacral region of new-born children, and during infancy, but never once in adult life, a peculiar bluish mark of considerable size. The Chinese are all familiar with it, and call it, *par excellence*, the "black" (*tsing*). From the general belief in metempsychosis, old women assert that it is caused by the dead person lying upon the cash which is placed in the coffin of the deceased. Money is added by the friends and others, we know, in such circumstances, with the view of giving wealth to the departed in the other world. Or this may probably have originated in the older idea of placing gold and other metals in coffins to prevent putrefaction. We have obtained no physiological explanation of this mark. It is not a "mother's mark."

A So-Called Home-Made Disinfectant.—The following paragraph is going the rounds of the press: "Dissolve a bushel of salt in a barrel of water, and with the salt water slake a barrel of lime, which should be wet enough to form a kind of paste. For the purpose of a disinfectant, this home-made chloride of lime is nearly as good as that purchased at the shops and drug-stores. Use it freely about sinks, cellars, gutters, and outhouses, and in this way prevent sickness, suffering, and expense." Such a mixture does not form what is commonly known as chloride of lime. A little chloride of calcium—an entirely different compound—is formed; but the latter has no disinfecting powers, and its preservative qualities are about on a par with those of common salt. The directions are entirely worthless.

Artificial Eyes.—A French paper gives a detailed account of the manufacture of false eyes in Paris, from which the curious fact appears that the average sale per week of eyes intended for the human head amounts to four hundred. One of the leading dealers in this article carries on the business in a saloon of great magnificence; his servant has but one eye, and the effect of any of the eyes wanted by customers is conveniently

tried in this servant's head, so that a customer can judge very readily as to the appearance it will produce in his own head. The charge is about ten dollars per eye. For the poor there are second-hand visual organs which have been worn for a time and exchanged for new ones; they are sold at reduced prices, and quantities are sent off to India and the Sandwich Islands.

Appointments, etc.—Dr. J. K. Bauduy, Physician to the St. Vincent Asylum of St. Louis, has received an appointment to the Chair of Psychological Medicine in the Missouri Medical College. Dr. John H. Callender, Superintendent of the Tennessee Asylum, is to lecture upon "Insanity; its Causes and Treatment," in the Medical Department of the University of Nashville. Dr. C. H. Hughes has resigned the position of Superintendent of the Missouri State Asylum. He will give his special attention to the treatment of diseases of the nervous system, in St. Louis. Dr. T. A. Howard is appointed to the Superintendency made vacant by the resignation of Dr. Hughes.

The British papers report the case of a Miss Hough, aged fifty-five, who died a quarter of an hour after being stung by a bee. The deceased was in her garden inspecting her bees, when she suddenly called to the gardener that she had been stung. The gardener, on coming to her, removed a bee from her hair. She became unconscious, and died in a quarter of an hour. The body was examined, but the only lesion was a good deal of discoloration behind the ear around the sting. The physician who made the autopsy said there was but one sting, and that he thought death was caused by shock to the nervous system. Her brother stated that the deceased, in 1870, was stung by a bee, and that she became unconscious and remained so for two hours. The jury returned a verdict of "Death from Syncope, accelerated by the Sting of a Bee."

English Hospitals in Paris.—There are at present two English hospitals in Paris. One is Galignani's well-known hospital for "English and Americans," founded in 1865 by Anthony and Wm. Galignani, with an endowment of 500,000 francs. It contains twenty beds for each sex, is well situated, surrounded by a beautiful garden, and provided with all necessary apparatus.

Lately, Richard Wallace, a wealthy and magnanimous Englishman, has founded a hospital of twenty-four beds near the Porte Maillot. It is almost always full, the number of English jockeys in Paris being sufficient to populate it with surgical cases. Drs. J. Cormack and A. Herbert are the attending physicians, who, with Mr. Wallace and the English consul, form the directors of this "Hertford British Hospital."

Medical Journalism in Canada.—Our old cotemporary the *Canada Medical Journal* has recently ceased to exist, and in its place two new journals have been started, —*The Canada Medical and Surgical Journal*, edited by Dr. Fenwick, the senior editor of the late *Canada Medical Journal*, and *The Canada Medical Record*, edited by F. W. Campbell. The editors have also assumed in addition to their editorial duties the responsibility of publishing their respective journals. There are at present three medical journals published in Montreal,—the two named above, and a French journal, *L'Union Médicale*. This useless and unnecessary division but weakens their influence, and will eventually make them a burden upon their projectors.

Ovariotomy.—The following words were uttered by Sir William Fergusson, at the late meeting of the British Medical Association, in Birmingham: "When ovariotomy was first propounded, it was little else than a theory,—a rash visionary scheme for notoriety; but, thanks to the well-directed efforts of Clay, Brown, Wells, Keith, and a host of others, the procedure is a well-established fact, which ranks among the best and safest efforts in surgery to save human life."

It would have been pleasing to Americans if Sir William had given merited credit to such names as McDowell, the first operator, Atlee, Peaslee, Emmet, T. G. Thomas, Storer, etc.

How Some Medical Schools are Chartered.—The original charter of the "Philadelphia University of Medicine" was hidden in a maze of measures entirely foreign to that subject, such as are too frequently heaped up in the Legislature to cover questionable objects. The original charter was contained in a section of an act passed in 1853, which authorized the authorities of the then borough of Frankford to borrow money to erect a gas-works; which also referred to a school-house at Powelton, to elections in a township in Juniata County, and various other matters.

Science and a Kind Heart.—A celebrated physician was called upon recently by a person suffering from rheumatism, who insisted upon his doing something for him. The physician wrote a prescription, and as the patient went out of the room, said to him, "I wish you would let me know if that does you any good, for I have myself been very much troubled with rheumatism lately."

The Largest Medical Library in the United States is that of the Surgeon-General's Office, Washington. It has 18,000 volumes. The second in size is that of the College of Physicians of Philadelphia, 15,000; and the third, that of the Pennsylvania Hospital, 13,000 volumes. [The library of the College of Physicians of Philadelphia now contains nearly 16,000 volumes. —Ed.]

Health of the Port of Philadelphia.—The *Medical and Surgical Reporter* says, "The Quarantine Master at the Lazaretto, who took down his flag for the season on Monday evening, September 30, reports the season from June 1 to October 1 as the healthiest for many years, as there has not been a single case of serious illness or contagious disease at the station or brought into port by any vessel."

The Road to Fame.—Even the fee of a patient who called him from his dissecting-instruments could not reconcile John Hunter to the interruption. "I must

go," he would say, reluctantly, to his friend, Lynn, when the living summoned him from his investigations among the dead, "and earn that d—d guinea, or I shall be sure to want it to-morrow."

BOSTON is to have a Board of Health; the administration of the sanitary affairs of that city under the arrangements hitherto existing having been so inefficient as to create great discontent among the people, as well as in the medical profession.

EXTREME EMACIATION.—Two hospital inmates were in conversation, when one of them said of a fellow-patient, "Murphy is very thin." "Yes," answered the other; "you are thin, and I am thin; but he is thinner than both of us put together."

CURIOUS.—A patent extension recumbent chair is advertised as useful "for *genealogical* purposes, without any appearance for that object."

Perhaps "gynæcological" would have better expressed the idea of the inventor.

ASSOCIATION OF MEDICAL SUPERINTENDENTS.—The 27th Annual Meeting of the Association of Medical Superintendents of American Institutions for the Insane will be held in Baltimore, on the fourth Monday of May, 1873.

WORCESTER CITY HOSPITAL, MASS.—By the will of the late Georges Jaques, of Worcester, Massachusetts, the sum of a quarter of a million of dollars was bequeathed to the city of Worcester, for the new Free City Hospital.

NEW MEDICAL SCHOOL.—The new College of Physicians and Surgeons at Wilmington, North Carolina, has been organized. Dr. J. Francis King is President, and Dr. William Walter Lane is Dean.

JAMAICA, W. I.—The new medical bill now before the Legislature opens the island of Jamaica to persons holding American diplomas in medicine and surgery.

THE College of Physicians and Surgeons of Syracuse University opened on the 3d instant, with a full corps of eighteen Professors.

THE corner-stone of the Buffalo Insane Asylum was laid September 18, with appropriate ceremonies.

MORTALITY OF PHILADELPHIA.—The interments reported at the Health Office for the week ending October 26, 1872, were 237; of which 125 were of adults, and 112 of minors. Among the causes assigned were:

Consumption of the Lungs	33
Other Diseases of the Respiratory Organs	33
Diseases of the Circulatory Apparatus	14
Diseases of the Brain and Nervous System	40
Zymotic Diseases (2 from Smallpox)	15
Typhoid Fever	6
Cholera Infantum	1
Dysentery	1
Casualties	4
Debility (including "Inanition" and "Marasmus")	26
Old Age	8
Still-born	15

OFFICIAL LIST

OF CHANGES OF STATIONS AND DUTIES OF OFFICERS OF THE MEDICAL DEPARTMENT U. S. ARMY, TO OCTOBER 21, 1872.

EDWARDS, L. A., SURGEON.—Assigned to duty at Madison Barracks, N.Y., as Post-Surgeon. S. O. 106, Department of the Lakes, Oct. 12, 1872.

WIRTZ, H. R., SURGEON.—Assigned to duty at San Francisco, Cal. S. O. 132, Department of California, Sept. 30, 1872.

ALEXANDER, R. H., SURGEON.—Relieved from duty in Department of the East, and to report in person to the Commanding General Department of the Columbia, for assignment. S. O. 240, War Department, A. G. O., Oct. 4, 1872.

GODDARD, CHARLES E., SURGEON.—Granted leave of absence for twenty days. S. O. 202, Department of the East, Oct. 19, 1872.

FORWOOD, W. H., ASSISTANT-SURGEON.—Relieved from duty in Department of the Lakes, and to report in person to the Commanding General, Department of Texas, for assignment. S. O. 240, c. s., War Department. By S. O. 106, Department of the Lakes, Oct. 12, 1872, relieved from duty at Fort Brady, Michigan, and ordered to comply with above order.

WATERS, W. E., ASSISTANT-SURGEON.—Assigned to duty in charge of Post Hospital, Fort Leavenworth, Kansas. S. O. 164, Department of the Missouri, Oct. 11, 1872.

HUNTINGTON, D. L., ASSISTANT-SURGEON.—Relieved from duty in Department of the East, and to report in person to the Commanding General, Department of the Columbia, for assignment. S. O. 248, War Department, A. G. O., Oct. 10, 1872.

DE GRAW, C. S., ASSISTANT-SURGEON.—Relieved from duty in Department of the Lakes, and to report in person to the Commanding General, Department of Texas, for assignment. S. O. 240, c. s., War Department.

GARDNER, W. H., ASSISTANT-SURGEON.—To accompany the companies of 6th Cavalry composing garrison of Fort Riley, Kansas, to that Post. S. O. 166, Department of the Missouri, Oct. 16, 1872.

COUES, ELLIOTT, ASSISTANT-SURGEON.—Assigned to duty as Post Surgeon at Fort Randall, D. T. S. O. 198, Department of Dakota, Oct. 19, 1872.

PHILLIPS, H. J., ASSISTANT-SURGEON.—To report to the attending Surgeon, Portland, Oregon, for medical attendance. S. O. 124, Department of the Columbia, Sept. 27, 1872.

LIPPINCOTT, H., ASSISTANT-SURGEON.—Granted leave of absence for six months, with permission to go beyond sea. S. O. 244, War Department, A. G. O., Oct. 7, 1872.

MONROE, F. LE. B., ASSISTANT-SURGEON.—To report in person to the Commanding General, Department of the South, for assignment. S. O. 240, c. s., War Department.

GIRARD, A. C., ASSISTANT-SURGEON.—Relieved from duty in Department of Texas, to proceed to New York City, and report by letter, on arrival there, to the Surgeon-General. S. O. 240, c. s., War Department.

YEOMANS, A. A., ASSISTANT-SURGEON.—Assigned to duty as Post Surgeon at Fort Sullivan, Maine. S. O. 194, Department of the East, Oct. 7, 1872.

MOFFATT, P., ASSISTANT-SURGEON.—Assigned to duty at Fort Leavenworth, Kansas. S. O. 162, Department of the Missouri, Oct. 5, 1872.

STYER, CHARLES, ASSISTANT-SURGEON.—Relieved from duty in the Department of the Missouri, to proceed to Philadelphia, Pa., and, on arrival, report by letter to the Surgeon-General. S. O. 240, c. s., War Department.

CORSON, J. K., ASSISTANT-SURGEON.—Relieved from duty in Department of the Platte, to proceed to Philadelphia, Pa., and, on arrival there, report by letter to the Surgeon-General. S. O. 240, c. s., War Department.

WEISEL, D., ASSISTANT SURGEON.—Relieved from duty in Department of Texas, to proceed to Baltimore, Md., and, on arrival, to report by letter to the Surgeon-General. S. O. 240, c. s., War Department.

COWDREY, S. G., ASSISTANT-SURGEON.—Leave of absence extended twenty days. S. O. 98, Military Division of the Missouri, Oct. 18, 1872.

REYNOLDS, FRANK, ASSISTANT-SURGEON.—Relieved from duty in the Department of the Columbia, to proceed to New York City, and, on arrival there, report by letter to the Surgeon-General. S. O. 238, War Department, A. G. O., Oct. 3, 1872.

SATURDAY, NOVEMBER 9, 1872.

ORIGINAL LECTURES.

CLINICAL LECTURE
ON CERTAIN PAINFUL AFFECTIONS OF THE FEET.

BY S. WEIR MITCHELL, M.D.,

Physician to the Orthopædic Hospital and Infirmary for Nervous Diseases.

IT is one of the advantages of the custom of lecturing clinically upon groups of cases, that it enables the teacher to bring these into relations for which the more precise method of an essay would be unsuitable. What I am about to say will so fully illustrate my meaning, that I need not pause here to explain myself much more at large. It is often a good and practical mode of teaching which, viewing a collection of cases united in appearance by some common and prominent feature, finally traces this to its various causes, and points out how diverse are the ways in which disease has been acting in the several instances presented.

Those who have followed my clinics with care must have noticed, now and then, cases which were chiefly conspicuous on account of pain in some part of the foot, or in both feet. This, at all events, was what brought them before us; and very often pain, and pain alone, was the marked and dominant symptom. Most happily the cases to which I am now referring are rare; but, besides being rare, they are also difficult to relieve, and yet more difficult to cure.

The patient who is now before us has brought the whole subject anew to my memory, and it may be worth while to use his case as a starting-point from which to study some of the less common forms of pedal pain.

This I shall the more willingly do, because one class at least of foot-pains has not been treated of in the books, and when it first came before me, was altogether a novel malady, so far at least as my experience or my book-knowledge was concerned.

You will now and then meet with persons whose feet are too flat, and who, when walking far, feel a certain amount of aching, and a sense of excessive local fatigue. Something can be done for such sufferers by the aid of proper shoes and equable support to the sole; but the natural difficulty is in itself altogether incurable.

The lad who is here to-day offers also an example of severe pain, which in him accompanies almost every effort at locomotion. He is a robust, well-formed person, in a condition of body which appears to be exceptionally good.

After a youthful life of entirely good health, he engaged in a business which kept him much on his feet and caused him also at times great fatigue. After some months, each occasion of extreme overwork resulted in paroxysms of pain, which were at first limited to the right sole, but soon extended to the left. Somewhat later it was also felt in the front of the right leg. For a long while rest relieved him, but there came a time when the attacks of pain grew more and more protracted, so that much greater periods of repose were needed to secure complete ease. When, after some years of torment, this man entered the hospital, we found that it was only in the morning that he was clear of pain, and that he had slight spasmodic shortening of the tibialis anticus, the peroneus longus, and the gastrocnemius muscles, which under ether relaxed completely.

After a good deal of doubt and some differences of sentiment in our consultations, Dr. Goodman divided the tendons of these three muscles in both legs, and put the feet at rest in properly constructed apparatus. Great relief followed, and it is said to have been permanent. After a time there was still some annoyance in walking, but it was very much less than before. The pain seems to have been due to the steady strain at the points of insertion of the muscles implicated, a strain of course increased by the varying positions which the feet assumed during exertion.

A few months since, a similar case occurred in the practice of Dr. Goodman, in the person of a young woman, J. M., aged twenty-two; single and in good general health, but rather anæmic in appearance. When sixteen years old, she began to have pain after exercise in the left leg and foot, and the pain was accompanied by violent contraction of the peroneus longus, gastrocnemius, and plantar muscles; at times also the toes became strongly flexed, and in every instance there was pain, not alone in the shortened muscle, but also in the foot, which as time went by became deformed so that she walked on the outside of the sole, and could not bring the heel down, while the foot itself was too much laterally arched. At the time she was seen at this hospital the muscles acted spasmodically in walking, and the pain, which was quite steady, was much increased by such exercise. The bellies of the muscles concerned were sore after exertion, and it was clear to us that not only were the slight deformities due to the spasm of the muscles, but also that the pain felt was in some way related to the spastic manner in which they acted when influenced by volition. Irritations, mechanical or electrical, addressed to the sole, caused no unusual movements, but I found that the muscles at fault were singularly easy to act upon when faradized. When I questioned her closely as to the pain, she insisted that it was steady, that all exercise terribly increased it, and that the worst torment was due to a crampy pain which affected the intrinsic muscles of the plantar region, and contracted the inner side of the foot. This came on daily three or four times a day, and lasted from fifteen to twenty minutes. I found in this, as in the lad's case, no known cause for the disorder, despite an investigation of every organ. She was not examined under anæsthetics.

Two years ago an apparatus was put on her foot, and an effort made to correct its deformities without section of the tendons. The attempt to stretch the shortened muscles gave extreme pain, and was soon abandoned. After consultation, Dr. Goodman and

I decided to divide the tendons of the gastrocnemius and peroneus longus, as well as the contracted plantar fascia. The operation gave immediate relief, and enabled us to straighten the foot and bring down the heel. The spasm of the muscles ceased after the section of the tendons, and although she has at times some annoyance from pain in these muscles, it is not great enough, as it was before, to inhibit exercise.

Last spring I saw a child aged eleven years, who had had, the autumn before, a prolonged ague. Late in the winter, being then to all appearance in robust health, she began to have, when walking, sudden and violent contractions of the right gastrocnemius muscle, which lifted the heel off the ground just at the usual time, that is, at the end of the step, and also held it thus drawn up for a moment. The pain was in the body of the muscle, and was severe. After a minute or two it left as the contraction ceased, to return again in half an hour or less. These spasms kept the muscle sore, and had begun to shorten it permanently. The muscle acted under a faradaic current, which failed to stir its healthier fellow in the left leg. As the child was here but for a day, I wrote an opinion advising section of the muscle. Soon after this, a long illness —a remittent fever, I believe, followed by pneumonia—kept the child nine weeks in bed, and either the long rest or some other agencies, the offspring of disease, entirely cured the spasms, which I learned lately have not returned.

There is to me something most interesting in the study of these curious cases of local spasm. They belong to a wide class called by the French *contractures*, the type of which is seen in those remarkable instances where cold or rheumatism seems to be the remote cause of muscular spasms, which may in time pass away, or may end, as in a case now in the children's ward, in deformity of every mobile portion of every limb. At present they concern us chiefly in their relation to the feet. So far as my own experience in this direction has gone (and it is a rather large one), only those muscular contractions are very painful or permanently so which are persistent enough or frequent enough to alter the shape of the foot and to keep it so deformed. Thus, in the lad whom you have just seen, the spasms were enduring and frequent, and finally caused distinct, although not excessive, deformity, accompanied by a permanent shortening of the disordered muscles. Now, the pain in the muscles existed chiefly when these were in action; but there was also another pain which was present then and remained when the muscle was at rest, and this was found to lie at or about the insertions of the muscles in the foot. In this boy's case there was at the muscular insertions a little puffiness, and at times slight tenderness. These latter symptoms do not always attend upon contractures elsewhere, or even constantly in those which affect the foot. Thus, in a remarkable example of "functional spasm," as I should like to call it,—that is, a spasm which is seen in a muscle when executing an ordinary action,—there was never any pain either in the muscle, although it was somewhat shortened, or at the point of insertion.

Neither in the case of J. W., aged twenty-nine, who was here in December last with a permanent contracture of the biceps, was there pain, save in the elbow and in the muscular mass. What now I most wish to point out is this: that there are rare cases of obscure pain in the feet which seem to be related to contractions of muscles, and that a close study of the case will often show a slight shortening of the muscles and more or less deformation of the foot. Cases of this kind must, I presume, be rare, because, although we see in this building a multitude of deformities of the feet, it is uncommon to find the part painful, no matter how great is the attendant contraction of muscles, no matter how widely the members have departed from the forms of health. Let me add, however, that nearly all of our deformed cases are children, or persons who acquired their disease in childhood, and that two of the three cases I have described were in adult life when their trouble began. In such persons the forms of parts offer greater resistance to change, are no longer plastic, and consequently suffer when subjected to such steady strains as tend to cause displacements. On some other occasion I hope more fully to discuss the various forms of contractures, but at present I have only so far dealt with them as to point out that in certain cases they seem to cause obscure forms of pain in the feet.

(To be continued.)

SIMPLICITY IN THE CLASSIFICATION OF TUMORS.

SYNOPSIS OF A LECTURE DELIVERED AT THE UNIVERSITY OF PENNSYLVANIA, OCT. 26, 1872,

BY DR. JAMES E. GARRETSON.

THE lecturer commenced his discourse with the suggestion that the histological distinctions of tumors were of little clinical import, and while of profound and most enticing interest to the student of histogeny, yet were of such little matter in practical surgery that he was oftentimes led to doubt whether one might not get along with much less confusion to the subject of diagnosis, without, than with, them. As the subject had presented itself to his experience and his judgment, he said, "'Tumors divided themselves, not into a multitude of classes, but simply into two; these two he would designate 'the explainable' and 'the non-explainable.' In the first of these classes was to be placed every tumor having in itself that which explained its presence, examples of which existed in the sebaceous tumors, the herniæ, ranulæ, etc.; in the second belonged, without distinction, saving the parasitic, all that remainder the explanation of which has to be sought outside of a local condition; examples in the latter directions being recognized in the nodes of syphilis, the degenerating glandular enlargements of tuberculosis, the multitudinous expressions of cancer."

All tumors of the first class, the lecturer suggested, were in themselves necessarily benign; all of the second class were to be viewed, not in themselves, but in the dyscrasia of which they were to be es-

teemed simply expressions. As an illustration in diagnosis, the following was offered: "A patient presents himself to a surgeon, having a tumor in his groin. What is the nature of this tumor? It might have the local signification of a hernia; of an undescended testicle; of a hydrocele of the spermatic cord; of an inflamed lymphatic gland. It might have the constitutional explanation of syphilitic or tuberculous bubo. It might be a cancer. To satisfy himself of the particular condition represented, the surgeon may only proceed as follows: First, he must recall the anatomy of the part. In the groin of the human male is a canal,—the inguinal canal. This canal is entered by a ring from the abdominal cavity, and has an outlet in a second existing in the aponeurosis of the external oblique muscle. In this canal lie, enveloped in a sheath, the spermatic vessels; this canal constitutes the passage transmitting the testicle from the abdomen to the scrotum. The entrance to this canal may permit the insinuation of a knuckle of omentum or intestine. In this inguinal region exist a number of lymphatic glands. This then is the anatomy, and these are the data. Is the tumor a hernia? There is no impulse on cough; no doughy feel; no diminution in size when the patient lies down; no ability to thrust the tumor into the abdomen; no enlargement of the inguinal rings. The tumor is not a hernia. Is it an undescended testicle? The testicle is to be felt in its place in the scrotum. The tumor is not a testicle. Is it a hydrocele of the spermatic cord? There is no fluctuation on percussion; no ability to change the position; no fluid as test is made with the exploring-needle or suction-syringe. It is not a hydrocele. Is it an inflamed gland of a local inflammatory signification? It has no such history. The tumor, then, is not of immediate signification; this it would seem we must know to a certainty. By exclusion, then, such a tumor is exhibited as belonging to the second class. The only question now is as to the vice represented. Syphilis and tuberculosis have a history. If such history does not exist, then a final exclusion pronounces the condition—whether rightly or wrongly need not just here be discussed—cancer. "May it," suggested the lecturer, "be implied that the tumor might be a fibroma or a sarcoma? We are not clinically to trouble ourselves about any such distinctions, for we are prepared to affirm that between such tumors distinction is seeming and not real; but it is urged that these do not kill, yet that carcinoma will. If such objection be abandoned, it may be admitted; but it has an explanation which is easily made evident. There is, we say, but one non-explaining vice; this vice puts on various phases. These phases are influenced by the malignancy of the poison, or by relation with the condition of the individual into whose system it has found ingress. This we may illustrate by an example. Four men go from a healthy to a malarious district; all live in the same house, and all are impregnated with the same poison. In a week one succumbs to a quotidian; in two weeks the second has a tertian; in three weeks the third dies from a congestive chill; while the fourth, preserved by an inherent resistive force, antagonizes the miasma entirely. Thus also in the cancer-vice: one man, either from the concentration of the virus, or from the absence of antagonizing power, dies quickly from a medullary expression; while another maintains a tumor for years in the condition of a simple sarcoma, succumbing finally in the battle, which, by the accident of some loss of resistive force, gives a mastery to the abeyant vice, the sarcoma being quickly degraded into that which the microscope has distinguished from it as carcinoma. The premise is to be maintained that any and every tumor which cannot be proved benign is to be deemed malignant. A self-explaining tumor expresses its own name; a non-self-explaining tumor demands from us no special regards for the distinctions of nomenclature, except as in an adjectival way these distinctions classify, for convenience in description, what are to be regarded as varying expressions of a common disease.

"Might it," said the lecturer, "just here be asked if no distinctions are to be made between the fibromata, the myomata, the myeloid of Paget, etc., because of its being the case that these have in themselves no more explanation of their appearance than have the carcinomata? Clinically it is to be affirmed that no surgeon lives who, upon the living subject, or upon the dead one either, has as yet been able to draw at any exact point a line of distinction between these growths and what histology denominates cancer; but I will not declare," said the lecturer, "that there is no such line. I hasten, however, to assert that if there is, it is my misfortune never as yet to have met with the practitioner who seemed able to map it off. Look, however, at the matter for yourselves.

"*First.* Fibrous Tumors — Fibromata. — The study of the fibromata begins with—1. Tumors which to the eye are composed of firm, interlaced fibrous tissue, and are, to the touch, hard, yet to an extent elastic. Such growths spring from the periosteal tissue, and find a favorite location in the maxillary antrum. When unmoulded, as when springing from a free surface, they are superficially lobed, and, as a rule, are ovoid in form; when occupying the sinus, they conform very much to the shape of the cavity, and are apt to retain their bony covering until they attain a size much greater than the site from which they originate. In color, these tumors are a faintly yellowish white, pure white, or a very pale red; in arrangement, the fibres are concentrically related, affording an expression of concentration, as if growing toward, rather than from, a centre.

"The diagnosis of this form of the fibromata lies in the isolation of the growth; in its elastic hardness; in the perfectly healthy and non-implicated appearance of the associate parts; in the absence of pain; and in the tardy growth. Such tumors are to be removed with an almost positive assurance of non-return.

"2. A second form of the fibromata is found in such close alliance with the first that no one might doubt the intimate relationship of the two, differing really alone from the first in the presence of a looser stroma, being what Rindfleisch, in his classification, would term 'a connective-tissue tumor'

This tumor, or rather this expression of a common tumor, has not the same concentric development, seeming, in this respect, to be less resisted by the neighboring parts; it does not infiltrate, but yet is of eccentric rather than concentric growth; or, if not this, then the fibrous relation is irregular. This is the first expression of the fibroplastic tumor of Lebert.

"3. The myomata of Virchow. Advancing one step farther in the appreciation of the fibromata, we meet with those spindle-shaped cells, which induced Virchow to give to the expression the name of myoma, and which, when possessed of more marked characteristics, constitute the fibro-sarcoma of Rokitansky. This is the fibro-recurring tumor, an expression of which Mr. Miller speaks—'as of a tumor ill defined, one which it may be doubted if it is not more properly classed when placed among the malignant conditions, seeing they are found prone to return, after excision, with singular obstinacy.'

"The eccentric fibrous tumor—fibro-plastic, fibro-recurring, myoma, fibro-sarcoma—presents alterations of structure, from which, at a point unknown to your lecturer, it passes into classification as sarcoma.

"*Second.* SARCOMATA.—The sarcomata are so called from presenting on section a fleshy look. A pure myoma would be alone the sarcoma, if by flesh-like was meant muscle-like; but by flesh-like has not been meant muscle-like; hence to say what is not a sarcoma, is with all writers merely an approximation. With such confusion our classification happily enables us to dispense. A sarcoma is what it is now designated by Billroth,—'a tumor consisting of tissue belonging to the developmental series of connective-tissue substances (connective tissue, cartilage, bone), muscles, and nerves, which, as a rule, does not go on to the formation of a perfect tissue, but to peculiar degenerations of the developmental forms;' in other words, it is an expression of the fibromata. Rindfleisch distinguishes the sarcomata into 'the round-celled sarcoma, the spindle-celled sarcoma, and the fibroma.'

"Another expression of this tumor is that classified and described by Mr. Paget as the myeloid,—so called from a resemblance to marrow,—an expression so lacking a persistent individuality that, even according to the classifier himself, such tumors vary from simple semi-fibrous, semi-marrow-like structure to those so heteroclitic that they seem to merge into the medullary."

Discussing the subject with large latitude, the lecturer resorted to the blackboard to demonstrate that the very highest expression of practice in the direction consisted in accepting and treating as cancer that which could not be shown not to be cancer. As an illustration, the epulides were used; four tumors of this class being shown to have in themselves explanation of their origin and local nature; while apart from these four, the lecturer insisted, no single one, whatever its histological quality, might have explanation given for its presence, and was, therefore, to be treated as the expression of a vice; that any and every one of the epulides, apart from the four described, was treated to the greatest good of the patient when it was viewed as cancer; and, this being admitted, that to know the four of self-explaining signification, was necessarily clinically to know all the rest; at any rate, was to know what best to do for them, which, after all, was the matter which most concerned the usefulness of a surgeon to his patient.

In giving this synopsis, we would not be understood as having repeated the lecture with any fulness. The subject was discussed in proportion to its length and depth, and if histology was denied importance of position, histological aspects, particularly those pertaining to the histoid mixed tumors, were elaborated with all care,—being employed, however, to show what seemed to the lecturer the weakness, rather than the strength, from the clinical aspect, of any classification so founded.

NOTES OF HOSPITAL PRACTICE.

JEFFERSON MEDICAL COLLEGE.

SURGICAL CLINIC OF PROFESSOR S. D. GROSS, M.D.

Reported by FRANK WOODBURY.

LATERAL OPERATION FOR LITHOTOMY.

THIS man, thirty-eight years of age, has suffered for years with an aggravated irritation of the bladder. He is troubled with frequent desire to pass his urine, which is small in quantity, and when flowing stops suddenly, with a painful sensation extending through the bladder and adjacent parts. His appetite is poor; he has some dyspeptic symptoms, and his bowels are constipated; he is losing flesh, and his health generally is below par.

These symptoms might be produced by a vesical calculus. The characteristic sign is that sudden check to the flow of the urine, which he complains of, which might be produced by a foreign body, such as a stone, which, being movable, would naturally be washed by the water to the neck of the bladder, and there act as a valve obstructing the current. We have a means, however, of determining this positively, and of feeling and hearing a stone, if one exists, by means of an instrument termed a sound. This I have used in the present case, and have found that there is a large stone in the patient's bladder. We should make it a rule, in proceeding to cut a patient for stone, to pass the sound and find the stone at the time of operating. Although all the rational signs are present, unless we can obtain this evidence before operating we should defer the case until another occasion, no matter how positive we are that we have felt and heard it on previous examinations. By neglecting this precaution many patients have been subjected to the pain and perils of lithotomy, in whom after the operation no stone could be found. Many cases of this kind are on record. The greatest care should be exercised in sounding the patient, and this should be repeated on successive occasions, until absolute certainty is attained as to whether a stone exists or not. Cases occasionally happen where all the symptoms are present, but no calculus can be discovered; or a stone may really exist, yet the surgeon be unable to detect it by any means at his command. This might occur in a case of sacculated bladder, where the concretion is encysted in a fold in the mucous lining,

or it might be hidden in the cul-de-sac at the bas-fond of the bladder, behind the prostate gland.

Sounding enables us to ascertain positively the existence of a stone, and gives us an idea of its size, situation, and character; whether smooth or rough, solitary or multiple. The instrument used is generally made of polished steel, and comes in sets of varying curves and different sizes, of about twelve inches in length. The instrument is warmed and oiled, and introduced as an ordinary catheter, allowing it to glide along the urethra by its own weight. The patient's rectum should be empty and his bladder about half full of urine at the time of the examination, which should be conducted with the patient supine in bed, with his thighs and knees flexed and well separated. The sound will frequently encounter the stone immediately on entering the bladder; otherwise, it must be moved around in various directions. When the stone is suspected of hiding behind an enlarged prostate, the forefinger may be introduced into the rectum, so as to push up this portion of the bladder. If the examination is attended with much pain, or the patient is a child, an anæsthetic may be given. Many years ago a French surgeon invented a little circular sounding-board, which is attached to the handle of the sound, whereby the peculiar "click," made by the instrument striking the stone, is made more evident and distinct. The patient's system should be in a manner prepared before the sound is introduced. In case he comes from a distance, he must perfectly recover from the fatigue of the journey. From a neglect of this, much suffering has been produced. Paget records six cases where death ensued from a mere sounding for stone; the procedure, therefore, is not without risk to the patient.

Vesical calculus is rare in the female, probably because the shorter and more capacious urethra allows prompt excretion to many deposits that under other circumstances would form concretions. From the statistics of the affection, it is also seen that negroes are not so liable to this disease as the white race. Drinks of certain kinds, such as cider, have been known to produce this disorder, which is also very prevalent in limestone regions, although not exclusively confined to them. Food also exercises an influence over calculous deposits, and the poor are more frequently attacked than the rich. Gout and rheumatism frequently are accompanied by the formation of the variety known as the uric acid calculus. The growth of a stone is generally slow, and extends frequently over a series of years. It has its origin most frequently in the kidney, from whence the ureter conveys it to the bladder; or a foreign substance, introduced through the urethra, may be the nucleus of the concretion; or it may even originate in the bladder itself, by deposit from urine which is unusually rich in the earthy constituents.

These calculi are of different chemical composition. The most common variety is composed of uric acid; the next in frequency is the oxalic calculus, which consists principally of oxalate of lime; then follow the triple phosphate, the ammoniaco-magnesian, the cystic, fusible, and xanthic; the latter being extremely rare. The oxalic variety is hard and tuberculated, and hence is sometimes called the mulberry calculus; it is always single, except when very small and smooth, when it is generally multiple, and receives the name of the hemp-seed calculus.

This body in the bladder keeps up a constant irritation and inflammation of the mucous lining, producing all the symptoms of cystitis. Hypertrophy of the walls of the organ with diminution of its capacity may result, or the calculus may ulcerate through, producing extravasation of urine and threatening life. Or the stone may remain and gradually increase in size, causing organic disorder of the urinary organs, producing much suffering to the patient, and finally death will ensue from hectic irritation.

When the stone is very small, it may be extracted through the urethra; or, if of medium size, it may be crushed by the operation of lithotrity, and the fragments removed through the same channel; but when of large size the safest and best means of removing it is by the operation of lithotomy. This is performed either by the lateral, bilateral, or median incision. The lateral operation is the one I prefer, and generally perform. The patient requires a certain amount of preparatory treatment before being subjected to the risk of an operation. Rest and a light diet for a few days are essential. Castor oil is administered the evening before operating, so as to empty the bowel, or it may be cleansed out by an enema. The rectum must be thoroughly evacuated, because, otherwise, it would be in the way, and might be accidentally cut, producing a recto-vesical fistula, at once the most intractable and one of the most disgusting affections that ever made a patient miserable for life. It would be better to let him die under the operation than by such an affliction to render him perpetually obnoxious both to himself and those around him.

Never commence the operation with the patient on a bed, as it is entirely too low. He must be placed on his back, upon a table, with his buttocks brought to its edge, as soon as the anæsthetic has produced its effect. The patient's bladder must be partially full of urine at the time, in order to facilitate finding the stone, which will probably be brought down with the gush of urine as soon as the orifice is made. A staff is then passed into the bladder, having its handle inclined towards the right groin of the patient, and held by an assistant, who also holds the scrotum out of the way; two other assistants hold the limbs widely apart, with the thighs and knees firmly flexed. The operator then takes his position in front of the patient. I prefer to kneel on one knee, as being the most convenient. The left forefinger is inserted into the rectum to hold it up and induce its contraction, and render the integument of the perineum tense. The left side is generally chosen as most convenient for the right hand of the operator. The knife is then introduced a little to the left of the raphé, about an inch and a quarter in front of the anus, and the incision carried obliquely backwards, about three inches, to a point half way between the tuberosity of the ischium and the anus. The tissues are torn and picked away until the urethra is found at the bottom of the wound. The knife is then thrust into the membranous urethra and run along the groove of the staff into the bladder, in its passage partially dividing the neck of the organ and the left lobe of the prostate gland. The urine then gushes out, and the stone is readily found and extracted with the scoop or lithotomy-forceps. If the stone is very large, it may be crushed and removed piecemeal, in preference to enlarging the opening. The bladder is then immediately washed out with a syringe and tepid water, to remove all the fragments that might otherwise form nuclei for fresh growths. Any bleeding vessels are tied after the operation. The wound will afterwards fill up with granulations, and the urine resume its natural channel.

[This operation was performed as described. The stone was quite large, and so soft as to break in several pieces when grasped by the forceps. The wound was plugged with styptic cotton, and the patient conveyed to his bed, which had over the lower half of the mattress a large piece of oil-cloth placed, covered, for the purpose of absorbing the urine, by a folded sheet, called the draw-sheet, which was frequently changed. A full dose of morphia was given immediately after the operation. The patient recovered sufficiently to leave the hospital at the end of the eighth week, and returned

home to the country perfectly relieved of the symptoms that had given him trouble for so many years.]

SYPHILITIC DACTYLITIS.

This is an affection that by some is thought to be extremely rare, but which is often seen at this clinic, and is referred to in my "Surgery" as being sufficiently frequent. It is known as syphilitic panaris or dactylitis syphilitica. It attacks one or more of the fingers, and consists of a deposit of the gummous matter peculiar to syphilis, both under the periosteum and in the structure of the bone itself, which becomes softened and expanded to many times its natural size. It occurs generally in children before the seventh year, in whom it is produced by inherited syphilis.

This little colored boy, two years and six months old, was unfortunate enough to have his hand trodden upon, a year ago, which resulted in this disease of the metacarpal bone of the thumb. But this result could not have ensued if this taint were not in his system. His mother states that she has had four children, who are all dead except this one, and she has miscarried several times. His father also is not healthy. The child's system needs invigorating. He shall have a salt bath every day, and his diet shall be carefully regulated, so as to consist only of the most nourishing food. A piece, the size of a walnut, of unguentum hydrargyri, may be rubbed on the inside of his thighs every second day. An emollient poultice may be applied to the affected finger.

[This case, and the one preceding, appeared at one of the clinics of the auxiliary course, during the summer.]

NECROSIS OF THE TIBIA.

This boy, ten years of age, has had a disease of his right tibia for six years. We notice a deformity in the limb; the bone is enlarged throughout its entire extent, and bent forward in the shape of a bow; this was caused by the constant pressure of the body in walking upon it, when the bone was softened by disease. There are two sinuses, from one of which a large portion of dead bone protrudes. The discharge is thin, ichorous, and sometimes sanguinolent, bearing no resemblance to healthy pus. We find the fibula perfectly natural and unaffected.

The first indication is to remove the dead bone, which we can readily do here by enlarging the opening slightly, and extracting this large sequester with the forceps. We next carefully scrape the walls of the cavity, removing all the disintegrated carious structure, unhealthy granulations, and cacoplastic lymph, which would interfere with healthy repair. Then wash it out with the syringe and cold water. Granulations will spring up, bone will be deposited, and the wound heal; but there will be no reproduction of the medullary canal, and the bone will never regain its natural weight, being always a little heavier. This bend in the bone it is too late to remedy. After the operation the limb shall be wrapped in a weak solution of acetate of lead. We will not prescribe for him, as he is under the care of a physician who brought him to the clinic.

This disease is strumous in character; in other words, it is a late outgrowth of syphilis. In its early stages the pain is generally acute, depriving the patient of sleep and appetite, and producing severe constitutional effects. Where this predisposition exists, the affection comes on from the slightest causes, such as a blow on the part, or suppression of the cutaneous perspiration, or may even occur without any assignable cause. The disease is cowardly, and attacks the least defensible spot in the patient. We may assume that this tibia was the weakest part of this boy's frame, being weak by inheritance. Whether it commenced in the bone or periosteum first, it is impossible to say, because they are both implicated in the subsequent morbid action.

A NEW RULE FOR DOSES.—Dr. E. H. Clarke (*Boston Medical and Surgical Journal*, September 26, 1872).—The doses, given in works on materia medica for the administration of medicines, are intended for adults of average health and strength. These average doses are of course varied by the physician, when prescribing, so as to suit differences of age, disease, sex, temperament, idiosyncrasy, and the like. Of the various modifying circumstances that affect the dose, age has always been recognized as the most important, as it is the most obvious one. Several schemes or rules, intended to aid the memory in apportioning doses to different ages, have been proposed. Two are commonly referred to as the best. Both of them are familiar, and both may be found in the United States Dispensatory.

The first is the table of Gaubius, according to which the dose of an adult being one, or one drachm, that of a person from

14 to 21 years will be $\frac{2}{3}$ or 2 scruples.
7 to 14 " " " $\frac{1}{2}$ drachm.
4 to 7 " " " $\frac{1}{3}$ or 1 scruple.
At 4 years old, the dose will be $\frac{1}{4}$ or 15 grains.
At 3 " " " " " " $\frac{1}{6}$ or 10 grains.
At 2 " " " " " " $\frac{1}{8}$ or 8 grains.
At 1 " " " " " " $\frac{1}{12}$ or 5 grains.

Dr. Young's rule, extracted from the Pharmacologia of Dr. Paris, is generally preferred, on account of its simplicity, to the table of Gaubius. It is this: "For children under twelve years, the dose of most medicines must be diminished in the proportion of the age to the age increased by twelve; thus, at two years to $\frac{1}{7}$: viz., $\frac{2}{2+12} = \frac{1}{7}$. At twenty-one the full dose may be given."

Physiological experiment has shown that the weight of animals is not only as important an element in apportioning doses of drugs as age, but is probably a more important one than that. Thus, Dr. Fraser, of Edinburgh, in his recent admirable monograph on physostigmia and atropia, has shown that the minimum lethal dose of sulphate of physostigmia for rabbits is 0.04 grain for every pound. M. Claude Bernard has called attention to the fact that in physiological experiments with drugs on animals, the dose should vary with the weight of the animal. Clinical observation shows that men in this respect are not unlike other animals; and that in the administration of remedies, the dose should vary with the weight of the patient in order to obtain the best therapeutical result. Guided by this principle, it is easy to give a rule for doses that is more exact and more easily remembered than the table of Gaubius or the equation of Dr. Young.

Assuming the average weight of an adult to be one hundred and fifty pounds, for whom an appropriate dose is one or one drachm, the dose of most medicines must be increased or diminished in the proportion of the weight of the patient to that number of pounds. This proportion is represented by a fraction, whose numerator is the patient's weight and whose denominator is 150. If a child at birth weighs six pounds, the appropriate dose for it would be $\frac{6}{150}$, or $\frac{1}{25}$; if it weighs ten pounds, $\frac{10}{150}$, or $\frac{1}{15}$. A child two years old, weighing twenty pounds, would require $\frac{20}{150}$, or about $\frac{1}{7}$ of an adult dose; or, more precisely, $\frac{1}{7\frac{1}{2}}$, which is exactly halfway between the quantity indicated by the table of Gaubius for a child two years old and that indicated by Dr. Young's scheme for the same age. A person whose weight is two hundred pounds should have $\frac{200}{150}$, or $1\frac{1}{3}$ of an average adult dose. A child twelve years old, weighing 75 pounds, would require $\frac{75}{150}$, or $\frac{1}{2}$ of an average dose.

The modifications of the average dose, demanded by a patient's idiosyncrasy, disease, and other conditions than age or weight, are not, of course, met by the above rule.

PHILADELPHIA
MEDICAL TIMES.
A WEEKLY JOURNAL OF
MEDICAL AND SURGICAL SCIENCE.

The Philadelphia Medical Times is an independent journal, devoted to no ends or interests whatever but those common to all who cultivate the science of medicine. Its columns are open to all those who wish to express their views on any subject coming within its legitimate sphere.

We invite contributions, reports of cases, notes and queries, medical news, and whatever may tend to increase the value of our pages.

All communications must bear the name of the sender (whether the name is to be published or not), and should be addressed to Editor Philadelphia Medical Times, care of the Publishers.

PUBLISHED EVERY SATURDAY BY
J. B. LIPPINCOTT & CO.,
715 and 717 Market St., Philadelphia, and 25 Bond St., New York.

SATURDAY, NOVEMBER 9, 1872.

EDITORIAL.

PHYSICIANS' FEES.

THE medical profession stands to the public in a double relation; on the one hand, as business men, we have a commodity to dispose of,—our medical skill; on the other, as humanitarians, we have an ability to relieve some of the inevitable woes of our race. Very few men, rich or poor, go through life without at some time urgently needing the advice of the physician; and this need is one universally recognized as imperative. A man may have to forego his rights because he cannot afford to employ a lawyer; no man must languish or perish with disease because his purse is light. We believe it will not be disputed, that the gratuitous services rendered by physicians at the demand of the public are far greater than those asked of any other set of men. And this has had the effect of developing our humanitarian relation to the community at the expense of our business interests.

We hold that our services have a market value, variable, but still actual. It is the difficulty of determining this value, the impossibility, indeed, that makes fee-bills and scales of charges so unsatisfactory. Shall the visits of yesterday's graduate be paid for at the same rate as those of the man who has given half his life to the study of disease? Is a visit a visit, no matter whether the case be one of trifling indigestion or of the gravest typhoid? Shall "the passing of a catheter" be worth just so much, no matter whether the operation is so easy that a child might do it, or so difficult as to demand the utmost dexterity for its success?

We have said enough to show how unsatisfactory and even how useless must be any action taken by the College of Physicians of Philadelphia in regard to the proposed changes in the fee-bill for this city. Every one knows that this matter is in agitation; and almost every one knows that a suggestion to abolish the fee-bill entirely, made a year or two since, was negatived. A sliding scale we are told we cannot have. Hence the only plan is for the College to again establish a sort of average tariff of charges.

Whether physicians shall adhere to this scale or not, in making their charges, each must determine for himself. We believe it would be far better for the older men, and those of special reputation and large business, to raise their fees,—to make more money by less arduous work. And in doing this, we do not think they would sacrifice one iota of the honor or delicacy of our profession. The highest possible authority has said, "the laborer is worthy of his hire."

THE WELLS NATIONAL TESTIMONIAL FUND.

AS many of our readers are aware, a fund is being collected for the benefit of the family of Dr. Horace Wells, who deserved at least a share in the credit of the discovery of the artificial production of anæsthesia. There has always been some doubt whether he was not really the experimenter who first laid the foundation for this vast benefit to suffering humanity; and this doubt ought to be enough to secure for his family, now in very narrow circumstances, the liberal aid of all who have seen or felt the value of the boon which he helped to confer. We trust the appeal will meet with a hearty response from his countrymen.

Contributions may be sent to the Treasurers of the Fund: W. R. Vermilye (Vermilye & Co., Bankers, Nassau Street, N.Y.); Samuel S. White, D.D.S., Twelfth and Chestnut Streets, Philadelphia; or by the special collector for Philadelphia, S. B. Merkle, M.D., care of Major S. T. Pratt, 7 and 8 Ledger Building. Checks or money-orders are preferable for all sums over five dollars.

WILLS HOSPITAL LECTURES.

A VERY valuable course of instruction in ophthalmology, combining the didactic with the clinical, is projected at the above institution for the months of November, December, and January. Dr. Levis takes charge of the Operative and Clinical Sur-

gery of the Eye; Dr. Harlan, of the Anatomy of the Eye, Accommodation, and Ophthalmoscopy; Dr. Dyer, of the Physiology of Vision, Refraction, and General Diseases of the Eye.

It would be difficult to overestimate the advantage of such a series of lectures and demonstrations to the student, the recent graduate, or the country practitioner.

CORRESPONDENCE.

COOL.

To the Editor of the Philadelphia Medical Times:

DEAR SIR,—My friend Simkins has a large practice,—forty patients daily,—so he says. In the summer, when the mercury shows a tendency to reach 100° in the shade and hold fast to it, Simkins, my friend, feels that his health demands a sojourn at the sea-shore, where, curiously enough, most of his patients take quarters. Before taking his departure, however, he drops me a hasty note, as follows:

"My dear Timkins,—Off to the shore to-day; have left my patients in your charge. Keep cool. Good-by.

"Yours,

"Simkins."

I, Timkins, being an humble practitioner, with one patient daily, feel the immense responsibility of having Simkins's patients under my charge, and, perspiring day and night in performing his duty, destroy shoe-leather, and expend car-fare, narrowly escape an attack of heat-fever, toil and boil for my friend Simkins's patients.

The season ends; the mercury falls, and I receive another note from my friend Simkins:

"My dear Timkins,—Home again. Please send me, at your earliest convenience, a list of the visits made. Hope you have kept cool. Thanks for the work you have done for me.

"Yours,

"Simkins."

I am cool now, Mr. Editor; cool to my friend Simkins.

Yours, obediently,

Timkins.

PROCEEDINGS OF SOCIETIES.

PATHOLOGICAL SOCIETY OF PHILADELPHIA.

Thursday Evening, September 12, 1872.

The President, Dr. J. H. Hutchinson, in the chair.

DR. O. H. ALLIS presented a specimen of *aneurism of the ascending aorta*. The specimen was referred for description to a committee consisting of Drs. Harrison Allen and W. W. Keen, who reported as follows:

"The committee appointed to examine the specimen of aortic aneurism presented by Dr. Allis, Sept. 26, beg leave to report:

"That the aneurism involved the ascending portion of the arch alone, *exclusive* of the bulb. None of the cardiac valves were diseased. The aorta was exceedingly atheromatous beyond the aneurism. The walls of the sac consisted of the dilated aorta and the condensed surrounding tissue. Its relations to the pericardium, as the specimen exists, we were unable to determine. The pulmonary artery was not compressed. The contents of the sac consisted of a very large mass of laminated fibrin, and on the internal surface a considerable amount of clotted blood.

"The effects on the sternum, the ribs of the right side, and intercostal spaces, were as follows:

"The sternum was eroded at the right border in the third intercostal space.

"The third rib was pushed up and eroded in its under surface at one point.

"The fourth rib was pushed forward, greatly eroded on its upper surface, so as almost to be fractured at one joint. On its under surface were a number of osteophytes.

"The fifth rib was eroded on its upper surface, but not pushed down.

"The third and fourth intercostal spaces were greatly widened: the third by the erosion and lifting of the third rib, narrowing the second space; the fourth by the simple erosion of the fifth rib, the fifth intercostal space being normal."

Dr. H. C. Wood exhibited a section of a portion of the femur from *a case of rheumatoid arthritis*, in which the *medullary cavity was wholly occupied by cancellated tissue*. The patient was a woman aged twenty-three years, who died of shock after the operation of opening an abscess.

Dr. W. Pepper regretted that a larger portion of the bone had not been examined, so as to ascertain if some traces of a medullary cavity did not exist higher up. As to the precise nature of the process by which the place of this cavity was still occupied by the cancellous tissue, it appeared to him unlikely that it had been purely one of the formation of new cancellous tissue. According to his own observations upon the production of cancellous tissue in cases of hyperostosis, there will usually be found traces of new-formed layers of compact bone, which has undergone a more or less marked consecutive conversion into cancellous tissue. In the present specimen, on the other hand, the tissue occupying the centre of the shaft was apparently identical and directly continuous with the normal cancellous tissue nearer the periphery.

Dr. James Tyson presented a specimen of *cirrhotic or "hobnail" liver, unusually small*, removed from M. T., intemperate, aged fifty-six, who was admitted to his ward in the Philadelphia Hospital August 8, 1872, and died September 18. On admission he was the subject of anasarca of the lower extremities, marked ascites, and hydrothorax. There was a faint mitral murmur. The urine was scanty, but contained no albumen.

Tincture of chloride of iron was freely administered, and one-eighth of a grain of elaterium given every other day, which produced large watery evacuations from the bowels, but was discontinued on account of the prostration resulting. Two weeks before death, paracentesis abdominis was performed, and two hundred and forty ounces of fluid drawn off. Later, obstinate nausea and vomiting supervened, and he died with symptoms of dyspnœa.

The post-mortem examination revealed large quantities of fluid in the pleura, pericardium, and peritoneal sac. The liver was a beautiful example of a "hobnail" organ, less than half the normal size and weight. The spleen was pultaceous and considerably enlarged. The other organs were healthy.

Dr. WILLIAM PEPPER exhibited a specimen of *thread-like worm* said to have been passed by a Texan boy. The worm was referred to the Committee on Morbid Growths, who reported it to be a specimen of a male *Gordius aquaticus*, or horse-hair worm, of chestnut-brown color, a foot in length, a little more than half a line in breadth, with bifid caudal extremity.

Dr. J. EWING MEARS presented a specimen of *villous cancer of the vagina*, removed from a patient forty-two years of age.

The attention of the patient was first directed to the growth by the occurrence of a severe hemorrhage, in June last. This has recurred at varying intervals, and has produced much prostration from the loss of blood.

On making a vaginal examination, the growth was found occupying the posterior wall, about the junction of the upper with the middle third. It consisted of a villous or dendritic mass about the size of a small orange, and was excessively vascular. It appeared to surround an opening or depression into which the finger could be introduced. Rectal examination failed to discover that there was any communication established between it and the vagina. The growth was removed by the scissors, and the part cauterized.

Dr. MEARS thought it belonged to the third form of villous cancer described by Rokitansky, in which "the flask grows with considerable dilatation into a stem, which gives off branches which do not ramify further, but break up into a great number of flask-shaped sprouts."

Dr. JOHN S. PARRY remarked that *villous cancer* in this situation was very rare in his experience; that it usually affects the os uteri; and, indeed, that primary cancer of the vagina is rare in any form.

Dr. MEARS said that he had suspected there was disease of the rectum in this instance, and that he had therefore examined it, but was unable to detect any.

Dr. H. LENOX HODGE remarked that his own experience coincided with that of Dr. Parry. He remembered to have seen only two cases of cancer of the vagina, one of villous cancer beginning with the os uteri, and a second of epithelial cancer, much lower down, and involving the lower part of the rectum, with ulceration so that the two passages freely communicated.

The specimen was referred to the Committee on Morbid Growths, who reported:

"The tumor from the vagina, presented by Dr. Mears, is a carcinomatous papilloma, or 'Zottenkrebs' of the Germans. The papillæ of the dendritic growth have each a frame-work of connective tissue terminating in a nodular-like expansion, with similar processes from the sides. In it are found broad and very thin-walled blood-vessels. The papillæ are covered by several layers of simple cylindrical epithelium." A section of the tumor prepared by the committee was placed under the microscope, from which a very clear idea of the structure of the growth was obtained.

Dr. J. EWING MEARS presented a specimen of *scirrhus of the mammary gland*, removed by him from a patient aged thirty-seven years.

The tumor was first observed eight months since, when it existed as a freely movable firm mass, about the size of a hen's egg, occupying the superior portion of the left mamma. At that time the health of the patient was good, although she suffered from the characteristic pain accompanying these growths. Extirpation of the tumor was advised, but the consent of the patient could not be obtained. She was then placed upon arsenic, with the view to arrest the further development of the tumor. Notwithstanding its persistent use, the tumor increased greatly in size, the health of the patient declined, and the symptoms became quite aggravated in character. A gland of the axilla was slightly enlarged; it did not appear to be cancerous, and was therefore not removed.

The tumor, with the entire gland, was removed in the usual manner.

Dr. MEARS also presented the *heart, kidneys, portion of liver and intestines*, from a case of general fatty infiltration and degeneration. There were the symptoms of Bright's disease before death, and the kidneys were highly fatty, but not more so than the other organs.

REVIEWS AND BOOK NOTICES.

HAND-BOOK OF COMPOUND MEDICINES; OR, THE PRESCRIBER'S AND DISPENSER'S VADE-MECUM. By ARNOLD J. COOLEY, Author of "Cyclopædia of Receipts," etc. Small 8vo, pp. 219. Philadelphia. J. B. Lippincott & Co.

This little volume is divided into two portions; the first being devoted to "pills, boluses, globules, grains, and granules," and the second to "mixtures." In each the preparation, formulæ, doses, leading uses, and synonyms of the various articles are given, and, as it seems to us, with great conciseness and accuracy. Although prepared in a London pharmaceutical atmosphere, and intended for English use, such a book cannot but be valuable to physicians everywhere, presenting many and varied combinations, and in this respect embodying the results of experience gained in the public and private practice of the British metropolis.

NORMAL OVARIOTOMY. By ROBERT BATTEY, M.D. From the *Atlanta Medical and Surgical Journal*, Sept. 1872.

This pamphlet consists mainly of a detailed account of a case in which the author performed, upon a young lady aged twenty-three years, the removal of both ovaries, *which were normal in condition*, with a view, says he, "to establish at once the 'change of life.'"

It calls to our mind a story of a somewhat distinguished French surgeon (Delpech, if we mistake not), who removed both testicles for purely functional disease, and was assassinated in his carriage by his patient a few years later.

GLEANINGS FROM OUR EXCHANGES.

BRITTLENESS OF THE BONES IN THE INSANE.—We find the following in the notice of "Asylum Reports" in the *Journal of Mental Science* for July, 1872:

"We notice several cases of broken ribs, and the observations made seem to corroborate the opinion that the condition of the bones is peculiar, at all events, in some classes of the insane. We are disposed to think that it is chiefly among general paralytics that these fractures occur, as illustrated by the cases appended.

"At Hanwell, a man, æt. 55, 'affected with mania and general paralysis, died of pleurisy, the result of fractured ribs.' Another man, æt. 45, affected with the same disease, had a fracture of the right ramus of the lower jaw, two fractured ribs, and laceration of the right kidney; 'how caused there is no evidence to show.'

"At the Hants Asylum, a male patient, a general paralytic, fell against a table and fractured a rib. This was the only case in which death followed, and an inquest was held, the jury giving a verdict of 'death from general paralysis, accelerated by a fractured rib.'

In this case I requested the coroner to call in a medical man unconnected with the Asylum to make the post-mortem examination, which he did, and the evidence he gave showed that the bone was very brittle and the character of its structure changed, so that it fractured very easily. This was afterwards confirmed by an able microscopist, who examined a fragment of the bone under the microscope.

"At Wilts a female idiot, æt. 53, 'seemed to have turned over on her arm in her sleep,' and fractured her humerus in the act. She had suffered from rheumatic gout, and 'it is probable that the bones are atrophied, and consequently abnormally fragile.'

"At Worcester Dr. Sherlock narrates two cases of broken ribs, on which inquests were held as follows: Both patients, men, were suffering from advanced general paralysis, and when these injuries were discovered, were, and had been for some time previously, in a prostrate, hopeless, and very exhausted state. In both cases the bones were found to be in a very diseased and brittle condition, and would have given way under a degree of force perfectly inadequate to produce such a result in a healthy subject. A rib removed from its connections was easily cracked across by the force used by the finger and thumb of the operator's hand. In one of these instances the fractures were ascertained probably on the morning of the day of their occurrence, and in the other case it appeared from the examination after death, that the ribs found broken were of very old standing, had consolidated and become solidified, and were in that state when the man was sent here for care, but that in the course of the exhausting disease from which he suffered, and which was accompanied with extreme emaciation and other signs of disintegration and degeneration, several of the united fractures had again broken loose and manifested themselves upon the examination of the surgical explorer. We know that this result happens in the case of other bodily diseased conditions, and in some earlier reports your attention was called to a similar case, where it was conclusively proved that a man had sustained similar injuries long before he was sent to your Asylum; and, as in the present case, some of the fractures became disunited, and obviously only a short time before his decease. In neither case this year was any inflammatory condition excited in the lungs or pleuræ, and the jury found that death had resulted from the organic disease from which they were suffering.

"At the York Asylum, 'an old, feeble man slipped down in the gallery, and fractured his leg just above the knee; having previously sustained a fracture of the thigh in the same manner. It was purely accidental, and was evidently dependent upon an unusually brittle condition of the bones. The patient progressed favorably for some time, and then sank from exhaustion and shock."

Extreme Atrophy of the Ribs in an Insane Woman. By Prof. Ludwig Meyer, of Göttingen (*Virchow's Archiv*, 1871; quoted in *Schmidt's Jahrb.*, Bd. 154, 1872, No. 4).—This woman, æt. 55, died of suppurative nephritis, in the Göttingen Lunatic Asylum. The ribs appeared excessively reduced in breadth as well as in thickness, being in some places almost like a knife-blade. A slight attempt to bend them caused them to give way. They broke like brittle pasteboard, short off, without splitting. The bone was neither soft nor elastic, but crepitated under the finger; but it sprang back to its place as soon as the fracturing force was removed. The ribs were very light in weight, their surface furrowed and vascular; the cortical substance a mere paper-like, translucent shell; the spongy substance much thinned, and its cells filled with a thin, greasy, brownish-red liquid. The cortical substance, when treated with muriatic acid and examined microscopically, seemed normal; the bone-corpuscles of the usual appearance and number; the Haversian canals wide, pouched out, and showing a membrane striped, thick, studded with fatty granules and granular masses. The liquid contained blood-corpuscles and fat-granules. The other bones were normal or almost so. Professor Meyer thinks this lesion due to the especially diminished respiration often observed in the insane. No fracture had occurred during life.

Primary Cancer of the Trachea and Bronchia. (Dr. Langhaus, of Marburg, *Virchow's Archiv*, vol. liii. part 4, 1871).—The following case shows that the bronchia and trachea may be the seat of primary cancer. A man forty years old had suffered for a year from symptoms indicative of stenosis of the bronchia, especially of the right bronchus. It was impossible to discover the cause of this stenosis. Finally the patient, after frequent attacks of suffocation, died in one of them.

The post-mortem examination revealed nothing abnormal in the abdominal cavity. In the thoracic cavity nothing abnormal was discovered, save the stenosis of the air-passages. The lungs were normal and inflated, the bronchial glands greatly swollen and very melanotic, without cancerous deposits. The air-passages presented nothing abnormal to external observation; but upon opening them extensive disease of their walls was found at the bifurcation of the trachea. At this point the greatest and most irregular thickening of the mucous membrane occurred. Upon the posterior and inferior surface of the trachea a large number of nodules, 7 mm. in height, smooth or slightly roughened, with broad, or in some instances constricted base, were found to extend 2½ cm. into the right bronchus. This fact, coupled with the disease of the mucous membrane of the right bronchus, occasioned great constriction of its calibre.

The rest of the bronchus contained long ridges of soft consistence, the substance of which projected when cut, and was white, but without any marked amount of fluid.

The microscopic examination of the nodules revealed their cancerous nature. They were composed of two elements, viz.: a reticulated stroma of connective tissue, and clusters of cells in the meshes of the stroma. These were small polyhedral or cylindrical cells, containing a distinct nucleus, with nucleoli and a small amount of cell-substance, lying next to the cells of the inferior layer of epidermis.

They were, without intermediate substance, connected with cylindrical prolongations from 0.04 to 0.08 mm. wide, closely resembling similar structures of cancer and cancroid, and exhibiting a well-defined contour, reminding one of an enveloping membrana propria, though such a membrane was certainly *not* present. In the peripheral layer the cells were of cylindrical form. These lay very close together in a delicate stroma composed of elastic fibres and connective tissue.

Although lying close together, the cells did not press upon each other, but were suspended lightly one from another, a condition easily seen by changing the focus of the microscope. The same morbid cell-elements were found in all the layers of the mucous tract, in the most superficial, directly under the epithelium, in the elastic layer, the fibres of which were pushed asunder, and most plentifully in the glandular layer, in which the glandular structures were entirely gone. The disease had extended through the submucous layer to the cartilage, the perichondrium of which was thoroughly infiltrated with the morbid products. The microscopic investigation proved the growth to be soft cancer of the mucous membrane, constituting a very rare case of primary cancer of the trachea and bronchia.

Arsenic as a Prophylactic in Rabies (*Correspondenz-Blatt*, August 1, 1872).—Dr. Ernest Guisan, in an inaugural dissertation presented to the faculty of Berne, states that though he has arrived at no positive conclusion, he believes that, as in cholera, the germ of the contagion in rabies is formed by one of the lowest fungi. The period of incubation extends, upon the average, over five or six weeks. The poison is then absorbed, spreads itself through the body by means of the circulation, and then multiplies indefinitely, producing ultimately irritation of the nervous centres, and especially of the medulla oblongata. Dr. Guisan then enters into the prophylactic treatment of the disease by means of arsenic, and gives the following clinical observations: "A man was bitten on the 24th of June by a mad dog, in the hand; a girl was bitten at the same time, and shortly after died from hydrophobia. Two days after the accident the man applied to Dr. Guisan's father, who cauterized the wound deeply with potash, and kept the wound open with cantharides. Minute doses of belladonna were given morning and evening up to the 18th of July, when the patient had rigors and pains in the body. From this time up to the 26th of July the symptoms of hydrophobia became gradually more and more expressed, in spite of repeated venesections and the use of calomel and opium. At this date, however, small doses of arseniate of soda were prescribed every four hours (0.003 of a gramme). On the 27th, marked amelioration of the symptoms was observed, which continued till, on the 30th, all danger had passed, and complete recovery took place." Dr. Guisan gives another case in which a rabid dog, between the 7th and 9th of June, bit thirteen persons in various towns of the canton of Freiburg. All were recommended to be treated with one-twentieth of a grain of arsenic morning and evening, as a prophylactic measure. Eight submitted to this prophylactic measure, and none were affected. Four declined, or were not allowed, to take the arsenic. Of these four, two remained unaffected, and two died. One began the arsenic treatment, but speedily left it off. She was attacked, but at a much later period, and died. Dr. Guisan recommends not only the internal employment of the arsenic, but that the wound should be dressed with it.

The Dementia and Hemiplegia of Syphilis. By Dr. M. H. Henry (*American Journal of Syphilography and Dermatology*, January, 1872).—There is a tendency at the present day to attribute obscure brain-disorders to syphilis; sometimes merely because the patient has had venereal disease at some period of his life, and sometimes because the disease can be traced to no other origin; but there has not been as yet a sufficiently careful study made of syphilitic lesions of the nervous system to place the subject on a thoroughly scientific basis. It is with a view of adding to the literature of this branch of medicine, and with the belief that careful clinical observations will bring "order out of the chaos of ideas that are now afloat regarding the etiology and pathology of brain-syphilis," that Dr. Henry has reported these cases.

The first case is one of "dementia," which occurred suddenly, two years after the patient had contracted the primary sore. In the mean time he had shown evidences of constitutional disease, for which he was treated by the author, and from which he had apparently recovered entirely.

During the course of the disease, facial palsy, together with strabismus, great impairment of vision, and partial loss of power in the legs, came on.

The patient was completely restored to health under the use of iodide of potassium. An interesting feature is the immense doses of the drug that were tolerated. For at least a month, three hundred grains of the iodide were taken every day, not only without inconvenience to the patient, except slight disorder of the stomach, which soon yielded to treatment, but he gained in flesh and strength day by day. The lesion in this case was supposed to be diffused gummy deposit at the base of the brain.

The other case was one of hemiplegia, with a well-marked syphilitic history. Death occurred on the seventh day after the seizure, which was sudden. At the autopsy, a gummy tumor, "as large as a pea," was found in the fissure of Sylvius, encircling the middle cerebral artery.

The Treatment of Dilatation of the Stomach by the Method of Kussmaul.—Dr. J. O. Affleck (*Edinburgh Medical Journal*, June, 1872) advocates this plan, which consists in the emptying of the distended organ by mechanical means,—the stomach-tube, with a pump or a siphon attached,—and washing it out with some medicated liquid.

The morbid condition, which may be due to the pressure of tumors, to thickening of the tissues about the pylorus, whether by cancerous growths, or by simple induration from chronic catarrh, or to the contraction of ulcers in healing, consists in a dilatation, either with or without hypertrophy of the muscular walls; hence the great bulk of the food taken is retained in the stomach, and, undergoing putrefactive and fermentative changes, becomes a source of extreme irritation and distress. Violent pain and heartburn, with eructations and vomiting, either spontaneous or provoked, of a brown-colored, offensively-smelling, strongly acid matter, are the symptoms. A pellicle containing torulæ and sarcinæ collects on the surface of the ejecta. The patient becomes emaciated and anæmic, feeble, sometimes œdematous, and may even die of starvation. Obstinate constipation is often attendant on this disorder, and the urine is scanty, alkaline, and loaded with phosphates.

Various plans of treatment have been proposed; such as giving only the smallest possible quantities of food; giving animal food only; antizymotics,—such as sulphurous acid, alkaline sulphites and hyposulphites, chlorine water, etc. The green iodide of mercury has been much used, also, in sarcinous vomiting.

In 1867, Prof. Kussmaul, of Freiburg, proposed to evacuate the stomach by means of the pump, and to wash out the organ with Vichy water. His first case was markedly relieved, and the plan was adopted in various Continental hospitals.

Dr. Affleck records two cases, one of which seemed to have been primarily a gastric catarrh, while in the other ulceration was present, in both of which Kussmaul's method was employed with great benefit. He remarks that the most favorable cases for its use are those of recent development, when no great changes of structure have had time to occur.

The objections made to the plan, none of which, however, have any real weight, are the annoyance to the patient of the passing of the tube; the risk of injury to the stomach; and the inconvenience of carrying out the treatment in private practice.

The Abortive Effects of Quinine (*Wiener Mediz. Presse*, No. 33, August 18, 1872).—In answer to a series of cases adduced to prove that quinine has a tendency to produce abortion, Dr. Bergely, of Kaposvar, Hungary, says, "Aside from its specific antiperiodical effects, quinia possesses a peculiar astringent and tonic influence upon nerve- and muscular fibres, and hence in atonic conditions of these tissues finds its most valued application." That quinine, however, possesses a specific influence upon the gravid uterus, he denies. In malarial regions, when abortion follows the administration of quinine, the malaria and not the quinine is

the cause of the abortion. In proof of this he says the effects of malaria are not only productive of anæmia, but of relaxation of all the tissues, and hence the uterus is unable to retain the fœtus.

In many cases of threatened abortion in women affected with malaria, he has averted the event by administering quinine, in the proper antiperiodic doses.

Respecting the effects of quinine in cases of retained placenta, he says that under certain circumstances it may induce expulsive contractions in the walls of the uterus, but he has found it useful only in cases where the retention is due to simple atony of the organ.

In conclusion, he says that quinine can have no specific and abortive effect upon the uterus, for, were such the case, abortion would occur much more frequently than it does in all malarial regions, where most of the pregnant females take large doses of the alkaloid to relieve their malarial evils.

The discussion is continued in the *Wiener Mediz. Presse*, No. 36, 1872, by Dr. Von Josch, of Klagenfurth, who says that, judging empirically, it seems evident that a large dose of quinine will produce contractions of the uterus in the third stage of labor, although we are entirely ignorant of the physiological action. But its use, as well as that of ergot, is superfluous in the expulsion of the placenta, and should be substituted by other and surer means.

Tetanus (*Allg. Militär-ärztl. Zeitung*, No. 37, Sept. 15, 1872).—Dr. B. Beck, surgeon to the Fourteenth Prussian army corps, says that tetanus occurred only forty-five times among seven thousand one hundred and eighty-two wounded German soldiers. It occurred more frequently among the French.

Aside from the individual peculiarities of the nervous system, the disease was caused by the presence of foreign bodies, splinters of bone, bad transportation, and, especially, exposure to *dampness* and *draughts of cold air*. The true nature of tetanus is still very obscure, and the theory that it is an ascending neuritis is not tenable, since in numerous dissections upon the cadaver, no traces of the products of inflammation have been discovered, neither have new growths of connective tissue been found in the brain or spinal cord, although fatty degeneration or extravasated blood has been found in the nerve-sheath. We must therefore content ourselves with the theory that tetanus is caused by an irritation of the spinal cord, producing its effect in a peculiar reflex manner. Of the forty-five cases already mentioned, thirty-nine proved fatal between the fourth and fourteenth days after the reception of the wound. Since art is powerless in these cases of disease, all the causative influences mentioned above must be most carefully counteracted. If operations are to be performed where joints are open and extensive laceration of tendons has occurred, they must be done at the first indications, for later they are useless. Since baths cannot be procured on the battle-field nor in temporary field-hospitals, the German surgeons in the late war depended upon morphia, curara, and chloral hydrate, the first of which proved itself to be the most beneficial.

Menstrual Epistaxis (Dr. Otto Obermeier, Charité, Berlin; *Virchow's Archiv*, volume lv. part 3, 1872).—A healthy, well-formed German servant-girl, twenty-four years old, was admitted, for temporary insanity, into the insane department of the Charité in Berlin. She stated in her lucid intervals that she had commenced to menstruate in her fifteenth year, with an attack of pain and excessive flow of blood from the genitals. This lasted only twenty-four hours; during the following forty-eight hours she suffered pain but had no hemorrhage. At the end of three days all symptoms disappeared, and the girl remained well until four weeks later, when the same pains returned, accompanied by vertigo, faintness, and bleeding at the nose, which lasted for three days. Since then these menstrual attacks have returned with regularity, and at each period she has lost about a cupful of blood from the nose, but at no time has any menstrual discharge from the genitals appeared. In March, 1870, this discharge of blood from the nose ceased, and in December of the same year the girl was delivered of a child. Six weeks after the delivery the epistaxis returned, accompanied by the former symptoms. This recurrence of symptoms lasted until August of this year, when they again ceased, and the girl supposed she was pregnant,—a fact which was soon confirmed by exploration. Among the rare cases of vicarious epistaxis, this one is especially worthy of note on account of the cessation of the menses at the time of conception, and the return of the same after the termination of pregnancy.

Excision of the Left Scapula.—Samuel Logan, M.D., New Orleans, La. (*Richmond and Louisville Medical Journal*, August, 1872), publishes a case of excision of the left scapula subsequently to resection of the head of the humerus of the same side. He is agreeably surprised at the degree of usefulness of the extremity after such an extensive removal of bone. The patient, male, aged 33 years, during convalescence from smallpox received severe blows on his shoulders, and shortly after began to suffer pain in the left scapulo-humeral joint, followed by caries of the head of the humerus and body of the scapula.

Three months after the operation the wound had almost entirely healed, with the following use of the limb: He could lift readily any moderately heavy article; could pull perpendicularly (lifting) 26 pounds, horizontally, 26½ pounds; by simply flexing the forearm (and not lifting with the body) he could raise 14 pounds; could place his hand on either ear or shoulder, but not on the back of the neck, and pass his hand over the whole of his forehead and face; he could not carry his hand behind his back, but could readily bring it so as to sweep over the whole chest and face. The cavity left by the operation was filled almost to the level of the surrounding parts with a somewhat hard mass of new deposit.

Vehicle for the Internal Administration of Chloroform (*Journal de Pharm. et de Chimie*, 1872).—Dr. G. W. Murdonck, having tried various formulæ proposed to facilitate the ingestion of chloroform, has found that some were difficult of execution, others contained sulphuric ether, and others again contained but little chloroform. He considers the best proceeding to consist in dissolving the chloroform in glycerin (1 : 3), which is effected with tolerable facility, and gives a very clear solution, pleasant to the taste, and with a strong odor of chloroform. This solution can be mixed in all proportions with water without the occurrence of any precipitation, though the odor is distinctly perceptible. In forming the mixture it is well to add the chloroform slowly, and to mingle the two thoroughly. It should be left at rest for twenty-four hours; at the expiration of this period a portion of the chloroform will be found to have collected at the bottom of the vase; this should be separated and mixed with an additional part of glycerin, when no further separation will occur. This mixture may be kept for some time without any loss of chloroform by evaporation.

Singular Case of Hemorrhage from the Bowels (*Medical and Surgical Reporter*).—A rare and important case is reported in the *Bulletin de Thérapeutique*, June 20, which throws light on some hitherto inexplicable cases of sudden death from intestinal hemorrhage. A man, 74 years of age, had enjoyed good health, except a tendency to constipation. One night

he was taken with intestinal hemorrhage, and died in a few hours. Only twice, and that about a month before, had he had slight attacks of a similar character.

A careful autopsy disclosed the only lesion to be an *erectile tumor*, the size of an almond, in the mucous coat of the duodenum. It was composed merely of an enlargement of the capillary vessels of the part, or so-called angioma. A slight ulceration at its edge had given rise to the hemorrhage which destroyed life.

The Physiological Dyspepsia for Starchy Food in Infancy. By Prospero Sonsino, M.D., of Pisa (*The Practitioner*, Sept. 1872).—If we examine the composition of milk, the proper food of the new-born and young infant, which with reason we may retain as the prototype of the complete aliments, we find in it, besides water and salts, the three organic groups of alimentary principles which concur in different manner to sustain the process of nutrition, viz. the group of albuminoid or *nitrogenized* principles, that of *fatty* principles, and that of hydrocarbonaceous principles. But it is remarkable that the latter are exclusively represented by a kind of sugar called *lactin*, which, with an insignificant modification, being converted into *glucose*, is rendered diffusible,—a substance which could almost be called a true nutriment in the signification given to this word by Corvisart; whereas the starchy principle, which is a conspicuous ingredient of the diet of the adult, and which needs an elaborate process of digestion to be converted into glucose, the material fit for absorption and diffusion, is not at all present in *any* milk. This circumstance of the composition of milk induces us to put the question, "*Is the easiness of digestion of milk in early life to be attributed to its being deprived of starchy principles?*" or, in other words, "*Is it the inaptitude to digest the starchy matter which in early life interferes with the complete digestion of all the aliments which include that material?*"

We have good reason to reply affirmatively to this question, and it follows that in infants there is what we may call a *physiological dyspepsia to starchy matters*, to which ought to be referred much, if not all, of the difficulty in the choice of the convenient food for infants.

It is convenient to examine what other considerations may confirm this suspicion of the indigestibility of starch in early life.

For this purpose it is of paramount importance to examine the peculiarities of the anatomical conditions of the digestive canal in the infant. It is known, in fact, that zoologists have established some differences in the anatomical characters of the digestive canal, which distinguish herbivorous from carnivorous mammalia; and that as to man, the anatomical conditions of his digestive canal, being between those of herbivorous and carnivorous, give evidence that he is neither exclusively herbivorous nor exclusively carnivorous, but omnivorous. Now, can we say the same thing as to the early infantile age?

Dr. Routh, who has dwelt much on this question, quoting Burdach, says, "It is remarkable that suction is the only faculty for the prehension of food which the child possesses at birth, and even this is soon lost if not practised. The jaws are not so constructed as to permit active movements, nor the gums to bear pressure. The hard palate is but little developed, although the cavity of the mouth is sufficiently wide. There is, moreover, no saliva secreted for the first two months, so that no species of preparatory change can take place in it, as, for example, in the conversion of starchy matters into sugar, through the agency of this fluid (saliva). The mouth is, therefore, merely an organ of transmission and suction. The lips are large, and the tongue and pharynx, uvula, and soft palate are well developed, to secure these ends. The stomach in infants is a small tube-shaped membrane, dilated in the centre, one extremity ending in the œsophagus, and the other in the pylorus, resembling in this character that found in carnivora through life. In position, also, it lies more parallel to the trunk; the large and small curvatures and muscular structures being but very little developed. The liver at birth is unusually large; the pancreas perhaps not more developed than the salivary glands; the intestinal tube is much shorter, and the large intestine approaches more nearly in its length to the small. The cæcum (in which, moreover, it is believed a sort of additional digestion occasionally occurs) is very small. The peristaltic motion is more rapid. All these are evidences that food taken will be kept for a shorter time in the canal, and therefore should be in the condition most favorable for digestion. Lastly, in no other of the mammalia is there, in the first periods of life, such a complete absence of teeth. In man they appear latest, and are longest in obtaining their full development. In fine, comparing these appearances with those observed in herbivorous animals, viz. well-developed salivary glands; compound stomachs, sometimes four in number; muscular gizzards, as in some birds; long intestines, large ileum, etc., it is manifest they are the exact opposites to what we find in young infants. As the child grows, the peculiarities which are permanent in herbivorous animals gradually present themselves. The stomach assumes a more horizontal position, the *valvulæ conniventes* become well developed, the peristaltic motion of the intestines becomes slower; in fact, all the changes calculated to retard the food in its progress, and thus to expose it more completely to the solvent juices for digestion, occur. All this proves indubitably that animal, not vegetable, food, is the proper diet for an infant." Routh's "Infant Feeding and its Influence on Life," etc., second edition, p. 75, London, 1863.

But let us see what is the principal difference of composition between animal food and vegetable food. Partly, that in the latter we find more materials refractory to any digestion; that in consequence a more elaborate power of digestion is needed to obtain the nutriment from it. We find, in the one and in the other, albuminous principles, fatty principles, saccharaceous principles; whereas *only starchy principles*, which constitute the principal ingredient of vegetable food, are not at all present in animal food, be it meat or any other tissue, or a product of the animal, as milk or eggs.

Therefore, the same physiological and anatomical arrangement that in infants gives evidence of its being not prepared for vegetable food, supports the conclusion that starchy matters cannot be well digested in infancy, and that there is really in infancy what may be called *a physiological dyspepsia for starchy aliments*.

Another valuable confirmation that starchy matters are not well digested by the infant, we have, lastly, in the very interesting observation made by a Frenchman, M. Guillot, who in the autopsy of a number of infants found a jelly-like substance present in the intestines, which to the test of the tincture of iodine gave evidence of containing a large quantity of unaltered starch. This fact is referred to both by Dr. West in his excellent general remarks on the diet of infants, being a chapter of his valuable work on Diseases of Infancy, etc., and by Dr. Routh, at p. 325 of the book already quoted.

Death from Ether (*Medical Record*, Oct. 1, 1872; by W. B. Dunning, M.D., Acting House Surgeon, Bellevue Hospital.)—John Stockander, a German saddler, unmarried, sixty-eight years old, was admitted to Ward thirteen of Bellevue Hospital, on August 2, 1872, suffering from a fracture of left femur, just below the trochanter. The patient was treated by a Buck's Exten-

sion until August 20, when it was decided to apply a plaster of Paris splint. In order to make sufficient extension, and at the same time prevent the pain of the operation, ether was ordered to be administered. The administration of the anæsthetic was slowly and carefully made, and after perhaps ten minutes the patient was fully under its influence and the operation begun. A few turns of the plaster had been made, when the patient's breathing was observed to be rather frequent and gasping. The pulse was, however, full and regular. The thorax was compressed two or three times, and the patient's breathing again became normal. As these symptoms not rarely occur during etherization, they excited no special alarm. The ether was, however, withheld from the patient four or five minutes, his respiration and pulse being normal. As he then began, however, to move about and his muscles were becoming rigid, the ether cone was again applied. In a minute or two, my assistant, who was giving the ether, observed the pupils to be dilating rapidly and the breathing to cease. His heart was still beating, however. The ether cone was of course immediately removed and artificial respiration was again used, and all the batteries obtainable in the hospital were put in operation in an effort to resuscitate the patient. His muscles occasionally responded by a spasmodic movement, but no breathing again occurred. The efforts at resuscitation were continued about forty minutes, until all response to the action of the battery had ceased.

Patient died about four P.M., and the autopsy was made at seven P.M. that same day, under direction of Dr. Delafield. Rigor mortis was marked. Blood was fluid. Brain and membranes neither anæmic nor congested. Trachea and larynx somewhat pale. Heart contained a little fluid blood, with a little atheroma at base of aortic valves. Lungs have old adhesions over both. Emphysema exists, and thickening of large bronchi. The lower lobe of right lung is œdematous, and its lower portion in a state of red hepatization. Rest of lung is normal and not congested. Liver is small and firm, containing a good deal of fluid blood. The other organs are normal.

The ether used was that made by Powers & Weightman. It has been examined by Dr. Squibb, of Brooklyn. He states that he "finds nothing in the character or quality of the ether to account for the death of the man, or even to aid in accounting for it." He adds, that in his "judgment the death of this patient is in no way attributable to either the quality of the ether, the quantity used, or the mode of administration, but that it is one of those accidents which, though of very rare occurrence under the careful use of ether, is inseparable from the condition of anæsthesia."

The quantity of ether used was about ℥vj.

Thoracentesis in Infantile Pleurisy (*Lancet*, Aug. 10, 1872; from *Bull. de l'Acad. de Méd.*).—In the course of the discussion still going on at the Paris Academy of Medicine on empyema, Dr. Roger, physician to the Hôpital des Enfants, had occasion to relate the results of his vast personal experience of empyema in children. Referring especially to the question of thoracentesis, and basing his opinion upon a great number of facts which he related, Dr. Roger thus tersely summed up his conclusions: Operate *always* in cases of *purulent* pleurisy in children; operate *rarely* in cases of abundant serous effusion; *never* operate in cases of slight effusion.

Therapeutic Actions of Muriate of Lime.—Dr. Warburton Begbie (*Edin. Med. Jour.*, July, 1872), in an able memoir read before the Medico-Chirurgical Society of Edinburgh, after alluding to Cazenave's use of this article in lupus, says, "This much I am able to affirm, that its alterative powers in certain cases of cutaneous eruptions intimately connected with syphilis, more especially lupus exedens and non-exedens, and in local psoriasis, also in some instances of ozæna and chronic tonsillitis, have appeared to me quite unmistakable. The dose is from ten to twenty grains in solution."

Carbolic Acid for Injecting in Hydrocele.—Dr. P. E. Sandidge, of Edmonton, Ky., reports in the *American Practitioner* a case of double hydrocele, operated on by him in 1868, with the usual injection of tincture of iodine. In April, 1871, the trouble having returned, he operated again on the right sac, injecting f℥ij of Calvert's solution No. 5.* In January, 1872, he repeated the procedure on the left side, and thinks he has obtained a perfect cure, no reaccumulation having taken place at the end of six months.

Telegram from the Convention of German Naturalists and Physicians (*Wiener Mediz. Presse*, August 18, 1872).—"Leipsic, 15th August, 1872. In the scientific duel of to-day, between Stricker and Cohnheim, four professors, chosen as umpires, decided in favor of the assertions and correctness of the preparations of the former, while the endeavors on the part of Cohnheim to set aside the methods of investigation and the scientific results connected with the 'Vienna school' were condemned with strong protest."

MISCELLANY.

Liberality and Bigotry in Medicine—Consultations with Homœopaths.—The *Pacific Medical and Surgical Journal*, October, 1872, contains the following excellent remarks: "There is a vast amount of humbug current in the world under the name of liberality, as well in medicine as in politics, morals, and religion. Restless mortals, impatient of restraint, and soured by disappointment and personal grievances, declare war against some established code or custom, and denounce all opposition to their revolutionary notions as illiberal and bigoted, and imagine themselves to be doughty champions of progress and reform. In turning over the hotch-potch of periodical literature issued in the name of medicine, one often notes the footprints of these iconoclasts, some of whom have undertaken the task of breaking down the barriers between what they consider as medical sects, and establishing a grand fraternity which shall embrace in one loving circle all parties, creeds, and schools. It is very easy to make a show of charity by pleading for a union of this kind; and it is alike easy to attach the semblance of illiberality to physicians who refuse professional intercourse with those of opposite schools. The enemies of regular medicine have made much capital out of the enforced prohibition of consultations with homœopaths. Under the specious idea of accepting good wherever it may be found, they defend what they are pleased to consider a liberal intercourse with sectaries of all kinds. And there are many persons in the world, very sensible in other respects, who can see nothing but bigotry and intolerance in the refusal of regular physicians to consult with sectaries who proclaim, as the first article of their

* See the number of the *Times* for August 15, p. 436.

faith, that the regular system of medical practice is murder. The popular notion is that the barrier between the regular profession and others is one of jealousy and personal feeling, built up by the profession. The truth is that the barrier is in no wise personal, but is founded on common sense and propriety, and on a proper regard for the welfare of the sick. Is it not worse than mockery to hold a consultation over a sick man with a practitioner who tells me that my treatment is irrational and injurious? What compromise can there be between two systems *directly opposite* to each other? A true homœopath cannot adopt my system, or any portion of it. To do so would prove him to be an arrant hypocrite. There are some who practise either system, according to circumstances. They are as honest as would be a clergyman in preaching to suit his hearers or his pocket, Romanism to Catholics, Socinianism to Unitarians, Buddhism to Burmese. What would be thought of a Catholic Bishop and a Jewish Rabbi being required, in order to illustrate religious toleration, to meet together and join in administering the last rites of religion to a dying man? The most they could say in answer to the request would be, One at a time. And it is just as absurd to call on a regular physician to confer professionally with a homœopath. The refusal implies no personal hostility,—no sentiment incompatible with the second table of the Law. It is but a declaration of consistency and honesty,—a refusal to sacrifice principle to policy,—a refusal to act the hypocrite with another hypocrite over the bed of sickness."

An eccentric character died recently in St. Louis, Missouri, who is described by a correspondent as follows: "There died in this city yesterday, of smallpox, an eccentric old man, named Hotchkiss, generally known as the 'Snapping Doctor,' the 'Rag Doctor,' and the 'Dirty Doctor.' Hotchkiss was an illiterate man, who claimed to have supernatural powers of healing the sick through the agency of animal magnetism, and extraordinary stories of miraculous cures of chronic diseases by him are in circulation among the ignorant people who believed in him. He was a very old man, and claimed to be one hundred and forty years of age, with an expressed determination to live until the second coming of Christ. He was not only a very old, but he was also a very dirty, man. It is said that for twenty years he has not washed himself, and his apartments reek with filth. Dr. Hotchkiss was a queer-looking old fellow. He wore a long gown and a red fez cap. His sharp, haggard features, begrimed with the accumulated dirt of years, his brilliant black eyes, restless with the fires of insanity, and his long, matted, snow-white beard, gave him a weird, unearthly look. His extreme age cannot be doubted, though it is hardly probable that he was 140."

The Pathological Society of Philadelphia.—The annual meeting of this society was held on the 24th ultimo, at which time an election for officers took place, and reports of the officers were made. The number of specimens presented during the past year (over one hundred), as shown by the report of the Secretary, indicated that the work of the society had been maintained, and that the interest in pathological research was unabated. The experience of the past two years has demonstrated fully the wisdom manifested in the organization of the Committee on Morbid Growths.

The work performed by this committee has been of the highest order, and has greatly increased the interest in the society.

Dr. J. H. Hutchinson was re-elected President. Dr. J. Ewing Mears, who has served as one of the Secretaries for three years, resigned, and Dr. D. Murray Cheston was elected to fill his place. Drs. W. F. Norris and Wm. Thomson were compelled by professional engagements to resign from their positions on the Committee on Morbid Growths.

Advice to Medical Witnesses.—Dr. Thad. M. Stevens (*Transactions of Indiana State Medical Society*) gives some good counsel to medical witnesses: "Each witness having a well-digested knowledge of all that is known upon the subject, should upon the main examination give a clear statement of the case, devoid as possible of technicalities, and his opinion with reference thereto from personal observation; or if it be upon a hypothetical case, answer if the hypothesis be clear, but, if it be not, insist upon its being modified or refuse to answer. Never answer a categorical interrogation when it needs interpretation or division into parts. And as to cross-questioning in general, 'do not permit the attorney to force you into answering questions that you are aware cannot be made clear or will mislead.' Such a position is the privilege of the medical witness, and never, until it is recognized, will the subject be upon its right footing."

The managers of the Pennsylvania Hospital, in order to extend its benefits to a large class who, although requiring medical aid for which they cannot afford to pay, do not absolutely need admission into an hospital, and indeed prefer remaining with their families, have determined to open a department for "out-patients," in which those applying will receive the necessary medical service or surgical treatment. With this purpose the managers, at their stated meeting on the 28th of October, elected the following-named physicians and surgeons to take charge of out-patients, viz.:

Physicians, Drs. Morris Longstreth, Jos. G. Richardson, and Joseph J. Kirkbride. Surgeons, Drs. Chas. T. Hunter, Thomas H. Andrews, Elliott Richardson, and H. Earnest Goodman.

This department is now open at the hospital on Eighth Street, below Spruce, daily (Sundays excepted), from 10 to 11 A.M.

A Floating Hospital for Chest-Diseases (*Wien. Med. Presse*, September 1, 1872).—To our numerous land hospitals low down on the sea-coast and high up in the mountains, is to be added now a new institution with very many advantages, but with the single disadvantage of being only for the benefit of the rich. Dr. V.

Wallendorf establishes a hospital for chest-diseases this winter on a screw propeller, which is to journey out late in the fall from Cuxhaven beyond Gibraltar and along the coast to Malta, if the weather is fair, and to return again in the beginning of April. The vessel is to be specially prepared for its purpose, is to have a competent physician on board, and the patients are to be allowed to make land-sorties as long as possible in several stations of mild climate.

Dr. Brown-Séquard having resigned the chair of Comparative and Experimental Physiology in the Parisian Faculty of Medicine, Dr. Vulpian has been appointed in his place.

This makes a vacancy in the chair of Pathological Anatomy, which will probably be filled by the nomination of Dr. Charcot, the well-known physician of La Salpetrière.

The Paris correspondent of the *Lancet* of October 12, who gives the above items, announces the death of Dr. S. Duplay. [We think this must be a mistake; Dr. *J. F.* Duplay's death having been mentioned in some of the French journals. M. Simon Duplay is one of the editors of the *Archives Générales*, and a man whose loss would have been at once and widely noted.—Ed. P. M. T.]

Midwifery in Russia.—It is stated that the Emperor of Russia has just issued a ukase ordering the immediate establishment at St. Petersburg of a school to train midwives, as up to the present time no such institution had existed anywhere in that immense empire. The curious part of the matter, however, is that the direction of this school is placed in the hands of the Minister of War, who, under date of the 10th of August, published the regulations of the institution and the programme of the studies. This anomaly results from the fact that the new school is subordinate to the Academy of Medicine and Surgery at St. Petersburg, which is also under the control of the War Department.

Poisoning by Vanilla.—A physician in Worcester County, Mass. (*Boston Medical and Surgical Journal*, August 1, 1872), in speaking of cases of poisoning by vanilla flavoring, stated that in his own family evident and violent poisoning from a similar cause recently took place. Five members of the family were affected, all of whom had partaken of custard flavored with vanilla, while two who had not eaten escaped. The symptoms were severe diarrhœa, with violent pain in the lower abdomen, without much gastric disturbance.

Medical Rank in the Navy.—The *Naval Register*, recently published, gives the following numbers and rank of the Medical Staff: 15 Medical Directors, with the relative rank of Captain; 15 Medical Directors, with the relative rank of Commander; 50 Surgeons, with the relative rank of Lieutenant-Commander; 25 Passed Assistant Surgeons, with the relative rank of Lieutenant; and 52 Assistant Surgeons, with the relative rank of Master.

Among the "volunteer officers" are 2 Acting Passed Assistant Surgeons and 11 Acting Assistant Surgeons.

The Academy of Natural Sciences.—The cornerstone of the new building for the Academy of Natural Sciences was laid on Wednesday, October 30, at noon, at the southeast corner of Race and Nineteenth Streets. Addresses were made by Dr. W. S. W. Ruschenberger, Prof. J. Aitken Meigs, and Prof. H. C. Wood, Jr. It is proposed to erect at present one wing of the building.

The following statement is from the New York telegraphic advices of a recent daily paper: "One Dr. Will was found guilty of malpractice yesterday by ignorance in treating a fractured hand so as to cause mortification, and subsequent loss of the hand. Five thousand dollars damages were awarded."

Dr. R. Angus Smith says that the air of houses should not contain carbonic acid enough to give a precipitate when a ten-ounce bottleful is shaken with half an ounce of clear lime-water.

The retirement of Dr. J. M. Foltz, late Chief of Bureau of Medicine and Surgery, U. S. Navy, has placed Dr. J. C. Palmer in that position.

Mortality of Philadelphia.—The interments reported at the Health Office for the week ending Nov. 2, 1872, were 264; of which 138 were of adults, and 126 of minors. Among the causes assigned were:

Consumption of the Lungs	43
Other Diseases of the Respiratory Organs	30
Diseases of the Circulatory Apparatus	16
Diseases of the Brain and Nervous System	34
Diseases of the Digestive Apparatus	15
Zymotic Diseases (2 from Smallpox)	21
Typhoid Fever	7
Cholera Infantum	1
Casualties	7
Intemperance	2
Debility (including "Inanition" and "Marasmus")	28
Still-born	16
Old Age	8
Suicide	1

OFFICIAL LIST

OF CHANGES OF STATIONS AND DUTIES OF OFFICERS OF THE MEDICAL DEPARTMENT U. S. ARMY, FROM OCTOBER 22, 1872, TO OCTOBER 28, 1872, INCLUSIVE.

Horton, S. M., Assistant-Surgeon.—Granted leave of absence for eighteen days, to take effect on arrival of Acting-Assistant Surgeon Buffington at Fort McKavett, Texas. S. O. 184, Department of Texas, October 17, 1872.

Monroe, F. Le B., Assistant-Surgeon.—Assigned to duty at Raleigh, N. C. S. O. 224, Department of the South, October 19, 1872.

Lauderdale, J. V., Assistant-Surgeon.—Relieved from duty at Fort Wood, New York Harbor, and assigned to duty at Fort Hamilton, New York Harbor. S. O. 201, Department of the East, October 21, 1872.

King, W. H., Assistant-Surgeon.—Granted leave of absence for thirty days, with permission to apply at Headquarters, Military Division of the Missouri, for an extension of thirty days. S. O. 169, Department of the Missouri, October 19, 1872.

Harvey, P. F., Assistant-Surgeon.—To report at St. Louis Depot, Mo., to accompany recruits to Texas, and on completion of this duty to join his proper station. S. O. 259, Headquarters of the Army, October 19, 1872.

Ewen, C., Assistant-Surgeon.—Granted leave of absence for four months. S. O. 262, War Department, A. G. O., October 23, 1872.

SATURDAY, NOVEMBER 16, 1872.

ORIGINAL LECTURES.

CLINICAL LECTURES

ON PROLAPSE OF THE WOMB.

BY WILLIAM GOODELL, M.D.,

Physician-in-Charge of the Preston Retreat; Clinical Lecturer on the Diseases of Women and Children in the University of Pennsylvania.

LECTURE I.

THE term *prolapse of the womb*, in its primary and strictly etymological sense, means the displacement of the womb as a whole by descent. A wider meaning has, however, been loosely given to it, partly because our nomenclature does not keep abreast with the times, and partly because it is not easy to give up a term firmly established by long use. Three widely different affections are now included under it, viz.: (*a*) A simple descent, or settling down of the womb. (*b*) A hypertrophic elongation of the infra-vaginal portion of the cervix. (*c*) A (so-called) hypertrophic elongation of the supra-vaginal portion of the cervix. In its present comprehensive sense, then, the term *prolapse of the womb* has come to signify a condition of that organ in which the *os tincæ* is found lower down than natural, the position of the fundus being practically disregarded. Apart from the violence thus done to language, there is questionable propriety in including under one general name three distinct lesions, simply because they happen to have one symptom in common.

In the simple prolapse of the womb,—which should more properly be called a substantial descent of the womb,—that organ as a whole, together with its furniture of tubes, ovaries, and ligaments, merely sags down, dragging with it the vagina and the bladder. The degree of displacement being proportioned both to the weight of the prolapsing body and to the relative relaxation of its supports, the womb will be found either more or less low down in the vagina, or else wholly extruded from the vulva. By many writers, the transitional stages of descent while the womb is yet within the vagina are included under the term *prolapsus uteri;* but when the descent is complete, and the womb wholly or in part outside of the vulva, the condition is called *procidentia uteri.* I must, however, warn you that these distinctive names have not been adopted as such by the profession at large; for by some they are employed interchangeably, as if they were synonyms, and by others in a reversed sense. The terms *complete* and *incomplete* would, therefore, be far more acceptable.

Studies from life quicken our apprehension far better than diagrams or verbal descriptions, and I shall therefore illustrate this form of displacement from one of our patients. This tall, thin woman is unmarried, and, although over sixty years old, is obliged to work hard for a living. Five years ago she began to suffer from a leucorrhœa, from dragging pelvic pains, and "bearing down" sensations. These symptoms had lasted for a few months, when one day, as she was in the act of lifting a scuttle of coals, "something gave way," and with a sudden pang of pain, her womb jutted out from the vulva. At first, after being replaced, it would stay so for one or two days; then, only for a few hours; but now, as long as she is on her feet, it hangs outside of her body. After getting into bed she is always able to push it back into the vagina, where, unless she coughs, it remains until morning. Of course, by this complete descent of the womb, all her former sufferings have been heightened; whilst in addition she now experiences difficulty in emptying her bladder, and strains much at stool.

As I expose the parts, you see a pyriform tumor hanging from the vulva. At its apex there is an opening—the *os externum*—into which I now pass up this sound to a distance of not quite two and a half inches. Now, since I can feel the tip of the sound outside of the vulva, and can with my fingers also define in the tumor the whole outline of the womb; and since a rectal examination informs me that the womb and vagina have vacated the pelvis, there can be no doubt that we are dealing with a case of complete prolapse, of true hernia, of the womb. The vagina, being of course completely inverted, as much so as a stocking turned inside out, constitutes the hernial sac; but the weight of the womb has not been sufficient to smooth out its rugæ. I wish you particularly to note the fact that the womb is retroverted and somewhat retroflexed. This results necessarily from the mechanism of descent, whenever the womb is the primarily prolapsed organ. For, since the womb is, as it were, slung at its middle, viz., the os internum, by its attachment to the bladder, it follows that in its descent the fundus must hug the sacrum, and describe the arc of a circle around the internal os as the centre of motion. Further, since the fundus is the heavier end of the suspended body, and also is forced down by the bulging in of the rectum into the vagina during the act of defecation, whilst the cervix is braced against the pubes or the neck of the bladder, some degree of bending will usually ensue. In fact, a retroversion or a retroflexion is but a modified form of prolapse, and must perforce precede the extrusion of a primarily prolapsed womb.

This simple form of prolapse is very generally the result of senile atrophy, and is therefore far more commonly found in old women. The pelvis has lost its padding of fat; the lax and wrinkled vagina no longer holds up the womb; the retentive power of the abdomen has been weakened by the absorption of the fat-packing in the omentum and in the abdominal walls. By the general decrepitude of old age, or by the muscular debility from disease, the woman's figure becomes altered. Her spine loses its sigmoid shape, her shoulders droop, and her chest bends forwards. Hence, the axis of the superior strait, instead of striking a point on the abdomen below the umbilicus, tends now to coin-

cide with the axis of the trunk. As a consequence, the intestines crowd down into the pelvis, and their weight is spent, not upon the pubic bones and the adjacent portion of the abdominal wall, but directly upon the womb, which now no longer lies under the shelter of the sacral promontory and of the lower lumbar vertebræ.

In younger women there are other causes which bring about this form of prolapse. For instance, those which increase the weight of the womb, such as congestion, subinvolution, and the presence of a polypus or of a fibroid tumor; those which weaken the lower supports of the womb, and shorten and straighten its line of descent, such as a relaxed vagina, and perineal lacerations; those, finally, which produce succussion or compression from above downwards, as a chronic cough, long-continued vomiting, tight-lacing, the wearing of skirts supported from the waist, and last, not least, the prolonged use of the obstetric binder, under the mistaken notion that it preserves the shape. Again, there are acute cases of prolapse from sudden jars, or from abrupt abdominal pressure.

This form of prolapse was deemed almost the only one until Huguier, in 1859, contended that so far from being a common form, it was an exceedingly rare one, and especially so when compared with that caused by a hypertrophic elongation of the supra-vaginal portion of the cervix. As you grow, and as knowledge grows, you will often be constrained to strip off even the poor tatters of some traditional belief; but I cannot yet ask you to adopt Huguier's opinion, supported though it is by many careful observers. My own observations teach me that the simple prolapse of the womb is by no means an infrequent affection of women—preferably of old maids—who have passed the climacteric, or who have been unbraced by chronic ailments. Nor have I failed to find it in younger subjects; although in such cases, either from imperfect involution after labor, from inflammatory action, or from subsequent derangements of circulation in the pendent mass, and also from friction and exposure to the air, there is usually some degree of hypertrophy of the womb, in its totality, however, —fundus, corpus, and cervix,—and not in one portion to the exclusion of another.

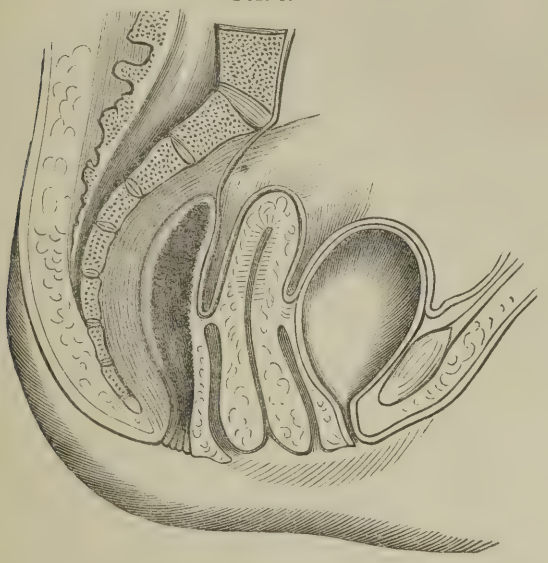
The indication in the treatment of this poor woman is clearly to return the womb and keep it in its place. As the perineum is intact, I think this can be done by Hodge's pessary or by some one of its modifications, which acts by restoring the posterior wall of the vagina and by propping up the fundus. At the same time I shall enjoin her to keep the contents of her bowels soluble, to avoid the lifting of heavy weights, to wear loose dresses, and to support her underclothing by shoulder-straps. Should the floor of the pelvis prove too slack to sustain this or the ring pessary, I shall try one which has an external base of support, such as Cutter's or Harlow's. Were her womb hypertrophied or otherwise diseased, in addition to the use of the pessary a special treatment should be addressed to these complications. Had she a torn perineum it would be well not only to restore it, but, by prolonging the incisions, to narrow still more the outlet of the vagina. This operation will of itself temporarily prevent the extrusion of the womb; but it can give permanent relief only when it furnishes to the pessary a firm base of support. To maintain an erect carriage, and to restore the sigmoid curve to the spine, a brace with a pad over the lumbar vertebræ is said to answer well; but with this I have no experience whatever. In general, whenever the prolapse is incomplete, and dependent, as it then usually is, upon some congestive or inflammatory condition, begin your treatment, not with pessaries, but with the usual remedies for such lesions. By removing the cause you remove also its consequences; but when foiled in this, then, and only then, may you resort to mechanical means.

In the second variety of prolapse,—that from a *hypertrophic elongation of the vaginal portion of the cervix*,—an entirely different condition obtains. Through nutritive activity this portion of the cervix becomes larger and much longer than natural; and although by its increased weight it usually drags down the body of the womb somewhat, yet this is so unessential a sequence that the affection has been termed "prolapse without locomotion of the fundus." In this variety, the cervix so rarely attains to a length greater than that of the vagina that, in our clinic, we have not yet met with an example in which the os tincæ showed itself outside of the vulva. You are, however, all familiar with that modified form of it, the conical cervix, which is interesting from its bearing upon dysmenorrhœa and sterility. Whenever the vaginal portion of the cervix is so long as to protrude from the vulva, it is, as a rule, either a congenital condition or an exaggeration of a congenital condition, and is therefore found in nulliparæ. In child-bearing women, through metritis from the contusions of repeated labors, the vaginal portion often takes on an hypertrophy, but this is then less an elongation than a general increase in every direction. There is yet another form of hypertrophic elongation which involves one lip of the os, usually the anterior. The prolongation becomes proboscis-like, and, from its resemblance to the snout of the tapir, has gained the name of *tapiroid*. All these acquired forms of hypertrophy are usually traceable to the traumatisms of labor, or to defective involution.

From the diagram (Fig. 1) you can see that the diagnosis of these affections is not difficult. Their character is sufficiently marked by the unnatural length of the uterine cavity and by the absence of vaginal invagination and of vesical prolapse. The tapiroid cervix may possibly be mistaken for a polypus, but, as the remedy in each is the same, no harm could happen. In all the varieties of hypertrophy attended by elongation, the redundant portion of the cervix when troublesome must be cut off. For this purpose the scissors, the écraseur, and the galvano-cautery, have each its advocates. The risk from hemorrhage is less when the latter instruments are used; but the scissors offer the advantage of a cleanly incised stump which the operator can cover by sliding over and stitching together the edges of the surrounding mucous membrane. Healthy tis-

sue being thus substituted for unhealthy, there can be no return of the disease, and further, the wound will sooner heal. For the details of this operation, I must refer you to Dr. Sims's classic work upon uterine surgery.

Fig. 1.



Let me here warn you against performing at your office this, or any other cutting operation upon the cervix or the vaginal tract. A smart hemorrhage is pretty sure to follow, either then and there, or else after the ride home; but, with your patient in bed, you can always control it by astringents or by the tampon. I shall not soon forget a scrape of this kind I once got into, by snipping off several clumps of venereal warts—I have been shy of them ever since—from the vagina of an office-patient. The bleeding resisted every astringent within reach, and as she resisted harsher remedies, I was glad enough to be able to staunch it with a tampon. What with the fright and the pain, there was no getting my patient home; she lay on my sofa the better part of a day; and that, to say the least, was not agreeable.

ORIGINAL COMMUNICATIONS.

A FATAL CASE OF PURULENT AURAL CATARRH.

BY GEORGE C. HARLAN, M.D.,
Surgeon to Wills Ophthalmic Hospital.

T. M., a strumous girl, twenty-two years of age, had been subject since early childhood to occasional attacks of pain in the left ear, with slight discharge, but they had never been considered serious, and but little attention had been paid to them.

When I was called to see her, on the 23d of December, there was violent pain in and around the ear, and distressing tinnitus. The watch was heard on contact only. The meatus was nearly closed by swelling of its lining membrane, rendering any examination by the speculum impossible.

She was ordered frequent syringing of the meatus with warm water, poultices over the ear, leeches to the mastoid process, hot foot-baths, and anodynes; and calomel was administered until her gums were slightly touched.

On January 9 the pain was still violent, and some tenderness and swelling over the mastoid were noticed. Her strength and appetite were failing. Quinine, wine-whey, and beef-tea were ordered, and an incision about an inch long was made over the mastoid through the periosteum.

On January 14 the incision, which, after discharging a little pus, had closed, reopened, and there was a free discharge through it and from the meatus. The pain was much relieved, and the watch could be heard at 1″.

January 16.—The discharge was quite copious, and the pain in the ear and tenderness of the meatus had disappeared; but she complained of violent pain in the forehead, temples, and top of the head, and there were nausea, vomiting, and sleeplessness. The mind was clear, the pupils active and vision undisturbed, and there was no paralysis of any of the cranial nerves.

January 18.—The swelling of the meatus had subsided sufficiently to enable me to discern by the speculum and mirror that the membrane was destroyed, and that a rounded polypus with a broad base was attached to the upper wall of the tympanum just within its anterior border. This was removed with Wilde's snare and the polypus forceps, and a cheesy matter was washed from the tympanum.

As a means of diagnosis, the left pupil was dilated by atropia and the fundus examined by the ophthalmoscope.

The examination revealed a most beautifully-marked optic neuritis, or, more correctly, the "choked disk" described by Jackson and Allbutt. The disk was œdematous, congested and much swollen, its arteries contracted, its veins engorged and its margins obscured, and there were small extravasations of blood upon its surface. The rest of the fundus was normal. Near vision was not carefully tested before the action of the atropia, but, even afterwards, she could readily tell the time by a clock at the other end of the room. Free leeching at the temple and mastoid was ordered.

January 21.—The pain had been much less severe, and was confined principally to the occipital region. She complained of double vision, and the external rectus of the left eye was found to be completely paralyzed. The fundus of the right eye was examined, and the disk found to be in the same condition as that of the left. Vision was tested with fine print, and found to be excellent. Iodide of potassium and mercurial inunction were ordered, and blisters applied to the temple and occiput.

January 25.—The external rectus of the right eye was paralyzed. The pupil was still active, and there was no other paralysis of motion or sensation. The engorgement and swelling of the disk was much increased; its position could be recognized only by the point of emergence of the veins. Vision was still good.

January 28.—The patient died, apparently from exhaustion. There had been no delirium or coma, and she spoke intelligently a few minutes before death.

Dr. Thomson, who saw the case with me, kindly assisted at the post-mortem examination. As it was made with the partial and conditional assent of the friends, early on a winter morning, in a bitterly cold room and with a member of the family standing guard at the partly-opened door, it was not so prolonged or thorough as we should have liked it to be.

The veins beneath the scalp on the back part of the head were much engorged, bleeding freely when cut. The membranes of the brain were highly congested, but there was no effusion. The brain-substance showed very

few vascular points on section, and was scarcely at all altered except the middle lobe of the cerebrum on the left side, where a large abscess was found, containing more than an ounce of greenish pus, and resting on the temporal bone, from which it was separated by the membranes. In these, however, there was a small opening.

The brain around the abscess was slightly softened, but not congested. There was a thick deposit of lymph on the upper surface of the petrous bone, but no pus. On removal of the lymph the bone was found carious beneath it.

The temporal bone was removed, and macerated for further examination. It was then found that nearly half of the roof of the tympanum, from the entrance of the Eustachian tube backwards, was destroyed. The opening from the tympanum to the mastoid cells was very much enlarged, and the upper wall of the horizontal portion of the cells was carious and contained several large holes. The upper and posterior wall of the bony meatus was "honey-combed," and several small openings communicated with the mastoid cells. The mastoid process was very imperfectly developed, and the vertical cells were not formed.

There are several points in this case that are worth considering.

In the first place, it adds one more to the many recorded warnings against neglecting "a slight discharge from the ear," and allowing the disease to progress year after year until the bone becomes carious. The wonder is, that this result is not more frequent. When it is once established, the patient's life henceforth hangs by a thread. An exposure to cold or a slight blow upon the ear may at any time light up a meningitis or cause a cerebral abscess. Death has also often resulted without any affection of the brain, from pyæmia, with metastatic abscess in the lungs, or joints, or elsewhere. The greatest protection of these cases is in the free discharge of pus from the external meatus, as the membrane is always partially or wholly destroyed. My patient was deprived of this by the obstruction of the polypus, and the great swelling of the meatus.

This subject has an important bearing upon life-insurance, and some English companies decline to consider the case of an applicant who has a chronic discharge from the ear.

Secondly, in regard to the treatment.—I must confess that I should have recorded the case with more satisfaction if, instead of contenting myself with a deep incision over the mastoid, I had trephined the bone in a comparatively early stage of the disease. But, as reported mistakes are often more instructive, and always more rare, than reported successes, I publish it in the hope that it may prove a lesson to others, as it has been a very impressive one to me.

The case, however, was by no means a plain one. There was no positive proof of the presence of pus at the commencement, and afterwards I was misled by the amelioration of the symptoms; while the active pupils, and the absence of paralysis, fever, or mental disturbance, left me in doubt whether the intense pain might not be attributable to neuralgia, to violent attacks of which the patient, an hysterical girl, had long been subject.

Thirdly.—The ophthalmoscopic examination affords an illustration of the great value of this means of diagnosis in cerebral disease. Though this use of the ophthalmoscope has been urged with great earnestness and ability by Hughlings Jackson and others, it is not yet so general, in this country at least, as it should be. Even ophthalmic surgeons are, perhaps, too prone to forget that perfect vision is not positive proof of a normal fundus.

Fourthly.—The existence of such extensive disease of the brain with no other subjective symptoms than pain, exhaustion, and occasional nausea, is remarkable.

Fifthly.—The paralysis of both external recti, without any other paralysis, is unusual, but the examination was not sufficiently minute to afford even a suggestion of its cause.

TWO SURGICAL CASES.

BY WILLIAM C. KLOMAN, M.D.,
Baltimore.

E. S., a boy of about eight years of age, while playing with some pennies which had been given him, put one into his mouth, and accidentally swallowed it. He is a German boy, unusually dull of intellect, and gave a very unintelligible account of his sensations. Upon being questioned, he was not certain whether he had swallowed the cent or not, but said he felt pain in his breast—"there!" pointing to his left side, below the region of the heart. Upon looking into his throat as far as possible, and seeing nothing unusual, I took it for granted that if he had swallowed the coin it had passed into his stomach, and in due course of time would be voided per anum. So I advised that he be fed plentifully with mush and milk, and that a dose of castor oil be given him the next morning. His bowels were moved copiously in consequence on the following day, but nothing was seen of the coin. I recommended patience, strictly enjoining that every evacuation be carefully examined, and thus several days passed without my hearing from him. On the sixth day after the cent was swallowed, I was sent for, and was told that the boy complained more than ever of pain in the region above spoken of; that he could scarcely swallow, and had no appetite; that he had had a stool every day, but that no coin had been found. The boy insisted that it was lodged in his throat. I again examined his throat, but could see nothing unusual. I then determined to get one of the probangs with a movable joint at one end and a piece of sponge at the other, such as are used for extracting coins or other foreign substances from the œsophagus. I pressed the end with the movable joint, and met with some resistance near what I supposed must be the cardiac orifice of the stomach; with a little manœuvring, I fixed the probang upon some object, and it required some degree of force to withdraw the instrument. When I did withdraw it, I brought up a large old-fashioned cent of the year 1818. It was covered with mucus; upon one edge the mucus was somewhat bloody, and there were some shreds of

food adherent to it. The boy was perfectly relieved, no symptoms following.

C. M., a boy aged ten years, while playing in an old burial-ground, fell upon an iron railing, one of the points penetrating the abdominal wall at a point one-half inch towards the median line from the anterior superior spinous process of the ilium. The point of the iron was slightly bent, forming a hook; and in disengaging the boy from it, a piece of omentum about three inches long was dragged from the wound and considerably lacerated. I was immediately sent for, and found the omentum still bleeding. The boy looked pale and frightened; his pulse was small and frequent, but there was no vomiting. I had the usual difficulty in attempting to reduce the protruded omentum, but succeeded with the aid of chloroform. Instead, however, of returning the entire piece of omentum, I thought it best to pass a ligature around the bleeding and lacerated portion, with the view of removing it the next day. I passed the ligature around it, close to the integument, and tied it. The portion thus constricted was about one inch and a half long, and filled up the wound entirely. I then simply covered it with a cloth wrung out of warm water, enjoined complete rest in the recumbent posture, the room to be kept darkened and quiet, and the patient to be kept upon very low diet, and that only fluid. I ordered him one-half grain solid opium at once, five grains hydrate of chloral in two hours, if not asleep; the two remedies to be alternated every second hour, unless he fell asleep.

The following day my patient expressed himself as feeling comfortable; his bowels had not been moved, but he had passed his urine. I removed the ligated portion of omentum with scissors. Adhesion had taken place, and the wound was hermetically sealed. I continued the treatment. On the third day, there being no symptoms of inflammation, I lengthened the intervals between the remedies to three hours, still enjoining rest and quiet. On the fourth day he had a copious evacuation from his bowels, and, there being no symptoms of inflammation, I discontinued all remedies. The wound looked healthy, granulating finely, and he recovered without the slightest sign of peritonitis.

HÆMATOMA OF THE EAR.

BY WILLIAM KELLER, M.D.,

Philadelphia.

HÆMATOMA of the ear (hæmatoma auriculæ, othæmatoma of authors) is a tumor, which grows from the inner side of the concha auriculæ, is fluctuating to the touch, and when opened shows generally as its contents fluid blood.

Prof. R. Virchow, who compares it with the cephalæmatoma of new-born children, gives in his book on "Morbid Tumors," vol. i. p. 136, fig. 13, a very good representation of it.

Since 1833, when Dr. Bird of the insane asylum of Siegburg described this form of tumor, many cases of the kind have been observed in patients whose mental and physical energies were in a decreasing condition which would, sooner or later, reduce them to a state of idiocy.

In recent cases the ear is observed to be somewhat painful, reddened, and showing an increase of temperature; which inclined physicians to call this affection erysipelas of the ear. Soon after its appearance a kind of cyst containing blood is formed between the perichondrium and the cartilage. On close examination, small disks of cartilage are found clinging to the perichondrium, which have been detached from the cartilage of the ear.

The consideration of the origin of this tumor has led to great controversies, most authors regarding it as the result of external injuries inflicted by the nurses or by the patients themselves; which, however, cannot be considered as its cause, from the fact that patients affected with symptoms of excitement, living in the same asylum and in the same circumstances, never show this phenomenon. Though it has been stated that the Greek pancratists show in the still existing statues the same deformity of the ear which follows the absorption or evacuation of the blood, I never have observed in healthy persons similar symptoms, even after repeated injuries of the ear.

This subject has been written upon and discussed a great deal more than its practical importance would seem to demand; but, as all knowledge is useful, it seemed to me interesting to relate the explanation of Brown-Séquard, given in his recent lecture on diseases of the brain. According to this physiologist, the extravasation of the blood in the concha of the ear is caused by a lesion of the left posterior part of the brain, which may be produced in animals artificially by attacking this part of the brain. This will explain, in a reasonable and conclusive manner, a symptom whose real cause is so far unknown to us.

NOTES OF HOSPITAL PRACTICE.

PHILADELPHIA HOSPITAL.

MEDICAL CLINIC OF DR. H. C. WOOD.

Reported by Dr. W. H. Parrish, Resident Physician.

A CASE OF OBSCURE MALIGNANT FEVER.

H. H., æt. 42, a common laborer, and a native of Ireland, was admitted to the drunkards' ward September 27, 1872, in a state of intoxication and in a generally depressed condition. He had been drinking hard for some time, and had been an inmate of this ward on several previous occasions. After recovery from the immediate effects of his debauch, he complained only of pain and tenderness in the lumbar region, and was walking about. He was, however, pale and weak, though he slept well at night. He was cupped over the seat of pain, and placed under tonic treatment. There was no albumen in the urine, and it was free from blood.

On the evening of October 8 he had severe pain in both knees, with some dryness and heat of skin. That evening he was transferred to the medical ward, and received Dover's powder, gr. x.

October 9.—Rested well during previous night. Received cinchoniæ sulph., gr. xx. At 11 A.M., however, had a severe rigor, followed by high fever. At 7 P.M. his temperature was 107° F., but no delirium. Pain continued in knees and lumbar region. At night again received Dover's powder.

October 10.—A.M. Felt better than on previous evening. The fever was evidently lowered, though the temperature was not taken. Received cinchoniæ sulphatis, gr. xx.

P.M.—Had a rigor, though it was less severe than on the previous day. Evening temperature 106½° F. No delirium; Dover's powder again at night. For several days there has been some diarrhœa, amounting to three or four passages during the twenty-four hours, but no tympanitis.

October 11, 9 A.M.—Patient did not rest well during last night, though no delirium was present. Temperature now is 100⅕°. He looks pale, and the tongue is dry and brownish.

12 noon.—Dr. Wood saw him. Temperature 103⅘° F. There has been no rigor to-day, but the man is evidently worse; is more restless. The abdomen is somewhat tympanitic, and the bowels continue to be loose. There is no petechial or other eruption.

2.30 P.M.—Temperature 104⅕° F. Respirations 24, and laborious; though the lungs, on auscultation, seem clear, as do also the heart-sounds. Pulse 82. There are some muscular twitchings. Delirium present, but not very marked. Patient is inclined to lie in a semi-comatose condition, with low mutterings at times. The eyes are kept closed; pupils not contracted. The patient was now put in wet sheets wrung from water of the temperature of 37° F., and then well wrapped in blankets. When placed in wet sheets, he spoke of the cold, but no shiverings attended the process. In 20 minutes the temperature had fallen from 104⅕° F. to 103¾° F. The respirations remained at 24, and the pulse had fallen from 82 to 76. There was no perceptible change in the other symptoms.

At 2.50 P.M. the same process of packing in wet sheets was repeated; temperature of the water remaining the same. In half an hour the temperature of the patient was 102° F.; a fall in that time of 1⅘° F. There was less subsultus, and the delirium was somewhat diminished. The respirations were 18 per minute, and were less laborious. The pulse was 74. He was now taken from the wet sheets and placed between dry blankets.

At 9 P.M.—Temperature 104° F. Respirations 30. Pulse 100. At midnight, and on the 12th at 5 A.M., temperature, respiration, and pulse remained the same as at 9 P.M.

October 12, 9 A.M.—Seen by Dr. Wood. Has received, this morning, fifteen grains of quiniæ sulph. by the mouth. Temperature now 106° F. Respirations 50 and quite laborious. Pulse 132 and feeble. The man is delirious; is constantly talking to himself, but becomes aroused when spoken to. There is so much subsultus tendinum that the pulsations of the radial artery can scarcely be counted. He endeavors to protrude the tongue, but seems to want the ability. Quiniæ sulph. gr. v were now injected subcutaneously.

9.30 A.M.—Temperature 105½° F. Respirations 40 and very laborious. Pulse found to be 140, though counted with exceeding difficulty in the temporal artery. Subsultus and delirium very decided. Patient lies with eyelids open and eyeballs rolled upwards but not fixed; pupils dilated. He mutters wildly and indistinctly; jerks his arms about and clutches at imaginary objects; does not protrude the tongue, and seems not to appreciate anything spoken to him. This morning he passed his fæces and urine in bed unconsciously. Now enveloped in sheets wrung from water of 49° F.

9.50 A.M.—Seems more rational.

10 A.M.—Still in sheets. Temperature 104° F. Pulse 144. Respirations 34, and apparently less laborious. Tongue is protruded more readily; it is dry and brownish.

10.15 A.M.—Pulse 140. Respirations 44, and becoming more laborious; delirium again very decided. Can with difficulty be sufficiently aroused so as to protrude the tongue. His face is covered with drops of perspiration.

10.45 A.M.—Temperature 104° F.; other symptoms as at 10.15.

12.45 P.M.—Temperature 105° F. Respirations 40. Pulse counted with uncertainty, but made to be 106. Delirium and subsultus very decided. Trachea full of râles. He will, however, protrude the tongue when aroused.

1.30 P.M.—No change in general symptoms.

3 P.M.—Temperature 108°. Respiration 42. The pulse from its feebleness and the subsultus is uncertain, but made 110; no change in the other symptoms. Patient was now taken from the sheets used at 9.30 A.M., and placed in others taken from water of 50° F.

4 P.M.—Temperature 104° F. Respiration 56. Pulse too feeble to be counted.

4.20 P.M.—Patient died.

Autopsy, eighteen hours after death. Congestion of all the thoracic and abdominal viscera; spleen somewhat enlarged and friable; liver also softened; large, and a portion of small, intestines, congested, but Peyer's patches apparently normal. Brain not examined.

Dr. Wood, after narrating the above history and presenting the specimens to the class, remarked that the case was one of malignant fever, whose character was somewhat uncertain, yet probably was a pernicious malarial combined with a typhoid. It might be malignant typhus, but the chills militate against such a view. There is a form of fever, a pyrexia, occurring in rheumatism, which presents a somewhat similar character. In it the temperature suddenly rises to an intense degree, accompanied with delirium and all the symptoms of extreme adynamia. In this case, however, there were no decided evidences of rheumatism, although there was pain in the knees and back.

I have thought it would perhaps be well to remind you of the effects of heat upon the animal economy, and it was chiefly with the view of calling your attention to this subject that I have presented this case to you to-day. If you were to place an animal in a hot box, its temperature would rise to 108° or 110° F., and in the pigeon to 120° F. With this rise in temperature there would be all the symptoms of a high fever. Prostration, weakness amounting to paralysis, coma, and death, either with or without convulsions, would be the result. Should you remove the animal, when yet alive, from this box and place it in cold water, the temperature of the water would be seen to rise and that of the animal to be lowered. With this lowering of the temperature the animal would revive, and become restored to its normal condition, if the experiment had not been carried too far. If you have a man unconscious from sunstroke, with a temperature of 108° or 110° F., and with the application of cold water reduce that temperature, consciousness will often be restored. Bleeding in sunstroke will also reduce the temperature, but its employment must not be resorted to, as the loss of blood will lessen the chance of a final recovery.

The adynamia, subsultus tendinum, delirium, and other nervous symptoms of fever, are in great measure due to the effects of a high heat on the nervous centres. Moreover, in a high state of the animal temperature there is an increased oxidation, or in other words abnormally great waste of the tissues, while at the same time gland-action is diminished by the heat itself. The channels of exit for effete matter being thus choked at the very time that there is an increased pro-

duction of such material, there is a constant accumulation of poisonous matters in the system, and a consequent aggravation of the unfavorable symptoms. It must be borne in mind, however, that by reducing the temperature we do not effect a cure, we only abate the symptoms and diminish the chances of a fatal termination.

If the patient's temperature is not more than 102° F., never use the packing; but if the temperature is 104° F. or higher, life may depend upon its use. If above 103° F., do not be afraid to employ external cold and to advocate its value. The simplest method for general use is the application of the wet sheets. The water should be cold, its temperature approaching that of ice-water. Having wrung out the sheets, envelop the patient with them, and surround him with blankets. Repeat this process every twenty minutes, until the temperature is reduced below 103° F. If the wet sheets seem inadequate, resort to the cold bath; or, as some advocate, let the bath be tepid at first, and cold water be gradually added until the temperature is sufficiently reduced. The effects obtained from the latter method are not so pronounced, but are more permanent, than when the bath is cold from the first. In Germany the patient is sometimes placed upon ice-mattresses, made of rubber, and, when used, containing pounded ice. In this way the same effects are produced, but this plan is less applicable in private than in hospital practice. You will meet with no little opposition to the application of cold to the general surface in fevers, but you can appeal not only to common sense; you can point to such records as those of the German hospitals, in the late Franco-Prussian war, when the mortality of the continued fevers was reduced by a large percentage by this treatment.

The temperature-record of this case presents also another interesting feature. Five grains of the sulphate of quinia were given hypodermically, when the temperature was 106° F., and rising. In twenty minutes there was a reduction of one-half degree, affording an instance of the very general effect of quinia in fevers. Five grains of quinine injected under the skin are equal to about fifteen grains *per orem*. The hypodermic use of this drug must not be resorted to, however, unless there is some positive and unusual indication. An abscess with a sluggish ulcer is at all times to be apprehended. If there is not a thorough solution of the drug, a few points of crystals will be left in the tissues, insoluble or nearly so, by the fluids in contact with them, thus remaining as permanent irritants. The preparation used in this house consists of water, one ounce; quin. sulph., one drachm; and tartaric acid enough to dissolve the salt; the solution to be *passed through filtering-paper*. I am not certain that tartaric acid is better than some other acids. The acid, however, whether one or the other, is not what gives rise to the local trouble. With proper precaution in the use of the preparation named, abscesses will be rare.

(To be continued.)

Caffeine (*Lancet*, Oct. 12).—In a recent number of *Pflüger's Archiv* Dr. Aubert describes some researches on this substance. Seeking to ascertain the proportion of cafeine or theine in a cup of coffee or tea, he arrived at numerical results somewhat above those of his predecessors. According to him, a cup of coffee, forming an infusion of 16.75 gr. of dry coffee-grains, contains about 0.1 gr. to 0.12 gr. of cafeine; and an infusion of 5 gr. to 6 gr. of dry leaves of very good tea contains about 0.1 gr. to 0.12 gr. of cafeine.

He studied the effect of this alkaloid on the nerves, muscles, respiratory movements, heart, and circulation. Cafeine increases the reflex excitability, and may produce tetanus. Dr. Aubert, with most authors, considers this a medullary tetanus; for it is not produced in the leg of a frog if the ischiatic nerves are cut, and it takes place in a limb the circulation in which has been stopped by a ligature before the subcutaneous injection of the cafeine into the skin of the back. An injection of 0.005 gr. into the skin of a frog, 1.20 gr. into the jugular of a rabbit, 0.200 gr. into the jugular of a dog or cat, produces tetanus. Dr. Aubert did not observe the weakening of excitability of the nerves referred to by Voit and others. According to him, the nervous excitability is altered only in the case of the nerve being plunged directly into a solution of cafeine. The muscular excitability is not affected so long as the cafeine is not applied to the muscles themselves.

Confirming Uspensky's experiments, Dr. Aubert shows that the production of apnœa by means of artificial respiration (?) counteracts the development of the convulsions produced by cafeine,—a phenomenon similar to that which Rosenthal was the first to apply in cases of strychnic tetanus, and which appears to be applicable to all tetanus produced by reflex influence. As to the dose necessary to kill an animal apnœised, they were various; 3 gr. of cafeine did not kill a dog of 10 kilos. in which artificial respiration was produced. Other dogs in the same conditions succumbed to an injection of 0.25 gr. of cafeine. Cafeine at first produces an increase in frequency of the pulse, but a diminution of its bulk takes place very quickly (one minute after the injection), and sometimes determines the immediate death of the heart. Small doses, 0.1 gr. to 0.15 gr., injected into the skin, produce no effect on the heart of a rabbit, while a dose of 0.25 gr. causes an acceleration of the heart and the respiratory movements. The increased rapidity in the heart-beats and the rise of arterial pressure observed may be attributed, Dr. Aubert thinks, to a paralysis, more or less complete, of the nerves proceeding from the ganglia to the muscles of the heart and an excitation of the arresting apparatus of the heart. He does not agree with those who say it is cafeine which gives to coffee its principal qualities. He thinks the reviving action of coffee, which makes it such a favorite beverage, is not yet scientifically explained.

Rupture of the Urinary Bladder.—Dr. Erskine Mason, in the *New York Medical Journal* for August, 1872, gives an account of a case of rupture of the urinary bladder in a man twenty-six years of age, in whom, general peritonitis being imminent, the bladder was laid open through the perineum, as in the lateral operation for stone. This was done nearly forty-eight hours after the accident (a fall down a long flight of steps), and on the thirty-seventh day he was discharged cured.

Dr. M. refers to the literature of the subject, quoting Dr. Stephen Smith's paper in the *New York Journal of Medicine* for 1851, as the best ever written upon it. In this there are tabulated seventy-eight cases, with only five recoveries. Mr. Birkett, in Holmes's "System of Surgery," quotes the records of fifty cases, all but three of which resulted fatally.

Four modes of operative interference are mentioned: 1. Opening the bladder above the pubis, as in the high operation for stone, or else simply tapping the organ in this locality; 2. Tapping the cavity of the pelvis either above the pubis, or the pelvic cul-de-sac through the rectum; 3. Perineal section, and then dilating the membranous portion of the urethra and neck of the bladder, as in the median operation for stone; 4. Opening the bladder either by the lateral or bilateral method, as in lithotomy.

The last-named is the method advocated by Dr. Mason, and successfully resorted to by him in the case he reports. He gives the credit of proposing it to Dr. W. J. Walker, of Boston.

PHILADELPHIA
MEDICAL TIMES.
A WEEKLY JOURNAL OF
MEDICAL AND SURGICAL SCIENCE.

The Philadelphia Medical Times is an independent journal, devoted to no ends or interests whatever but those common to all who cultivate the science of medicine. Its columns are open to all those who wish to express their views on any subject coming within its legitimate sphere.

We invite contributions, reports of cases, notes and queries, medical news, and whatever may tend to increase the value of our pages.

All communications must bear the name of the sender (whether the name is to be published or not), and should be addressed to Editor Philadelphia Medical Times, care of the Publishers.

PUBLISHED EVERY SATURDAY BY
J. B. LIPPINCOTT & CO.,
715 and 717 Market St., Philadelphia, and 25 Bond St., New York.

SATURDAY, NOVEMBER 16, 1872.

EDITORIAL.

WHAT IS HOMŒOPATHY?

ACCORDING to the census of 1870, unless our information is wholly incorrect, the proportion of homœopathic practitioners was a fraction over seven per cent. of the whole body of the medical profession in the United States. Be it remembered that this is after over thirty years of effort to propagate the doctrines of that peculiar school, and in spite of a strong tendency on the part of physicians everywhere to investigate, and to adopt if satisfactory, whatever new principle or practice promises to aid them in the battle with disease. Can it be, then, anything but the warmest enthusiasm that enables an orator before the New York State Homœopathic Medical Society to say, "Who will deny that, at no distant date, either under the name of the Homœopathic School, or adopting a title now often used synonymously,—that of the 'Modern School of Rational and Liberal Medicine,'—we may see the two great branches of the medical profession, for many years estranged and often hostile, united in one solid phalanx, under the ample folds of that banner, unfurled to the gaze of an astonished world by the genius of Samuel Hahnemann, on which inscribed in letters of living light are the words '*similia similibus curantur*,' and, actuated by that philosophic and Christian motto, *in certis unitas, in dubiis libertas, in omnibus charitas*,' marching onwards to the attainment of conquests over disease and death, such as have never yet been depicted in the dreams of the most ardent medical enthusiast? Then will have come the millennium of medicine. God grant a consummation so devoutly to be wished!"

No doubt the homœopathists would be glad to have the profession at large adopt their absurd dogma, to which they themselves, in their practice, do not adhere. No doubt they would be glad to have us, with all the results of scientific research, and the records of past battles gallantly won or as gallantly lost, come over to their ranks. But why do they not show us one single case in which a remedy produces, in the healthy body, the genuine symptoms of a disease in which it is known to be useful? Why do they not show us that belladonna will induce something more than the most superficial and unimportant phenomena of scarlet fever? that chloral or the bromide of potassium will prevent sleep? that mercury or iodide of potassium will give rise to the essential secondary or tertiary manifestations of syphilis? How do they explain the perversity with which the entire scientific world declines to recognize them? We cannot suppose that Humboldt, Arago, Sir Humphry Davy, Agassiz, and a host of others, dead and living,—men of inquiring minds, intolerant of any bar to the freest examination of every theory or hypothesis in regard to the secrets of nature,—would have hesitated for one moment to give in their allegiance to any doctrine, if it could maintain itself by facts.

From our own free wanderings in the field of homœopathic literature, we are convinced that the more extensively regular physicians are acquainted with it, the more strengthened will they be in their sense of its absurdity. Even the advocates of that dogma find that their own school affords them insufficient nutriment; for in a recent number of one of their leading journals, out of thirty quoted items, *twenty-five* were from regular medical sources, *three* only from homœopathic; one was from a secular paper, and one was not credited at all.

We answer the question which heads this article, by asserting that homœopathy is a mere name, signifying nothing.

PREMATURE INTERMENTS.

OF all the horrors which have a fearful fascination for the human mind, perhaps that of being buried alive is the most wide-spread. And when the vast number of yearly interments is considered, it would at first sight seem as if, according to the doctrine of chances, some few persons, at least, must be consigned to the grave before the extinction of life. Every one knows of the precautions taken in

some burial-places to insure the detection of the slightest sign of returning animation; every one does not know how fruitless these have been.

The fact is, however, that in almost every instance where there is the least room for doubt, the idea must suggest itself to some one concerned. Upon no other point is certainty so feverishly sought for, so dreaded, and yet so insisted upon. Except when circumstances demand speedy burial, as in times of pestilence, this certainty is always attainable; and it is in such exceptional cases, we believe, that all the alleged detections of premature interments are said to have happened.

One fact has singularly escaped notice; and that is that, should a living person be buried, the fatal event must take place not only quickly, but easily. Under no circumstances can life be maintained without respiration; and the carbonized air enclosed within the narrow space of a coffin would in itself be a narcotic which would prevent any return of consciousness.

THE HORSE-INFLUENZA.

OUR readers will have had such a surfeit of items in the daily papers with regard to the influenza now prevailing among animals of the horse kind, that we propose only to call attention to a few of its more remarkable features.

In the first place, the singular rapidity of its progress precludes the idea of its spread by contagion. It was first known in Canada, less than six weeks ago, and since that time has spread over the whole of New York, and the Eastern States, and Pennsylvania, and is now (November 9) felt in Baltimore. Only if very large numbers of horses were moving in this southward direction would the theory of its propagation in this way be at all tenable. Then, again, it has affected all the horses, in small villages and in the country. Some atmospheric convection, independent of wind-currents, must necessarily be the means of its spread.

Secondly, the universality of the disease is to be noted: we may perhaps say that not a single horse has escaped, as even those which have not been actually laid up have shown the effects of its depressing influence. Mules seem less susceptible to it than horses, but many of them, and we believe all more or less, have felt it. Within the memory of the oldest horsemen there has never been such a visitation; and indeed the peculiar inconveniences entailed are such as would have impressed the recollection of an epizootic of the kind upon the minds of the public as well.

Thirdly, the exemption of all but animals of the horse kind. There have, it is true, been a few cases of influenza in the human species, but the health of the city may be said to be exceptionally good, and the mortality returns are very small. The vague rumors of horned cattle being affected, which have prevailed from time to time, are not confirmed so far.

The deaths seem to have been limited to such horses as were previously in poor condition, from age, over-work, or disease; some also, from neglect in the early stages of the epizootic, have been attacked with fatal pneumonia. It may be that, like the poison of scarlatina or smallpox, the peculiar cause of this disorder is in some cases so virulent as to hurry off the animals affected before the symptoms are fully developed; but of this the evidence is not yet satisfactory. Another cause of death has doubtless been the working of horses before they had fully recovered their strength, congestion of the lungs being especially apt to occur under such circumstances, and to run on into fatal pneumonia.

We trust that from the intelligent and careful investigation of this remarkable scourge, there may be derived some facts bearing upon the natural history and mode of propagation of the zymotic diseases which affect the human family.

LEADING ARTICLES.

"HONOR TO WHOM HONOR IS DUE."

UNDER the above caption, the *Nashville Journal of Medicine and Surgery* (Sept. 1872) finds fault with us for quoting, from *The Practitioner* of June last, a statement by Mr. Poland, made in the Guy's Hospital Reports, in regard to the treatment of subclavian aneurism by ligation of the innominate artery, without reference to the sole successful case, that of Dr. Smythe of New Orleans. We certainly should have called attention to so brilliant a triumph of surgery by one of our own countrymen; and it was solely by inadvertence that the omission occurred. It gives us pleasure now to quote the account of the operation as given in the *Nashville Journal* for October; merely premising that not only Erichsen and Gross, but Ashhurst, Hamilton, and Sir William Fergusson (with some trifling inaccuracies, in his "System of Practical Surgery," ed. of 1870), speak of the case:

"The account of this singularly successful operation was published by Dr. Smythe in the *New Orleans Medical Record*, it having been performed on the 15th of May, 1864, in the Charity Hospital of that city; the

operator was assisted by Drs. D. L. Rogers, of New Rochelle, New York (not by Dr. J. Kearney Rodgers, of New York City, now deceased), Holliday, Boyer, Bacon, and Orton. Ligatures were applied to the innominate and right carotid arteries. Fourteen days afterwards a hemorrhage occurred to syncope, but was arrested in two days by lint and compression with a weight. Small shot were next poured into the wound, and the ligature to the brachio-cephalic artery pulled away. On the 17th of June, thirty-three days after the operation, about half of the shot were picked out, when the bleeding recurred. July 5, he had a terrific hemorrhage, and the patient again fainted. July 8, fifty-four days after the first operation, the vertebral artery was tied. The circulation in the right arm now became very feeble, so that the brachial artery appeared occluded, and the limb œdematous, but in a few days these unpleasant symptoms subsided. The ligature to the vertebral came away on the tenth day after it was applied, when the patient gradually improved, and was pronounced well the 15th of September, four months from the date of the operation upon the brachio-cephalic and right carotid arteries, being the first and only successful application of a ligature to the innominate.

"The operator, in this case, deduces the important lesson that whereas, in twenty recorded instances, ligature to the innominate, or subclavian artery in its first portion, *without that of the vertebral*, has proved fatal, it is reasonable to suppose that it would always do so."

THE RECENT ALLEGED DEATH FROM ETHER.

IN the last issue of this journal (Nov. 9, p. 93) we quoted at large the report given in the *New York Medical Journal*, of a case in which death was ascribed to the administration of ether. We had intended to analyze this record, but have been anticipated by Dr. H. J. Bigelow, a portion of whose remarks on the subject we quote from the *Boston Medical and Surgical Journal* of October 24:

"For ourselves, if called upon to indicate, in the absence of complete evidence, the probable cause of this death, we should perhaps rearrange the statement somewhat as follows:

"A man of nearly seventy years, reduced by a fracture near the trochanter, of eighteen days' standing, and by pneumonia, was subjected to a somewhat protracted inhalation before coming under the influence of ether. At the end of ten or twelve minutes his breathing became so feeble and irregular that etherization was suspended and artificial respiration was resorted to. In the course of four or five minutes more, there being some muscular action, the respiration being also stronger, and the pulse better, the ether was again administered, but the same bad symptoms soon supervened. On examination, the pupils were now found to be dilated. The heart was still beating (although there was probably no pulse at the wrist), but attempts at resuscitation were this time ineffectual.

"Such an account would better accord with previous experience. The vitality of a patient enfeebled by age and disease proves to be easily depressed, and, after giving to the operator good and sufficient warning of his enfeebled condition, he succumbs; an occurrence which may serve as a fresh and salutary lesson to the surgeon to exercise care during anæsthesia by ether, and still more by chloroform, of a system thus depressed; but an accident we believe to be impossible to ether, with the pulse held and the respiration attended to.

"On the other hand, we repeat, no precaution yet devised by human ingenuity will prevent the insidious shock of chloroform, in even a small dose, from occasionally and abruptly killing a healthy subject. This is the peculiar and usual *death from chloroform;* and of its approach neither pulse nor breathing gives indication."

REVIEWS AND BOOK NOTICES.

ON THE TREATMENT OF DISEASES OF THE SKIN, WITH AN ANALYSIS OF ELEVEN THOUSAND CONSECUTIVE CASES. By Dr. McCALL ANDERSON, Physician to the Dispensary for Skin-Diseases, and to the Cutaneous Wards of the University Hospital, etc. etc., Glasgow. Crown 8vo, pp. 180. London, Macmillan & Co., 1872.

The book before us consists of two distinct parts: the first, devoted to an analysis of eleven thousand consecutive cases of skin-disease; the second part, in no way connected with the first, to the therapeutics of diseases of the skin. Ten thousand of these cases were met with in hospital practice, while the other thousand came under observation in private. The first part of the book, the analysis of the cases, appeared about one year ago in the columns of the *Lancet*, but the chapters on therapeutics, if we are correct, are new to the profession.

The analysis of this vast number of cases is extremely interesting, especially when compared with diseases of the skin as they occur in our own country, for it will be noticed at once how prevalent some of these affections are in Scotland, and how rare they are in America. For example, out of the ten thousand hospital cases there were two thousand five hundred and twenty-seven cases of scabies and as many as one hundred and fifty-six cases of tinea favosa; large numbers when compared with the statistics of our own hospitals and dispensaries. Did space permit, we should take pleasure in speaking of the work more at length, for it is a little volume which if read cannot fail to leave a most favorable impression. The chapters are written in an easy, readable style, and the cases are described with great accuracy and vividness, contrasting most pleasantly with many descriptions of these diseases which we are compelled to read. The second part of the work, on therapeutics, is particularly valuable, giving as it does merely the writer's *own* experience, and not the experience of others minus the author's, as is too apt to be the case with writers of the present day. One has in these few chapters on therapeutics the experience of one of the fore-

most of modern dermatologists, given in a simple, straightforward manner, comprehensible to all. The volume is not a text-book, but reads like a series of short essays, concisely worded.

THE PHYSIOLOGY OF MAN. By AUSTIN FLINT, JR., M.D. Vol. iv. The Nervous System. New York, 1872.

However much we may regret that so able an investigator as Dr. Flint should be kept from original research by any other form of labor, no one can fail to see in his text-book how good a thing it is sometimes to have a review of this special science by one so gifted as an experimentalist. In fact, no one but a biologist familiar with laboratory-work could have written just the kind of volume before us, and the criticism made by one worker on the work of another is far more apt to be shrewd as well as charitable than if it is to be done by closet-scholars. The day, we trust, is over when any chair of physiology in our great schools can be filled by men who never made an original research and whose lessons must lack that vigor and freshness which comes only of having practically learned what they profess to teach. The laboratory should be to the professor of physiology what the hospital clinics are to the professor of practice. And what applies to the oral teacher fits equally well the case of the maker of text-books. He will teach best and write best who has learned his lessons from the great book of nature; and just such qualification Dr. Flint brings to his task. The result is a volume on the most difficult part of physiology, so clear, so well arranged, so concise and so interesting, that it is the book of books, both for the student and the doctor. If it errs at all, it is in the direction of too great brevity; a pardonable error nowadays. On the other hand, as models of terse physiological teaching and honest criticism, we may point to the chapters on the cranial nerves and to that on the basal ganglia of the encephalon. The latter is remarkable for the decisive refusal to concede points unproven by research, and for the frankness of admission as to our defects of knowledge.

One of the best-written chapters in the volume is that on the cerebellum, but we doubt sincerely as to whether its conclusions will be received by most biologists as correct. Indeed, had the author treated the subject with the severe logic which marks the portion last mentioned, we think he could hardly have reached the belief that the cerebellum is the organ of co-ordination of muscular acts.

The style of the book is distinct and simple; no sentence needs to be read twice because of any obscurity of statement. As to the engravings, there had better have been many more, or none.

TWENTY-NINTH ANNUAL REPORT OF THE MANAGERS OF THE (NEW YORK) STATE LUNATIC ASYLUM FOR THE YEAR 1871. Transmitted to the Legislature March 6, 1872. 8vo, pp. 87. Albany, 1872.

This report is a valuable contribution to the literature of insanity. Besides the regular formal report of the asylum at Utica, it contains accounts of twenty-seven fatal cases, in fifteen of which post-mortem examinations were made. An interesting outline of the action of the State of New York in regard to the care of the insane for the past twenty years is also given.

BOOKS AND PAMPHLETS RECEIVED.

Report on the Structure of the White Blood-Corpuscle. (Extract from the Transactions of the American Medical Association.) By Joseph G. Richardson, M.D. Philadelphia, 1872.

The Physician's Visiting List for 1873. Philadelphia, Lindsay & Blakiston.

Modern Medicine: a Lecture delivered October 7, 1872, Introductory to the Course at the Jefferson Medical College. By J. M. Da Costa, M.D., Professor of the Theory and Practice of Medicine. 8vo, pp. 38. Philadelphia, J. B. Lippincott & Co., 1872.

GLEANINGS FROM OUR EXCHANGES.

REPORT OF A CASE OF CÆSAREAN SECTION (*Lancet*, Oct. 12, 1872). By G. E. Yarrow, M.D., L.R.C.P. Lond., Medical Officer to City-Road Workhouse, etc.—On Sunday, September 15, I was summoned by a midwife attached to the City of London Lying-in Hospital, to see Maria N——, on whom she had been in attendance upwards of twenty-four hours.

On my arrival at the house, at 1.30 P.M., I learned the following particulars: The patient was thirty-four years of age, and had been married two years and a half. This was her second pregnancy, she having aborted on the previous occasion at the third month. She was the subject of rickets, had a lateral curvature of the spine in the lower dorsal region, and a curve forwards in the lumbar region. The midwife informed me that the liquor amnii had escaped at 2 P.M. the previous day, since which time there had been little progress in the labor, and the pains were ceasing.

Upon examination *per vaginam* I found that the head of the child was pressing upon the promontory of the sacrum, and could not enter the pelvis, the antero-posterior diameter of which was about one inch and a half. I saw the impossibility of relieving the patient by craniotomy. Choice, therefore, had to be made between cephalotripsy and Cæsarean section. Under these circumstances, I sought the counsel of Dr. Burchell, the surgeon-accoucheur to the hospital. Upon examining the patient, he was of opinion that Cæsarean section would give the best chance to mother and child, in which I fully concurred.

In consequence of the poverty of the patient, and her not having had proper nourishment for several days, I suggested her removal to the workhouse infirmary, which was gladly acceded to by the patient and her friends.

At 4 P.M., all being in readiness, Dr. Aubery (Dr. Burchell's assistant) administered chloroform, and the patient was soon under its influence. Dr. Burchell, well supplied with hot wet flannels, stood on the left side of the patient, I, standing on her right, made an incision about five inches in length, slightly to the right of the linea alba, dividing the skin, fat, and rectus muscle. I then divided the two layers of peritoneum on a director. The question of the position of the placenta then occurred to me, but I could not feel any pulsation by placing my hand on the uterus; and Dr. Burchell urged me to go on with the incision through the uterine wall; this I did, and, strange to say, cut immediately upon the placenta, which was evidenced by a gush of blood. To complicate matters, an arm came through the incision. I at once enlarged the opening, pushed back the arm, removed the placenta, and, seizing the legs, withdrew the child, who gave evidence of vitality, and was removed by a nurse during the latter stage of the operation. Dr. Burchell held the edges of the uterine wound closely in contact with the edges of the external wound. No intestine was seen, but a piece of omentum came down, and was pushed up out of the way. The uterus now began to contract, and Dr. Aubery drew the edges of the external wound together by inter-

rupted suture, over which lint and strapping were placed, and over all a broad flannel bandage. The patient was then left undisturbed for two hours, during which time she took some brandy and water and beef-tea.

I saw her at 6 P.M., and superintended her removal from the labor-bed. She expressed herself as feeling comfortable. 9 P.M., has taken small quantities of brandy-and-water, beef-tea, and ice. Pulse 120.

The patient after this presented the symptoms of a low form of peritonitis, and died at 12.45 P.M., on the 20th, nearly five days from the time of the operation.

Autopsy.—4 P.M.: Body badly nourished; measured only four feet two inches. The thighs were bent forwards, and legs outwards. Between the sutures the wound was gaping. The uterine wound measured one inch and a half; was open and smelt very offensive; there was a small quantity of dark-colored blood in the pelvis. The intestines and their peritoneal covering were healthy, but that investing the posterior portion of the pelvis was inflamed. With the husband's permission I have possession of the pelvis, which I propose adding to the collection of the Obstetrical Society.

The infant, a female, is progressing very satisfactorily, and has been taken from the workhouse by the father.

The *British Medical Journal* of October 19 says that this operation was recently performed in a case of extra-uterine fœtation, at the Hospital for Women (London), with a fatal result.

History of Anæsthetics (Dr. G. Vivian Poore, *Lancet*, October 12, 1872).—A few words on the history of anæsthetics will not, I think, be unprofitable. To us whose medical recollections do not extend very far it is a matter of wonder that capital operations could be performed at all in what may be called the pre-anæsthetic period. A few years back I met a middle-aged sailor whose thigh had been amputated in the Black Sea, during the Crimean war, without chloroform. I inquired of him if the pain were not something very awful; but he assured me that in his case the suffering was not very intense, "for you see, sir," he said, "they gave me the best part of a bottle of rum before they began, and I didn't find much of it." In point of fact, they first made him drunk, and then operated. There is no doubt that before the introduction of chloroform it was very commonly the custom to give various narcotics and stimulants before submitting patients to the knife. Dioscorides, a writer on materia medica who lived A.D. 50, says that "decoction of mandragora is to be given to those who require to be cut or cauterized, when, being thrown into a deep sleep, they do not feel any pain." This may be regarded as the first mention of anæsthetics, and there is abundant proof that between A.D. 50 and 1846, this rough and imperfect form of anæsthetisation was frequently had recourse to. About the year 1798 Sir Humphry Davy discovered the anæsthetic properties of nitrous oxide; and in 1844, Dr. Horace Wells, of Hartford, Conn., U.S., had a tooth removed without pain whilst under its influence. In 1818 an article appeared in the *Quarterly Journal of Science and Arts* in which the resemblance between the effects of the vapor of ether and nitrous oxide is pointed out. In September, 1846, Dr. Morton, of Boston, U.S., drew a tooth while the patient was under the influence of ether vapor; and in the following month Dr. Warren, of Boston, removed a large and very vascular tumor from the lower jaw, the patient being anæsthetized. Anæsthetization had its origin in Boston, U.S.

In December, 1846, ether was first used in this country by Mr. Robinson, a dentist of Gower Street, who first administered the ether and then pulled the tooth. The first operation of magnitude which was performed under ether in this country was an amputation of the thigh by Liston in the theatre of University College Hospital, on December 21, 1846. I have had a description of what took place from an eye-witness. Liston informed the students that they were going to try a "Yankee dodge for making a man insensible to pain, and that Mr. Squire, the chemist, was going to administer ether." While the etherization was progressing, Liston stood in a semi-impatient and incredulous way, balancing his knife and playing with its point. At last came the signal "He is ready, sir," and in another instant almost the thigh was off, the patient not taking the least notice of the operation. Liston was astonished, as well he might be, and summed up his opinion of etherization in these words, "Good God! why, it's better than mesmerism!"

In 1847, Jacob Bell and Sir William Lawrence used chloric ether; and in November of the same year, Sir James Simpson, at the suggestion of Mr. Waldie, of Liverpool, was led to try chloroform as an anæsthetic, and with what result you all know.

On the Use of Baths in Acute Rheumatism, attended with Head-Symptoms and High Temperature. By Dr. Henry Thompson, of the Middlesex Hospital (*British Medical Journal*, August 3, 1872).—A case has lately occurred in the Middlesex Hospital illustrating the beneficial effects of the bath in acute rheumatism, attended with head-symptoms and high temperature. Dr. Thompson, in his remarks on the case, observes that it is only now and then, in a few rare and scattered instances, that acute rheumatism proves fatal by an unexpected outbreak of overpowering nerve-symptoms, and such a result would have ensued in the instance recorded, according to Dr. Thompson's opinion, if the bath had not been used. The fatal issue in similar cases was formerly referred to the occurrence of metastasis, meningitis, and the like, but now it is said to be due to hyperpyrexia. To this last term, if used in a practical sense, Dr. Thompson makes no objection, as the importance of very high temperature cannot be overrated as a symptom; but in a pathological point of view he thinks that its influence has been exaggerated, for the nerve-symptoms invariably precede the hyperpyrexia. Nevertheless a high body-heat, ranging from 108.6 degrees to 112, is incompatible with life, and it is necessary to lower it by such means as are available, and Dr. Thompson thinks that the use of the bath is the best therapeutical agent. The temperature of the bath is 90 to 95 degrees in the first instance, and is gradually reduced by the addition of cold water to 70 degrees. The clinical thermometer must be practically the best guide for the employment of the bath, for at a lower body-temperature than 102.5 degrees it would not be desirable to use it. It is important to observe that, in the case recorded by Dr. Thompson, the most severe and extensive chest-complications, such as pneumonia, pleurisy, bronchitis, and pericarditis, underwent no perceptible change for the worse in consequence of the bath. The case itself is recorded at length, with the thermometrical observations taken at frequent intervals from day to day, and the effects produced by the baths, which were eight in number, are accurately noted. The case, however, although terminating in recovery, was a tedious one, and the convalescence was exceedingly slow.

Carbazotate of Ammonia to Supersede Sulphate of Quinine (*Ib.*).—In a recent communication to the Société de Thérapeutique de Paris, Dr. Dujardin-Beaumetz investigated the character, properties, and uses of carbazotate of ammonia (combination of ammonia with carbazotic, picric, or trinitrophenic acid), especially as a therapeutic successor to sulphate of quinine. After relating the successful employment of this salt in inter-

mittent fever by Braconnot, Calvert, Aspland, Bell, Chazereau des Thureaux, Manopa, etc., Dr. Beaumetz gave the results of six cases treated by himself, and of various experiments carried on upon animals and man. Like quinine, carbazotate of ammonia diminishes the strength of the pulse, and brings on heaviness, cephalalgia, and even delirium, and is eliminated by the kidneys. These effects have again been stated by Dr. Beaumetz. As to the clinical results they may be summed up thus:—Case 1: Quotidian ague; recovery after four days' treatment; daily dose from one to two centigrammes of the substance in pills. Case 2: Quotidian ague (sulphate of quinine having been given without effect); complete recovery after five days; five pills used. Case 3: Tertian ague; recovery after eight days; two pills a day. Case 4: Quotidian ague; recovery after eight days. Case 5: Facial neuralgia; speedy recovery. Case 6: Tertian ague; sulphate of quinine had been administered during seventeen days with no result; completely cured after the administration of six centigrammes (about one grain) of the salt for two days.

Dr. Beaumetz draws the following conclusions from the various facts observed in his six cases or brought out by his experiments: Carbazotate of ammonia is very efficacious in intermittent fever; the suppression of the paroxysms may be obtained by the use of two to four centigrammes (one-third to two-thirds of a grain) daily; given in these doses the drug has never had any bad effects, and seems to be better tolerated than sulphate of quinine; the physiological action of the substance closely resembles that of sulphate of quinine.

Dengue (*Madras Monthly Journal of Medical Science*, May 1872).—Surgeon Sparrow, of the 89th Regiment, gives an account of the dengue fever as observed in Cannanore, among officers and troops who had just arrived from Aden, where dengue was prevailing. Isolation proved successful in preventing the extension of the disease. A general uniformity of symptoms characterized all the cases. There was a sudden invasion of the disease by pain of the limbs, followed by the hot stage of fever, intense frontal headache, furred tongue, acute pain of the joints (the most marked symptoms during the progress of the disease), the pain so severe in some cases that the patient was seen to fall to the ground as though paralyzed; the stage of pyrexia lasted three days, when, with the exception of continued pain in the joints, all the symptoms were relieved; there was a clean tongue, normal pulse, cool and moist skin. On the fifth day a burning pain of the palms of the hands was complained of; on examination they were found to be swollen and covered with red-colored blotches. The eruption then extended up the arms, and in most cases the entire body became covered with the erythematous eruption, resembling that of scarlatina; fever returned and lasted twenty-four hours; after which there was a gradual abatement of the symptoms, but soreness of the feet and swelling of the hands, with inability to close them, continued. In many the pains in the joints continued at intervals for a month. No delirium attended any of the cases. Except in one or two cases where there was slight diarrhœa, there were no sequelæ; relapses, consisting of increase of articular pain, with slight return of fever, were observed in three or four.

Aspiration in Hydrocephalus (*Deutsch. Archiv für Klin. Med.*, July 26, 1872).—Dr. Buttenwieser communicated a case of hydrocephalus in a boy of 26 weeks of age treated by aspiration with the syringe of Bergsen. The circumference of the head measured 54 ctm. The deformity of the head was very marked (*tête carrée*). The needle was entered to the left of the median line at a point of greatest prominence. The body of the syringe filled at once, and was emptied into a glass through the side tube. After the removal of about ¼ ℔, both sides of the head had collapsed considerably and the needle was withdrawn. The whole operation was performed without accident. The child cried throughout, and became pale towards its close.

Chemical examination of the fluid showed water 98.34, albumen 0.33, organic matter 0.41, ash 0.82. The organic matter consisted of fat, cholesterine, and traces of urea. The ash was chiefly composed of common salt and phosphate of soda.

The wound was closed with plaster. For a few days there was no change in the child's condition, but the fluid had reaccumulated in 24 hours to its former amount. Compression with plaster bandages was now undertaken. The child became worse, the fluid continued to accumulate with all the symptoms usual to compression, and death occurred in eleven days after the operation.

Hydatid Cysts passed by the Rectum.—Dr. C. C. Sherard, of Mobile, Ala. (*Med. and Surg. Reporter*, Aug. 17, 1872), records a case in which a woman, aged twenty-nine, after nearly two weeks of pelvic trouble, with supposed retroversion of the womb, the replacement of which was twice attempted, suddenly expelled *per rectum* "a large quantity" of hydatid cysts; the discharges continuing for five days. An attack of peritonitis then declared itself, and lasted some days. On the 21st, another series of evacuations of hydatid cysts began, and lasted thirty-six hours. After this she had a thrush-like exudation in the mouth and fauces, and then a severe "pelvic cellulitis" with abscess. The "ulcer in the bowel, where the hydatids had passed through," was discovered by Drs. Gaines, Gilmore, and Sherard, by rectal exploration. During the night of May 2, about a quart of very fetid watery liquid gushed from the vagina, and this flow continued all day. May 5, "she passed a lump from the rectum about the size of a hen's egg, which she says looked like a piece of boiled gristle; from her description of it I was induced," says Dr. S., "to believe it was the base of the hydatids." Recovery was complete by the 10th of May.

Sciatic Hernia.—Dr. Marzolo of Padua has related the case of a woman who first came under notice in 1847, at the age of 30. Ten years previously she had observed a small swelling in the left buttock; it disappeared when she lay down, but reappeared in the erect position and gradually increased. She had had four abortions, and borne one healthy child. When seen, the hernia extended over a part of the buttock, as far as the trochanter, and forward to the groin. The abdominal wall was retracted. On lying down or sitting, the greater part of the contents of the swelling could be returned into the abdomen; defecation and coition were difficult. Last year the patient again came under observation. Her condition had changed but little; but the hernia was now irreducible, and at the lower part there were dulness on percussion and fluctuation. A puncture was made, and nine litres of fluid removed. Diarrhœa set in, and the patient soon died. No post-mortem examination could be obtained.

Chloride of Potassium in Epilepsy (*Echo Méd. et Pharm. Belge*).—Dr. Lander advocates this salt as better than bromide of potassium in epilepsy. He finds it is more active, costs five-sixths less, and has not the inconvenience of the secondary effects of bromide of potassium. He begins with small doses, and has continued the use of the drug for several months without any bad consequences, in daily doses of from 3 grammes 50, to 5 grammes 50 (1 to 2 drachms). Moreover, Dr. Lander thinks that the bromide is converted into a chloride in the stomach, so he suggests the immediate use of the chloride.

Enormous Brain in a Boy.—The *British Medical Journal* of October 19 says, "A boy thirteen years of age died in the Middlesex Hospital, a few days since, from injuries caused by a fall from an omnibus. His brain after death was found to be very large, and to weigh fifty-eight ounces,—about eight ounces above the weight of the average male adult brain. He had been a particularly healthy lad, without any evidence of rachitis, and very intelligent."

MISCELLANY.

The *Lancet* of October 12 says, "The success of the British Association for the Advancement of Science has stimulated our neighbors across the channel to imitate its constitution and proceedings; and the late meeting at Bordeaux may be regarded as representing the complete formation of the corresponding Association in France. Already upwards of 700 members have enrolled themselves on its books, and its capital amounts to 137,000 francs, or to between £5000 and £6000. M. Combes was originally nominated President, but died almost as soon as the Society was formed. M. Claude Bernard was then chosen, and is the present and practically the first President. He too, however, was unfortunately prevented by indisposition from making an inaugural address, and the duty devolved upon M. de Quatrefages. In the course of this, after referring to the disasters of the country, he observed that in these days the greatness of a State is not measured alone by the extent of its territory or the number of its inhabitants, and competition does not take place alone on the field of battle. "Now more than ever the domain of intelligence, the platform of science, have also their battles, their victories, and their laurels. The scientific worker is also a soldier, and can experience the excitement of strife and the intoxication of success; but, more fortunate than the soldier, he has no general above him who can carry off the honor that should belong to another. However small may be his merit, he at least receives all the credit due to him. The successful worker, moreover, not only experiences the pleasure of gratified self-love, but he may feel also with patriotic ardor that his work reflects honor upon his country. . . I have recently assisted at similar meetings," says M. de Quatrefages, "in Belgium, Italy, and Denmark,—the first, in the calm of her neutrality; the second, in the midst of her efforts to possess a new future; and the third, in grief and sorrow,—and find that they all obtain in the double love of science and of country stimulants or consolations unknown to ambitious egotism. At Brussels, in the celebration of the hundredth anniversary of the Academy, it was said, 'Belgium is but little in the political world, but it has enlarged that of the intellect, and shall do so still more.' At Bologna, in presence of the splendors of an extinct civilization, they said, 'We will resuscitate it.' At Copenhagen they said, 'Denmark may perhaps disappear from the map; we will make it live again in our works.' France, too, has its bleeding wounds and material mutilation; to men of science it remains to bring noble compensation for its evils."

The sections into which the Association has been divided are nearly the same as those of the English Association,—comprising mathematics and astronomy, navigation and the military art, physics, chemistry, meteorology and physical geography, geology and mineralogy, botany, zoology, anthropology, medicine, agronomy, geography, economy, and statistics.

At this the first meeting several general addresses were read: one by M. Laussedat, on the services that modern science can render the military art; a second by M. Le Fort, on reform of French military surgery. The papers read appear to have been both numerous and interesting. They include one by M. Dupuy, on animal heat; one by M. Bitot, on the use of veratria in cardio-vascular affections; and others on lympho-sarcoma, on the recovery of sensibility and motor-power after section of nerves, on a new mode of termination of nerves, and on the physical contractility of the non-living animal tissues, by MM. Trélat, Rubio, Bouillaud, and others.

We can only wish the Association God-speed, and hope it will advance with steps as rapid as those of the British Association.

Quadruple Amputation.—In the autumn of 1869, Dr. Begg, of Dundee, amputated the whole of the extremities in the case of a young woman named Robertson, whose hands and feet had assumed a gangrenous condition, the proximate cause of which was considered to be embolism. After the operation, a subscription was raised, and the poor woman sent to London, where, at the request of some influential friends of hers, Mr. Heather Bigg constructed for her some especially devised prothetic appliances, in which the distinguishing features were, that the artificial hands were automatic in action, opening and shutting their fingers at the will of the patient. This peculiar prehensility gave her the power of grasping even so small a substance as a crochet-needle, and enabled her to gain a comparatively lucrative livelihood by making shawls, etc. So admirably did she do this, that one was sent by her to the Queen, who, struck by the excellence of the workmanship and the remarkable means by which it was accomplished, generously gave the poor woman £5. The artificial legs were also so arranged as to enable her to stand and walk with the aid of crutches. Three years have passed since she first began the use of extraneous appliances, and she now writes an admirable hand, besides knitting, feeding and dressing herself, etc. "In a communication made by her a few days since, which is now before us," says the *British Medical Journal*, "she writes that she can walk alone quite easily with the aid of crutches, and that no one can observe the cause of her lameness. The case is one of no common interest, owing to its being the only one on record in which the whole of the four extremities have been removed. Apart from its pathological value, as indicating how

life may be saved by judicious interference in cases of embolic gangrene, there remains the gratifying result that, by the use of ingenious mechanism, the patient is enabled to gain her living, whilst presenting nearly the same external appearance as if she still retained possession of her natural limbs. It is a unique case, and a triumphant instance of mechanical ingenuity."

A Reliable Test of Death.—In 1870 a prize of twenty thousand francs was offered by the Academy of Sciences of Paris for the discovery of some positive sign of death, one which can be applied at any time by non-medical persons, requiring no apparatus, and unmistakable in its indications.

Of course a number have been proposed. The latest, and so far the best, is that suggested by Dr. Hugo Magnus, of Breslau, in *Virchow's Archiv* for August 19, 1872. It is simple, physiological, and conclusive, being based on the fact that when the circulation positively ceases the man is dead. No matter how profound the coma or trance, no matter how death-like the lethargy, some circulation *must* continue, be it ever so sluggishly. Once it has stopped, resuscitation is impossible.

All that one has to do, therefore, is *to tie a string firmly around the finger of the supposed corpse.* If there is the least spark of life left, that is, if the blood circulates at all, the whole finger, from the string to the tip, will gradually turn a bluish red, from the engorgement of the veins. Nothing else, no post-mortem infiltration, can be mistaken for this appearance.

The *Medical and Surgical Reporter* justly attributes great importance to this suggestion, and considers it the most practical and satisfactory yet made.

Medical Reform in France.—*Le Mouvement Médical* says that it is announced that the Government will submit, at the next session of the Chamber of Deputies, the scheme of a law looking to the establishment of several Faculties of medicine in France. It is contemplated to greatly enlarge both the buildings and the means of instruction of the schools at Paris and Montpellier; and new schools will subsequently be created at Nancy, Lyons, Bordeaux, Nantes, Lille, and Toulouse. The Faculty at Nancy will be specially charged with the duty of following the improvements made (*les progrès accomplis*) in the German universities, and communicating them to the other Faculties in France. The latter will be more particularly devoted to the training of medical practitioners.

The writer remarks, "If the Government really entertains the designs ascribed to it, we should be glad to know how the sentinel-faculty at Nancy is to instruct the rest, and what the professors of these other schools will have to do if they are not to keep themselves *au courant* with the work going on in all countries."

Inoculation of Smallpox by Skin-Grafting (*Brit. Med. Jour.*).— In a recent discussion on skin-grafting in the Berlin Medical Society, Herren Hahn and Zülzer referred to an instance recorded in the *Deutsche Militair-ärztlich. Zeitschrift,* in which portions of skin for grafting were taken from the amputated limb of a woman in whom, the day after the operation, the eruption of smallpox appeared and proved fatal. One of the four patients on whom the skin was grafted had smallpox in a mild form. He was, however, a man of intemperate habits, and died, according to Herr Zülzer, of pneumonia.

A Medico-Legal Case (*Lyon Médical,* September 1, 1872).—A female at full term of pregnancy died of cholera in Vienna. The physician in attendance was arrested for not having performed the Cæsarean section *post-mortem.* The college of physicians of the Vienna faculty, being interrogated as experts, declared that the physician did not arrive until one hour after the death of the woman, and that the fœtus does not survive the death of its mother more than five or six minutes. Besides, the annals of science show that in cases of cholera, the death of the fœtus always precedes the death of the mother. The physician was accordingly discharged.

Prince Bismarck, says the Vienna correspondent of *Le Mouvement Médical* (Oct. 4), has proposed the foundation of an imperial institution to deal with all questions concerning public health. Among the medical authorities consulted in regard to it are mentioned Warrentrapp of Frankfort, Reclam of Leipsic, and Hirsch of Berlin. The law carrying out this idea was to be speedily submitted for consideration by the Council of the Confederation.

The same writer notes the death of Prof. Ebert, director of the clinic for children's diseases at the Charité Hospital in Berlin. His place will probably be taken by Dr. Henoch.

Worcester City Hospital.—By the fortunate termination of a will case, the city of Worcester becomes possessed of about $100,000, to be held in trust for the establishment of a free hospital. The property was left to the city by Deacon I. Washburn, as a memorial of his two deceased daughters. The city also holds in trust a large bequest (nearly $500,000) from the late George Jaques, for the same purpose. It is proposed to unite the two bequests, for the more satisfactory accomplishment of the object.

Donations to Hospitals.—The National Orthopædic Hospital (London), the Infirmary for Epilepsy and Palsy (London), and the East London Hospital for Children, have each received donations of £1000, anonymously. The latter is the fourth gift of the same amount received by that institution from the same source.

A useful form of disinfectant has been recently brought into use in England, namely, sawdust soaked in a saturated solution of carbolic acid. It is convenient for many purposes, cheap, easily prepared, and not liable to be swallowed accidentally, as ordinary liquid disinfectants are.

Dr. C. B. Brigham, of Boston, was, on the 8th of August last, decorated by the Emperor of Germany

with the Imperial Order of the Crown, for his valuable and meritorious services rendered alike to wounded German and French soldiers in the hospital at Nancy in the recent war.

The Lyons Medical Congress.—A French correspondent writes to the *British Medical Journal*, under date of the 27th September, "You have announced the programme of the Medical Congress of Lyons, and we have realized it. I know not how to figure to you the events of this Congress, so as to give you a lively image of what has passed. After taking part in your English meeting of the British Medical Association, I see here something so different that it afflicts me to describe it to you. Want of order, want of brevity, want of arrangement, want of practical common sense,—an egotism which sacrifices one's multitudinous surroundings to one's personality,—the desire to appear wise, the love of long-sounding phrases, want of conscience and of severe introspection,—that is how the work of my own compatriots now shows itself to me when I come to it fresh from the emotions awakened by your grand, quiet, well-ordered, unostentatious British Medical Association. We have no sections, no limit of speech, no sifting committees; the whole Congress must assist at the apotheosis of each man's vanity; and hours pass themselves in diffuse, wordy, and I-would-be-eloquent orations, which have commonly been only the warmed-up dishes that have graced more than once the banquets of our French societies, and for which now a provincial celebrity is sought. This is considered improving the occasion. Each orator, as he descends from the tribune which he has occupied for half an hour or an hour, asks his friends and himself, not 'What have I taught? How have I advanced the objects of the Association?' but 'Have I made a brilliant improvisation?' 'Was my speech full of *entrain*, or erudition?' Twelve mortal sittings did we endure, with gradually thinning audiences. The result has been, I fear, a death-blow to French congresses,—platitudes, verbosity, egotism, dulness, but not one addition to our knowledge. Looking through the notes of all the sittings, I cannot find one paper really worth transcription; but, with the help of the official *procès-verbal*, I may be able to pick out enough of abstracts to fill a page or two which will not be wholly novel, and will preserve in your pages some sort of record of the fourth annual congress in the first year of the revenge of our beloved France. Alas! it is not thus that we shall rise above the level of our too pressing neighbors, or teach them to keep their place."

Blockading Cholera.—In the *Gazette Médicale d'Orient*, we have an editorial article, as well as the report of a speech of M. Pardo, before the Imperial Society of Medicine at Constantinople, denouncing in powerful terms the evils brought on by an attempt to blockade an epidemic of cholera within the quarter of Kassym-Pacha, by placing guards around it, who were ordered to bar all egress. This was done by a commission of seven medical men,—one of whom, however, resigned on seeing the results. These are described as most deplorable. No increased cleanliness, no fresh supplies of water—so much needed in Constantinople—were given; terror spread through the unfortunate quarter, which contained a population of 25,000, and the sick were in many cases allowed to die unattended. The inhabitants, deprived in many cases of their means of subsistence, were allowed twopence per head daily. Some managed to corrupt the guards; others forced their way through with arms in their hands. The quarantine, of course, failed; but the neighboring quarter of Haas-Keny was included in the blockade, and with the same unsuccessful results. According to the *Gazette Médicale d'Orient*, from the 2d of October to the 12th of December, 1871, there were, by official returns, 2914 deaths from cholera, a mortality of 62 per cent. on those seized. The writer in the *Gazette Médicale* thinks this much underrated. He and M. Pardo, instead of despotic measures of quarantine which have always failed, advocate a plentiful supply of fresh water, increased cleanliness, and recommendations addressed to the people to practise temperance and proper hygienic precautions. The population of Constantinople is stated to be about a million, most of whom live in complete negligence of hygienic laws.

The Medical Profession in Boston.—From the recently issued Medical Register of Boston and its vicinity, we learn that the number of physicians, members of the Massachusetts Medical Society, residing in and about Boston, is three hundred and thirty-nine.

Mortality of Philadelphia.—The interments reported at the Health Office for the week ending Nov. 9, 1872, were 225; of which 7 were of bodies brought from the country; making the mortality in the city 218; of the whole number, 122 were of adults, and 103 of minors. Among the causes of death were:

Consumption of the Lungs	38
Other Diseases of the Respiratory Organs	37
Diseases of the Circulatory Apparatus	12
Diseases of the Brain and Nervous System	31
Diseases of the Digestive Apparatus	14
Zymotic Diseases (2 from Smallpox)	13
Typhoid Fever	5
Cholera Infantum	3
Casualties	9
Debility (including "Inanition" and "Marasmus")	13
Still-born	6
Old Age	7

The meteorological record kept at the Pennsylvania Hospital was as follows:

	Thermometer. Max.	Min.	Barometer. (2 P.M.)
Nov. 2	52.5°	45.0°	30.13 in.
" 3	49.0	45.0	30.10 in. (Rain.)
" 4	52.5	41.5	30.38 in.
" 5	55.0	39.5	30.45 in.
" 6	55.0	49.0	30.30 in. (Rain.)
" 7	53.0	50.0	29.78 in. (Clearing.)
" 8	50.5	44.0	29.95 in.
" 9	53.0	38.0	30.16 in.

SATURDAY, NOVEMBER 23, 1872.

ORIGINAL LECTURES.

CLINICAL LECTURE

ON CERTAIN PAINFUL AFFECTIONS OF THE FEET.

BY S. WEIR MITCHELL, M.D.,

Physician to the Orthopædic Hospital and Infirmary for Nervous Diseases.

THERE is another form of pedal pain, which is fortunately most rare, and which, so far as I am aware, has been nowhere competently described. It is, however, a malady of considerable interest; to the patient because it is a grave disqualification for all active pursuits, and to the doctor on account of the obscurity of its origin and of the obstinacy with which it resists all forms of treatment. One case of this very unusual disorder has presented itself among the hundreds of instances of neural disease which have claimed our aid in the last two years. This alone would justify me in speaking of it as uncommon, and I may add that I have seen in all five cases, and that a friend has lately given me the notes of a sixth. It so chances that the first example has been thus far unmatched in severity among those that I have since seen treated. In place, therefore, of taking our hospital case as my text, I shall briefly describe the graver instance, which, perhaps from the fact of its intensity, so impressed the matter on my mind as to cause me to study curiously every case which has since fallen in my way.

The patient, a sailor, aged about forty, while in the U.S. naval service on the coast of Africa, suffered from sunstroke. This was followed after a few months by a grave attack of coast-fever, and from this seemed to date an enfeebled condition of the heart, with an apex-murmur heard in the systole. He reached the Norfolk Hospital eight months after his fever, and was there during the whole winter. Some time early in the next year he began to have dull, heavy pains, at first in the left, and soon after in the right foot; the pain was a dull ache, and seemed to be in the interior of the foot, between the sole and the instep. At first, and indeed for three months, the pain was unaccompanied by swelling, but in April this new symptom was observed, after much exercise, and then only.

The disease progressed rapidly, and when I saw the man, in June, his condition was no less strange than pitiable. He was a well-made, vigorous person, of rather ruddy complexion. His appetite and digestion were good, his bowels regular, and his urine, save some slight though constant deposit of urates, in all respects normal. He told me that he had pain in the feet whenever he attempted to walk, but that while at rest in bed he was perfectly comfortable. The case, as he spoke of it, was to me so novel that I somewhat mistrusted his statement, and therefore directed him to walk up and down the ward and about the grounds until I sent for him, which I did when at the close of an hour my visit was over. He made his appearance in the ward, walking with the step of a man whose feet are tender. On examining his extremities I found them both swollen. They scarcely pitted on pressure, but were purple with congestion; the veins were everywhere singularly enlarged, and the arteries were throbbing visibly. The whole foot was said to be aching and burning, but above the ankles there was neither swelling, pain, nor flushing. On other occasions I examined him in bed, and then caused him to stand for a time. Almost at once, without previous pallor, the feet began to fill with blood, and after a quarter of an hour or less, if he walked, the pain appeared, and with it the swelling so increased as after a time to force him to lie down. He was very sure that he had suffered pain long before either swelling or redness was observed, and I am disposed to think this statement correct. As the autumn came on and the weather grew cold, I was able to verify another of his statements, to the effect that cold relieved him and that heat increased his sufferings. In fact, he preferred to wear slippers without stockings, and while on cool days he could walk for an hour before his pain became great, in warm weather a few minutes of exertion were enough to bring about this result. A hot foot-bath had a like effect, and cold bathing was almost the sole means of speedy relief. A long series of therapeutic experiments failed to afford him any permanent ease. The local use of cold, and of alternate heat and cold, bandages, sedative washes, lead-water and laudanum, leeching and blisters, digitalis, arsenic, and tonics, all alike failed to help him, so that at last, having gained something from the cold of early winter, he left us, and I have never heard of the issue of his most singular history.

Some years passed by before I met with a second case, and of it I have only a general knowledge and no special notes. The patient, a healthy young man, but subject at times to long and severe attacks of palpitation of the heart, while working in an iron foundry, and therefore constantly on foot, began to have, towards the evening of each day, pain and ache, as he called it, in the feet. By-and-by it came earlier in the day, and at last attacked him whenever he was an hour or two on his feet. Occasionally, after great exertion, the feet flushed a little, but did not swell. In this, as in the sailor's case, summer was the time of the greatest torment, and a cool day gave more or less relief. After a time the pain became so severe that he was forced to seek a sedentary occupation, after which the pain, on the whole, became less, although ready to appear anew whenever he took too much exercise on foot. I should add that, although some years have now gone by, this tendency still continues, while in no other way does the patient show any manner of disease.

My next case came to me from Dr. James King, of Pittsburg. The patient, aged twenty-one, managed, at the time I saw him, a large printing-office. He was healthy up to 1864, when, after an extended

army-service, he had ague, which clung to him a long while. Returning home, much weakened in health, he began for the first time in his life to have, after long walks or after standing for a time, vague pains in both feet. Disregarding these, he continued to be much on his feet, and engaged in a business which taxed severely all his powers; and soon his annoyance increased so much as to cause him to seek for aid.

When I saw him in 1868, he was suffering most gravely. Usually he arose in the morning free from pain, but it came on in one or two hours, and increased in severity so long as he remained active and on foot. It thus happened that by nightfall both feet were aching and so painful as to make further exertion impossible. The seat of pain was not distinctly fixed, being rather, as he said, throughout the feet. There was never at any time swelling, but once or twice a month some great excess of movement would cause the feet to be darkly flushed and congested. At times also, as in the evening or whenever unusual or sudden exercise had been taken, the pain was of a burning character, and the feet throbbed. At such times they became tender, and were so sore that pressure or the effort to pull on a boot caused extreme pain.

The patient was free from heart-disease or other troubles, functional or organic, and, like the previous case, had not had gout or rheumatism.

As in the other cases, the summer brought more intense pain, and it was in hot weather easily induced by the slightest exertion; while winter brought not only a general relief, but also enabled him to walk much longer without producing pain. Having learned these facts very early, he saved himself suffering as much as possible by wearing the lightest of foot-coverings. Later in his case the pain was chiefly on the sides of the feet, and at all times he could obtain perfect relief or insure freedom from annoyance by rest in the recumbent position. In October, 1868, Dr. C. B. King, of Pittsburg, writes to me that he has carefully watched the patient while applying electricity, and that he has never seen the feet either red or swollen. He adds that the right foot is the worst of the two, and that the severest pain is in the centre of the sole. He could find no tender points when the patient had been for a while without exercise, as in the mornings; and when the feet were the worst the tenderness varied in position, and was usually general and not acute or in limited localities; neither was it seated in the muscular tissues of the feet, an observation which I myself confirmed on several occasions.

In June, 1871, I saw the next instance of this obstinate disorder. Mr. C., æt. thirty-seven; married. A healthy, well-built man, free from any constitutional taint, and never having had gout or rheumatism. When nineteen years of age, Mr. C. lived on a farm and worked as a field-hand to learn the business. After a few months, and in midsummer, he began to feel in the feet a sense of weariness,—a fatigued, sore feeling, as if he had walked too long. As this grew worse it came to last over night, and was then eased by walking in the morning. At last the soles became so sore that he would sometimes crawl down-stairs in the morning on his knees, and after cooling his feet with pump-water would pull on his boots. There was neither redness nor swelling, and the soles were the chief seat of pain, which was a dull, heavy ache, always much under the control of temperature, heat increasing and cold relieving it. The autumn and winter brought entire ease.

He quitted the business of farming, and became a clerk. During nine years he walked a good deal, and felt each summer some slight return of annoyance, but the winter brought absolute relief. When twenty-nine years old, a change of business brought with it heavier responsibilities and a great increase of exercise on foot.

The first warm weather in May caused a return of the foot-trouble, from which, up to this time, nine years, he has not been altogether without discomfort at any time.

The pain and suffering in his first attack were unlike those of the other cases whose histories I have related to you, but when they returned they differed little from these. The heat of summer and too much foot-covering increased the pain and the readiness with which exercise caused it, while cold had exactly a reverse influence.

After walking for a time, he felt as if there was a cushion under the toes and the ball of the foot. Then the foot burned and pricked, and these latter feelings, which were so sharp at times as to amount to stinging, became worse for a little while when resting after a walk. His mode of relief was to bare his feet and place them on a higher level than the remainder of his body. At no time was there redness or swelling, and only once or twice could I find spots of tenderness on the sides of the feet, which, I should add, were well formed.

Dr. Keen has kindly given me notes of a case which in no essential respect differs from those already described. The patient, however, was a seamstress, and hers is the only example I know of which has been noted in a woman. In addition to these cases I have met with two others of like nature but less persistent.

Before discussing this very interesting affection, it is well to say that we meet with in practice soreness of the soles due to gout, and more rarely to rheumatism, but this trouble is clinically very unlike that which we are now considering. Of it I find nowhere any full description,—in fact, in but one place any description at all. More may have been written, but it has not fallen under my notice. Prof. Gross has, at p. 977, vol. ii. of his "Surgery," half a page devoted to "Pododynia." This, he says, is so common among tailors that it ought to be called after them. Unaccustomed to walk, the erect posture brings on *pain and tenderness* which are deep-seated and are always made worse by pressure and by walking and standing. There is little swelling, and seldom discoloration. Dr. Gross thinks this is probably a form of inflammation situated in the periosteum and plantar aponeurosis, attended with determination of blood and effusion.

Few physicians, we suspect, would, on such evi-

dence, admit the proof of inflammation to be sufficient; but it seems altogether probable that the cases which Dr. Gross describes are of close kindred to those which I have narrated. It will be well to group the symptoms together, and see what main features the natural history of this affection offers.

A man previously well or not, as may chance, begins to feel excessive fatigue of his feet after long walks; then it comes after short walks, and in bad cases after standing, or perhaps even a few minutes afoot brings it on. Nearly always it arises first in summer; and, throughout, cold helps and warmth hurts it. Once begun, it soon becomes pain, and the grade of pain may be high or low,—mere aching or absolute torment; but, severe or not, rest cures it; and rest with coolness and elevation is more grateful than anything else.

This alone is an indication that the symptoms are related to an increase in the amount of blood in the part. More direct evidence is to be had from the first case quoted, and in less degree from the others. The feet swell or they do not, they flush or not, as the case is severe or slight; but if they redden and swell, it is because of exercise, and rest speedily banishes both symptoms. The sense of ache and pain is followed by vaso-motor palsy and by the nutritive phenomenon of œdema, but this is only in extreme cases, and usually the pain exists alone. Mr. Paget has reported lately a strange case in which exercise caused basal spasm, and the subsequent rest brought about extreme basal relaxation, pallor during movement, flush after it.

In my cases there was no precedent paleness, and the reddening was seen only in the worst instances, or in extreme states of the mild ones. My own patients resembled Mr. Paget's only in the one sad particularity of being incurable. For two of them it were almost easier to say what had not been done, than what had been done.

In the sailor's case, after many expedients had failed, I put him in bed for a month, but had the annoyance to see the malady return the first time he stood erect. Equally vain was it in all cases to try to overcome the evil by steady exercise. I have tried blisters, which Dr. Gross found useful, douches, bandages, faradic and galvanic electricity, and, of course, drugs, until I was in despair. The treatment reduced itself to a minimum of exercise, to keeping the feet cool, and to securing in summer the coldest climate attainable.

Fortunately, this distressing disorder seems to be uncommon; but there may be other physicians who have met with cases of it. I should be glad to learn whether or not my brethren have found it as obstinate a foe as I have done.

CARBOLIC ACID AND SNAKES.—*The Medical Times and Gazette* of August 31, in a notice of Dr. Fayrer's work on "Indian Venomous Snakes," quotes the statement that these reptiles have the greatest repugnance to carbolic acid, which is a powerful and fatal poison to them. It is therefore of the greatest use in keeping them out of houses.

Practical use may be made of this fact, if it extends to other animals of the snake kind, as it probably does.

ORIGINAL COMMUNICATIONS.

ON THE EFFECTS OF THE BROMIDES IN EPILEPSY, WITH SPECIAL REFERENCE TO THE BROMIDE OF POTASSIUM.

BY M. GONZALES ECHEVERRIA, M.D.,

Resident Physician to the New York City Asylum for the Insane, Ward's Island, N.Y.; Consulting Physician to the New York Hospital for Epileptics and Paralytics, etc. etc.

THE essential relations of epilepsy to heredity, to the habits of life, or to organic derangement in its broader sense, are as numerous as they are complex, rendering in their varied influence the treatment and management of epileptics exceedingly difficult. My experience with a large number of these cases, for a period of over twelve years, has strongly impressed me with the fact that, in the desire which is usually manifested to try every new anti-epileptic remedy, or to discover the real one, there is not sufficient thought given to the bearing of pathogenic circumstances on which no kind of specifics may exert any appreciable influence. This is obviously proved by the frequency with which the simplest cases of epilepsy turn out to be the most hopeless and unyielding to extolled anti-epileptic mixtures, so long as these latter are used indiscriminately, and the treatment generally not based on sound and well-established principles, both of therapeutics and pathology. I have arrived at the conclusion, upon the researches of others as well as my own, that the vaso-motor or sympathetic system is primarily affected, and that cerebral anæmia is the initial phenomenon in epilepsy. Several agents, therefore, should be capable of counteracting the original causes of the morbid condition here in question, and it would be interesting to ascertain their comparative efficacy. The anti-epileptic virtues of conium have been the subject of researches published in this journal by myself and Dr. A. E. Macdonald, and I propose now to state the results of more extensive experiments with the most popular anti-epileptic, namely, bromide of potassium, and its therapeutical value in epilepsy as compared with some of its kindred salts.

I have followed closely the effects of the bromide of potassium, in periods varying from seventeen months to eight years, with 486 epileptics: 227 males and 259 females. I satisfied myself, on repeated and modified trials, that the salt proved powerless in 104 cases: 58 males and 46 females. I am not prepared to speculate upon the real causes of so inefficient an action of the bromide, nor could I detect any etiological or symptomatic resemblance between these epileptics. Digitalis, hyoscyamus, belladonna, iodide of potassium, and iodide of mercury, diminished the frequency and severity of their fits, and consequently their mental deterioration, without, however, radically affecting the disease. Among the males, two exhibited a hereditary taint of nervous disease; six were epileptic since their infancy; two had syphilitic epilepsy and died thereof; three were in a far-advanced stage of dementia when placed under the bromide, and six of the remain-

ing cases had epileptic insanity, superinduced in two instances upon a traumatic injury to the head. Hereditary tendency to epilepsy existed in five females; five others had had fits since their infancy; and lastly, of the remaining females, twenty-six were insane and two demented.

Not one of the epileptics has taken less than twenty grains of bromide of potassium three times a day, or for shorter periods than seventeen weeks. I prescribed the salt, at first with tincture of columbo or of sumbul, but for the last four years chiefly with the succus conii, or the fluid extract of conium. I have constantly associated the arseniate of potash with the bromide, since I discovered, seven years ago, that by their combination we avoid the eruption usually induced by the bromide of potassium, or mitigate it, and because, undoubtedly, arsenic exerts besides a tonic beneficial effect upon the patient. I have not recognized any marked advantage from the admixture of the bromide of ammonium, or the carbonate of soda, which rather increases the disagreeable taste of the bromide solution.

The formula of the anti-epileptic mixture I have ordinarily prescribed is:

℞ Potassii bromidi, ℥iv—℥vj;
Liquor. potassæ arsenitis, f℥j;
Succi conii, f℥ij—f℥iv;
Aquæ dest., ad f℥vj.

Misce. Sig.—One tablespoonful three times a day, or oftener as required by the case.

Ordinarily, as stated, the smallest dose of bromide of potassium prescribed to my patients has been twenty grains three times a day, given to them shortly before meals, and the last dose at bedtime. This quantity has never been augmented unless the condition of the patient indicated an approaching paroxysm, or the frequency or violence of the attacks demanded it. The largest dose of bromide of potassium taken by hospital patients has been seventy-five grains three times a day, continued in two females during a period of from fifty to seventy days without the supervention of bromism, and with unmistakable arrest of the fits. Another girl, at the hospital for epileptics, took for twenty-one days three drachms and a half of bromide of potassium daily, with great improvement, and no signs of bromism. These, however, are exceptional instances, since I have seldom seen forty grains of bromide repeated thrice daily for four or five days without causing bromism.

The average dose required in obstinate cases of epilepsy has been thirty grains of bromide of potassium; and no difference has been remarked in its effects upon the diurnal and the nocturnal attacks.

The epileptic fits have disappeared under the uninterrupted administration of the bromide of potassium in the following patients, for the length of time respectively specified, to wit:

1 male,	2	females;	total	3,	for	8	years.
3 males,	2	"	"	5,	"	6	"
6 "	8	"	"	14,	"	5	"
5 "	12	"	"	17,	"	3	"
31 "	37	"	"	68,	"	2	"
3 "	2	"	"	5;	had one fit in 3 years.		

In the foregoing cases the attacks occurred from one to twenty-two times a week, and in one female, who has continued for five years free from fits, they recurred as many as seventy-six times in one week. Six males and eight females had *petit mal* and *grand mal;* eighteen males and twenty-six females had both diurnal and nocturnal attacks. In one of the males, who has been for three years without fits, I trephined the skull and removed an exostosis of the internal table of the occipital; the fits recurred twice within a week after the operation, and the patient was subsequently kept under bromide of potassium (℥ij to ℥j thrice daily) and ergotine, no epileptic attacks having returned thereafter.

The respective ages of the above patients were—males: 22 adults, 16 adolescents, 11 children; females: 28 adults, 21 adolescents, 15 children.

The cause of the disease was:

Intemperance,	18 males,	12 females.
Dentition,	1 male,	2 "
Amenorrhœa,		6 "
Fright,	2 males,	1 female.
Scarlatina,	1 male,	1 "
Mental overwork,	1 "	
Injury to the head,	1 "	

The origin of the disease could not be positively ascertained in the other cases. One of the females had an older sister, who was an inmate of a lunatic asylum, was discharged cured therefrom, and continued in a sound condition of mind until her death, eleven years after. She had no knowledge of hereditary insanity in her family, but her maternal grandmother was affected with chorea. The father of one of the male children had been intemperate before the child's birth, and subsequently died from paralysis and delirium tremens. Intemperance was again acknowledged in three more cases: twice in the father; one male and one female adolescent; and one in the mother of a female, also adolescent.

The phenomena attending the exhibition of the bromide of potassium to epileptics are of two kinds: those usually observed in almost every case, and those of less constant, or exceptional, occurrence. The first includes slowness of the pulse and increased temperature of the skin; fetidity of the breath; hypersecretion from the salivary glands and kidneys; eruption on the skin; anæsthesia of the skin, pharynx, and mucous membranes; congestion of the conjunctiva and retina. Among the less frequent phenomena I have noticed diarrhœa, nausea, vomiting, diplopia, ataxia, and mania, or aphasia.

One of the immediate effects of the bromide of potassium on epilepsy is to decrease the frequency of the pulse peculiar to the disease, rendering it, in addition, more firm. The temperature of the skin increases also by one or even two degrees, and the respiratory movements, which so strongly contrast in their slowness with the rapidity of the pulse, become more frequent and in a more natural relation to the latter. I may further assert, incidentally, that, throughout the progress of epilepsy, the evening temperature of the skin is always higher than the morning; a fact which exhibits itself always

more conspicuously before the approach of a fit, and may enable us to predict it.

I have repeatedly observed this rise in temperature, which has been likewise noticed by Dr. Julius Mickle, of the Derby County Asylum, in relation to the epileptiform and congestive seizures attending the general paralysis of the insane (*Journal of Mental Science*, April, 1872).

The fetidity of the breath is a phenomenon of rather transient duration, generally disappearing on a continuance of the bromide of potassium, and superinduced by this latter in a more remarkable degree than by any of its kindred salts. This fetidity occurs earlier and more conspicuously in individuals who do not attend to regular cleanliness of their teeth; hence its most striking occurrence among hospital patients. The phenomenon does not acknowledge as its sole cause the elimination of the salt through the salivary glands, for I have on several occasions ascertained by chemical test the presence of bromine in the saliva, without any foulness of the breath. In no instance, however, have I met with the latter without more or less swelling of the pharynx and tongue, which leads me to assume that the main source of foulness proceeds from decomposition of the detached epithelial cells. The secretion of a thick mucus, and a parching of the patient's throat in the morning, are hardly ever absent. A. Voisin, upon the observation of seven cases, states that the elimination of the bromide of potassium takes place through the salivary glands during the winter only; but when the salt has been given in thirty or forty grain doses I have never failed to detect the presence of bromine in the saliva irrespective of any seasonal influence. I may further remark that the hypersecretion of the salivary glands has been preceded by a dryness of the mouth and throat, and at times also by trouble in deglutition.

The renal secretion is generally increased, and I am satisfied, upon careful examinations carried out at the Hospital for Epileptics, that the quantity of urea in the urine is notably lessened by the bromide of potassium, a fact which has been already noticed by other experimenters. The elimination of the bromide through the kidneys takes place immediately upon its administration, and persists for several days after its discontinuance.

Dr. A. E. Macdonald, late Assistant Physician to the Hospital for Epileptics, has detected evidences of bromine in the urine of epileptics secreted ten or twelve days after they had ceased using the bromide of potassium, a fact equally established by the researches of Namias. I have also been able to observe the accumulation of bromine in other organs besides the kidneys, for its unequivocal existence was demonstrated in the cerebral tissue of an epileptic who died at the hospital seven days after he had stopped taking bromide of potassium. The elimination of the bromide appeared more active in the urine secreted after meals or any prolonged exercise, and it has been more abundant in winter than in summer. Diuresis, again, has generally seemed more pronounced with adult males and children than with female adults.

Concerning the anaphrodisiac properties of the bromide of potassium, I have seen many cases of satyriasis in epilepsy, and there are at present several at this asylum on whom the salt has been unsuccessfully tried. The failure has not been exclusively in epileptics, but in the insane generally. I have carried the bromide of potassium to its highest limits—two and a half drachms in six hours—in a female nymphomaniac and paraplegic, without further effects than those of bromism.

One of the epileptics at this asylum, immediately upon the convulsive paroxysm, falls into a state of epileptic insanity and masturbates himself furiously, without the least attention to those surrounding him. He has taken, during such paroxysms of insanity, as many as two drachms of bromide of potassium in three hours, after being kept on the use of ninety grains of bromide daily. His most violent attack of satyriasis broke out while he was in a condition of bromism which I had induced, expecting thereby to avert the fits. Furthermore, I have had to discontinue the bromide of potassium at night, as it induced lascivious dreams with seminal emissions in an epileptic who had never had them before. Similar phenomena have been observed by Voisin, who met with partial satyriasis, nocturnal erections, lascivious dreams, and great seminal loss, superinduced by the bromide of potassium. Rabuteau states (*Gazette Médicale*, 1869, p. 395) that of two strong dogs to whom he had given ten grammes (one hundred and fifty grains) of bromide of potassium, one did not pay any attention to a slut in heat, whereas the other would not let her rest; whereupon Rabuteau concludes that the anaphrodisiac effects of the bromide are as manifest with the dog as with the man. Rabuteau, however, should have experimented, before arriving at this conclusion, upon other substances not reputed anaphrodisiac, but capable of keeping the action of the nervous system in abeyance, to ascertain if they also would not have operated on the dog as did the ten grammes of bromide of potassium. I have seen fifteen grains of hydrate of chloral, injected in solution on the right thigh of a lively slut in heat, render her completely indifferent to the dog for more than twelve hours that she remained under the influence of chloral. Thirty drops of Magendie's solution, injected in the same manner, induced identical results. Shall we conclude therefrom that morphia and chloral possess any real anaphrodisiac properties? I have moreover noticed nocturnal erotism with voluptuous dreams, as just cited after the use of the bromide of potassium, produced in another epileptic by belladonna or atropine; whereas I may no less positively assert that the prolonged administration of narcotics or hypnotics has frequently determined a more or less complete loss of sexual desire among several of my nervous or insane patients. The same effects attend the abuse of alcoholics. I do not believe that the inward morbid feeling prompting self-pollution in epilepsy, or in any other form of insanity, originates solely from the genital organs any more than does our normal sensual satisfaction. I have seen maniacs in restraint gratifying their erotic desires in the strangest manner; while it is

beyond question that voluptuous sensations are not exclusively located in any particular organ of the body, but awakened and carried to their utmost degree by thoughts, without the necessary intervention of the genitals. Moreau de Tours cites the case of a girl, a nymphomaniac, in whom no means could repress the satisfaction of her venery, since her gratification could be complete even when she did not bodily lend herself to it. For all these reasons, therefore, I should consider the assumption of anaphrodisiac properties in the bromide of potassium as unwarranted, as well as those of anaphrodisiacs generally. I must, nevertheless, remark that the anæsthesia of the mucous membranes which attends the exhibition of the bromide of potassium may, and does, prove of great avail in urinary diseases, chiefly to soothe urethral irritation and the consequent erection which under such circumstances is likely to occur.

NOTES OF HOSPITAL PRACTICE.

PHILADELPHIA HOSPITAL.

MEDICAL CLINIC OF DR. H. C. WOOD.

Reported by Dr. W. H. PARISH, Resident Physician.

PNEUMONIA—DEATH FROM GANGRENE OF THE LUNG.

E. C., æt. 37, a native of Philadelphia, was admitted to the hospital on October 7, 1872. On admission, he stated that for five or six weeks he had been suffering with a severe cough, but that he had been confined to the bed for only the last five or six days. His habits had been intemperate in every respect, and he had frequently subjected himself to exposure to severe weather while intoxicated.

The skin was hot and dry; the tongue was somewhat dry and brownish. The bowels were loose, there being three or four passages daily. The respirations were frequent, and the pulse rapid and weak. There was a troublesome cough, attended with an abundant expectoration of a tenacious, rusty, purulent sputum of not especially offensive odor. Auscultation and percussion revealed the involvement of the lower lobes of both lungs, as shown by dulness, bronchial breathing, and the other signs of consolidation.

He was immediately placed on the use of tr. digitalis, gtt. x, every three hours; the effect on the pulse to be watched. He was also given twelve ounces of whiskey in milk-punch, during the twenty-four hours; one-half ounce hourly during the day, one ounce every two hours during the night. An astringent, to control the diarrhœa, was also directed. The chest was enveloped in a hot flaxseed poultice, to be renewed every three hours. It was directed that the diet should consist almost entirely of milk; one quart to be given daily, in addition to that taken in the punch. Dr. Wood, in remarks on the case before the class, stated that beef tea and beef essence possessed very little nutritive effect, and that they should not be relied on as articles of diet for the sick, but may be of some value for their stimulant action. He said, also, that the concentrated extracts of beef now in such general use should not be employed, except to give taste to insipid articles of food, and that in large quantities they are not only unproductive of good, but positively injurious, having in them about twenty per cent. of the potassa salts. These salts are, as had been frequently tested in the lower animals, rapid and decided depressants of the circulatory system.

Dr. Wood also reasoned, that in consolidation of a portion of the lung, as this consolidation shuts off, to a great extent, the entrance of blood, and as the same quantity of blood passes through the heart, the heart's action must be increased in strength to accomplish the more difficult task of driving an undiminished quantity of blood through vessels which in the aggregate would represent a tube of diminished calibre. In digitalis, he claimed, we had a remedy that would give this needed strength to the heart's action,—an effect which has been observed in repeated and undoubted instances.

The patient presented no symptoms of improvement. The diarrhœa was held in check with astringents, but the cough remained very troublesome, and the sputa became much increased in quantity.

On the evening of the 11th there were evidences of delirium of a low type. The temperature, which had been vibrating between 102° and 105° F., fell to 101°, and there was no amelioration of the other symptoms. On the 12th the breath and sputa became quite offensive, with temperature lower than on the previous day, and an increase of the delirium.

October 13.—Pulse 140. Respirations 64. Evening temperature 100; odor of breath and sputa excessively offensive. Delirium very decided.

October 14, 11 A.M.—Temperature 98°. Pulse 120 Respiration 42. 1 P.M., he died.

Dr. Wood presented the specimens to the class on the following clinic day. Portions of the lower lobes of both lungs were in a state of gangrene. An abscess existed in the middle lobe of the right lung. The other portions of both lungs presented solidification, excepting the upper lobes, which contained air. The gangrenous portions were much disintegrated, softened, of a grayish black color, and of a most offensive odor. The other viscera appeared quite normal.

The lecturer remarked that there was an analogy existing between the gangrenous condition following pneumonic consolidation, and that resulting from the application of a ligature. He spoke of the parenchyma of the lungs as being composed of the bronchioles and air-vesicles; the conjunctive tissue binding together these vesicles; the blood-vessels ramifying in this tissue, and furnishing nutrition to the lungs; the nerves and lymphatics and the epithelial membrane lining the air-vesicles. In ordinary acute pneumonia there is an exudation into the air-chambers of a fibrinous material, together with a certain amount of cellular elements. In the course of the disease the exuded *fibrin*, being changed into *mucin*, easily softens down, and the cells take on a fatty degeneration. After these elements are thus changed, they are coughed up or absorbed, and the lung is relieved. But if this exudation, instead of being chiefly fibrinous, consists largely of cells, these cannot change into mucin and in that way soften, but drying and shrivelling they will remain as irritants which the lungs cannot get easily rid of. As the result of this irritation, an inflammation is established in the connective tissue surrounding the air-vesicles, and interstitial pneumonia is thus added to the vesicular form. This interstitial exudation, if thrown out rapidly, into a lung already crowded with inter-vesicular exudation, suddenly compresses the blood-vessels, entirely occluding their calibres, as with a ligature, thus bringing about a form of moist gangrene; which is generally called suppuration, but which, if the powers of the system be low, is accompanied by actual putrefactive changes, and is then known as gangrene of the lungs.

When, however, the exudation is thrown out slowly, the blood is slowly squeezed out of the vessels; the cells clogging up the air-chambers remain as shrivelled masses, and we have the so-called infiltrated tubercles. The infiltrated tubercle is then simply the result of a process consisting of a vesicular exudation, chiefly cellu-

lar; degeneration of these cells, interstitial exudation with gradual occlusion of blood-vessels, and dry gangrene; an explanation so very simple that the wonder is it was not long ago adopted.

Moist gangrene is due to the sudden occlusion of the blood-vessels; dry gangrene, to the gradual cutting off of the blood-supply. Moist gangrene, unless very limited, is of necessity fatal; dry gangrene, if extensive, is also fatal, but if limited may permit the patient's recovery to general good health. If a cavity exists with a limited amount of "infiltrated tubercle," recovery is possible; but if the purulent degeneration is extensive, death is inevitable.

SENILE GANGRENE OF THE NOSE—DEATH.

H. S., æt. 70 years, native of Ireland, and of intemperate habits, was admitted to the Philadelphia Hospital on August 14, 1872, without any positive disease, but with a system enfeebled by old age and the wearing effects of a life of hardships.

On October 1, there was evident congestion of the lungs, with spitting of blood, and with dyspnœa.

On October 12, a small dark point, not larger than a pin's head, appeared on the tip of the nose, with some lividity of the tissue for a few lines around. In this spot there was a sensation of stinging, but no positive pain, it not being mentioned except in answer to questions. This dark spot gradually extended its area, but without any increase in the limited amount of inconvenience. The patient was, however, confined to bed by his feeble condition, and the pneumonic breaking down of the right lung, as evinced by the sputa and the auscultatory signs.

The man being brought before the class, Dr. Wood stated that in this patient we had a man aged not only from years but also from the character of the life he had led. The muscularly laborious men—and especially is such the case if with hard physical toil has been combined intemperance—on arriving at seventy years are older than others are at eighty. In such we find well marked those degenerative changes in the human economy which present themselves as years pass by and old age advances.

You see the black spot on this man's nose; a few days ago it was but a little speck, yet gradually extending it now embraces all of its extremity. It is dry, shrunken, and glazed. This is senile gangrene, due, generally, to atheroma of the walls of the arteries, and occurring most commonly in one of the extremities, most frequently the toes, but also in the fingers, ears, nose, and other points remote from the centre of circulation. The atheromatous or calcareous condition of the vessels, by slowly cutting off the blood-supply, produces, as in infiltrated tubercle, a dead, shrivelled state of the tissues,—the dry or senile gangrene. In cases like this one, there is always a sluggish state of the circulation. In this man we find the ears, toes, and fingers cold and livid, the nails blue, and all the evidences of enfeebled circulatory powers. The gangrene, in this instance, cannot be due to an embolus, *i.e.* it cannot have been caused by a vegetation escaping from a valve of the heart and by means of the circulation entering the facial artery, so as to have occluded one of its ramifications. This cannot be the case, because an embolus would rarely enter the facial artery, but will rather continue in the larger vessel which follows a more direct course, and not enter a smaller one going off at an angle. Besides, if the gangrene were due to an embolus, it would be unilateral, whereas it is here bilateral.

You should be well prepared to recognize the first appearance of this condition. The dark point, like the cloud no larger than a man's hand, trivial as it appears, should forewarn you of what is approaching. It is almost invariably the forerunner of approaching dissolution. Occasionally, as in the lower extremity, a line of demarcation is formed, and the surgeon is justified in removing the offending part, with a possibility of the patient's recovery. Yet such cases are exceptional ones.

For our patient nothing can be done but to render him comfortable. A supporting treatment is indicated, and opium may be given because of its stimulant effect upon the capillary circulation.

[This man died on October 18, 1872, from exhaustion.]

NASAL DIPHTHERIA—DEATH. MALIGNANT CORYZA.

G. A., æt. 58 years, and a native of Germany, was admitted to the hospital on October 12, 1872. It was impossible to obtain any satisfactory account of his past life or of the incipiency of his present trouble. His condition, however, was a typhoid one. His tongue was very dry, brown, and fissured. The pulse was frequent and weak, but the heart's sounds were normal. Physical exploration showed the lungs to be clear, excepting some bronchial râles. The respirations were, however, performed with difficulty, and attended with a peculiar sound, as if the posterior nares were partially occluded. The mucous membrane of the anterior nares was very red and swollen, and there was a thin ichorous discharge. Inspection showed the pharynx, soft and hard palate, and tonsils, to be changed in appearance. They were of darker color than normal, and in spots were covered with an ash-colored exudation. The bowels were constipated. There were great restlessness and jactitation. The evening temperature was 99° F. The administration of half an ounce of castor oil produced four or five fluid evacuations, rendering it necessary to administer astringents. Quinine and iron were directed to be taken every three hours. Milk punch and liquid diet were to be given at regular periods.

On the night of the 13th, there were manifestations of delirium, and a return of the diarrhœa. No tympanitis; no eruption on skin. Temperature at midnight 98° F.

October 14.—Symptoms more unfavorable. Entire mucous membrane of mouth dry and brownish, excepting where covered with the exudation. This had spread over the hard palate; had appeared on the lips and buccal surface, and had become quite dark in color. There was occasionally an escape of a bloody, serous fluid from the anterior nares,—adynamia more marked. The symptoms became more and more decided, until death, which occurred on October 15, 1872.

Dr. Wood presented to the class the specimens obtained at the autopsy. The thoracic and abdominal viscera were apparently normal. A vertical section had been made of the head, passing through the posterior portion of the pharynx, giving a good view of the posterior nares, larynx, fauces, etc. There was a soft, semi-coagulated, ash-colored exudation on the walls of the pharynx, extending through the fauces into the mouth; also into the posterior nares. The mucous membrane of the turbinated bones seemed swollen. There was no exudation in the larynx or œsophagus. Dr. Wood stated that the appearances now confirmed the diagnosis made during life, viz., that of nasal diphtheria; a disease which is generally fatal, in spite of the most prompt and judicious treatment. The ichorous discharge through the nose is an early and diagnostic symptom of the nasal form of diphtheria, and is almost as sure a precursor of death as the dark point on the old man's nose. The patient will complain of the nares being occluded; the nostrils collapse, and there is difficulty in respiration: the local trouble is not, however, the agent of death; the patient does not die of suffocation. The disease is emphatically a constitutional one, and death is due to the general adynamia. All treatment in nasal diphtheria

seems unavailing, but the indications are for supporting and stimulant agents, with such local remedies as copper, tannic acid, etc., in weak solution.

There is a disease of childhood somewhat resembling nasal diphtheria, rarely if ever spoken of in the books. It is a malignant coryza. In this affection there is a very free discharge from the nose of a thick, tenacious mucus,—so free indeed that perhaps a quarter of a pint will be secreted by an infant in the twenty-four hours. This mucus is very different from the ichor of nasal diphtheria, and is unaccompanied by anything like a membranous exudation. With the local trouble there is severe fever, and often from the first onset very marked prostration, resembling that seen in diphtheria. In young children this affection is often very serious, not merely on account of the constitutional but of the local trouble. I have seen the mucus so thick that it would scarcely drop out of the cup when the latter was inverted. The nostrils are absolutely occluded; and the infant, unable to breathe in the ordinary way, rises up in terror, strangling and gasping for breath, and at best is unable to nurse or sleep, from the constant necessity of voluntary breathing. The danger of exhaustion in such a case is twofold: first, from the blood-poisoning; secondly, from the constant effort and the want of nourishment and sleep.

It is, therefore, often absolutely necessary not only that the general strength be supported by the most concentrated diet, by stimulants, by the tincture of iron, etc., but that the nostrils be cleared out. This must be done by injections; and I have found that a solution of the sulphite of lime (grs. xv to ℥j) rapidly dissolves the mucus, and improves the condition of the system, I have used such injections, in some cases every hour, with the apparent effect of saving life.

The child dreads them, and resists them with all his might. But the head should be firmly held, and about an ounce of the solution thrown rapidly up one nostril; this must be repeated on the other side, if the solution does not find its way into the other nostril. In my experience marked benefit follows the use of these injections for a few hours, and though it is often very distressing to give them, they appear at times to actually save life.

UNIVERSITY OF PENNSYLVANIA.

CLINIC OF PROFESSOR AGNEW.

Reported by Dr. Elliott Richardson.

RHINOPLASTIC OPERATION.

THE patient, while serving in the United States Army during the recent war, lost a large part of the fleshy structure of the nose by a thrust of a bayonet.

The nasal bones escaped injury, but the cartilages, the septum narium, and the hard palate were at the time of operation to a large extent deficient, owing to sloughing and necrosis during the treatment of the wound.

It was proposed to attempt the formation of a new nose, by taking flaps from the adjacent surfaces of the cheeks and joining them together in the median line below the nasal bones. The patient was thoroughly etherized, and the operation proceeded with in the following manner. The remaining portions of the lateral cartilages, together with the soft structures attached, were separated from the nasal bones by a transverse incision, and divided into two parts by a vertical cut in the median line. They were then readjusted in a position to correspond with the lower border of the normal nose, and again joined by silver sutures.

The tissues beneath were loosened from their attachments to the bone by an incision made through the mucous membrane of the mouth between the lip and alveolar process.

Two incisions were then carried from the extremities of the transverse cut in a direction obliquely outward and upward on the cheeks for a distance of about three-quarters of an inch, and the tissues covering the nasal bones detached from these by subcutaneous dissection, extending upwards from the original transverse cut. During the operation some old cicatricial tissue was removed, its presence tending to induce contractions inimical to the success of the operation. It will thus be perceived that two wings were made by the oblique incisions, which could be brought together and placed in the space left between the nasal bones and the flaps composed of the lower structures of the nose made by the first steps of the operation. This was done, and the flaps united with each other and the contiguous cut surfaces by silver sutures. The wounds in the cheek were also approximated in the same way, and supported by strips of adhesive plaster. The operation was of necessity attended with a good deal of hemorrhage, which rendered the application of a few ligatures necessary. Prof. Agnew said that in plastic operations, in order to secure the vitality of the flap, it was necessary to avoid as far as possible the division of important vessels of supply, and to cut down into the fat and connective tissue. Care should be taken, also, to include an apparent redundancy of tissue in the flaps, to compensate for the subsequent shrinkage.

Nov. 8 (four days after the operation).—Stitches all removed yesterday. Double nasal tubes were introduced the day after operation, and since retained. Simple wet compresses were kept applied until yesterday, when dry dressings were substituted. The flaps appear to be uniting to some extent by first intention, but partially by granulations.

Subsequently a small line of slough formed along the edge of one of the lower flaps, and prevented union, rendering another operation at some future time necessary to effect the desired object.

EPITHELIOMA OF HAND.

The patient, a man aged 64 years, had upon the dorsal surface of one hand an obstinate ulcer about an inch in diameter. The edges of this ulcer were elevated and indurated, the granulations unhealthy in character, and the discharge an offensive purulent matter. A few dried clots of blood around the edges gave evidence of slight hemorrhage at times, and the general appearance of the diseased surface, when taken with its history, clearly indicated its malignant character.

The disease first made its appearance about one year ago, as a little wart covered by a thin crust, no injury to the part being known as a cause. This crust being rubbed off would leave a small red point, which would again scab over. After a time a discharge of serum began, which was soon followed by ulceration and the formation of pus. On the side of the nose a similar growth was observed in its early stage, appearing as a small, scaly wart. Prof. Agnew said that the edges of these ulcers were generally, as seen in this case, hard, elevated, and somewhat everted, and that when subjected to irritating influences they were surrounded by a reddened surface, but often the skin was perfectly healthy to within a short distance of the border of the ulcer. This disease spreads by infiltration, and is to a great extent a local disorder, which can generally be effectually cured by the removal of the diseased tissues. Removal may be accomplished by caustic applications, but in most cases excision is preferable.

The patient being etherized, a circular incision was made around the ulcer about half an inch from its border, and the diseased surface and subjacent structures

down to the deep fascia removed. The integuments were dissected up for some distance around, in order to render a greater degree of approximation of the edges of the wound possible.

The wound was then nearly closed with strips of adhesive plaster, a wet compress applied, and the arm bound upon a splint, thickly padded at the end, so as to retain the hand in a position strongly flexed backwards. Ten days after the operation the wound presented a healthy granulating surface, and recovery seemed assured.

NEUROMA OF ULNAR AND OTHER NERVES.

This patient was a woman, aged 44 years, who applied for relief on account of a neuromatous tumor of the ulnar nerve, near the wrist. Seven years ago she came to Philadelphia, and was operated upon for the removal of a similar growth, situated near the elbow-joint. She has had three operations performed since; one at the right wrist and subsequently two at the left wrist, all for the removal of tumors of the same nature.

In addition to the one at the wrist, the patient now has one situated in the neck and one at the right elbow. She suffers a good deal of pain and some loss of power in the right arm. She was etherized, and the tumor removed. It was of small size, and fibrous in its nature, and its removal was accomplished through an incision little more than an inch in length. Under the local application of laudanum and water, union soon occurred.

FATTY TUMOR.

Professor Agnew removed a large fatty tumor from a woman 35 years of age. The growth was situated on the right side just above the crest of the ilium. It was first observed twelve years ago, and had grown slowly and without pain to this date. The tumor was removed by making a vertical incision through the integuments over its surface and dissecting it from the slight bands of adhesion to the surrounding structures. It was found to have projecting from its lower surface a process, which dipped down and curled under it like the neck of a squash. Two ligatures were applied to small arteries, and the wound closed by silver wire sutures and adhesive plaster. Over these a compress of dry lint was applied. Professor Agnew called attention to the important diagnostic points in this case, distinguishing the tumor from malignant growths.

The length of time was important, for cancerous tumors are usually very rapid in their growth, life often being destroyed by them in two or three years, although in very rare cases they have been known to run a course of eight or ten years. The absence of pain is another important characteristic of fatty tumors; cancer being generally attended by sharp lancinating or shooting pain. In cancer also, when developed to any extent, the general health becomes seriously affected, giving rise to the characteristic cancerous cachexia; while in fatty growths the system is entirely free from any contamination. The doughy, lobulated feel, and the sensation almost of fluctuation, as well as the mobility of the tumor and of the skin over its surface, present in this case, all pointed unmistakably to the nature of the growth. These tumors are composed of fat and connective tissue, not differing essentially from these structures found in other parts of the body, and are but feebly supplied with blood-vessels. They may be disseminated and without any distinct boundary, but are generally enclosed in a sac composed of two layers of connective tissue, thickened and indurated by the gradual pressure of the tumor exerted by its growth. The inner layer is much more adherent to the tumor, and the outer layer to the surrounding structure, than the two layers are to each other: hence the tumor, with its enveloping membrane, moves freely and can generally be liberated from the other by the finger or other blunt object passed between them, except at the point of vascular communication, where the union is firmer. These tumors are most commonly met with in the back and neck, though most other parts of the body are sometimes their seat, and cases are not unfrequently met with in which large numbers of them are found scattered over the neck, trunk, and extremities. They are usually superficial, but sometimes occupy deeper situations.

Their removal is generally unattended with danger, except in cases which sometimes occur where they are found to dip down among important vessels and nerves.

They are inconvenient from their size and weight, and sometimes dangerous from pressure upon vital parts, but with these exceptions they are unproductive of alarming symptoms.

A Case of Double Vagina and Uterus. By D. M. Edgerly, M.D. (*Boston Med. and Surg. Journal*, October 26).—The patient in whom this anomaly occurred was a poor Irishwoman, 35 years of age, pregnant with her first child. Labor commenced Monday morning about five o'clock. Hoping to get through without calling a physician, she did not send for me till Wednesday noon,—nearly sixty hours after labor supervened.

When I arrived, I found the patient very much exhausted; the pains were irregular, weak, and inefficient. Upon making a digital examination, I found the head low down, and the pelvis capacious; the finger could easily be carried around the portion of the child's head occupying the right half of the maternal pelvis. But when I attempted to carry my finger over the part occupying the left half, it came in contact with what seemed to be a membrane drawn tightly over the presenting portion of the head in the median line, extending antero-posteriorly. My first impression was that a lip of the os uteri was caught on the child's head and was obstructing its progress. But all attempts to get at that side of the head, either by carrying my finger under the membrane or passing it outside, failed. I found a membrane, continuous with that confining the child's head, extending to the outlet of the vagina. After making this discovery, I withdrew my finger, and found I could easily introduce it on the other side of the membrane, and feel the outline of the as yet inaccessible part of the head, but with a thick membrane intervening between it and my finger. Crowding the finger deeply down beside the head, it came in contact with what seemed to be a small cervix and os uteri. The condition of things was now evident. Withdrawing my finger and again introducing it on the right side, I partly succeeded, by using considerable force, in slipping the septum off the fœtal head. I then gave ergot in large doses, which failed to invigorate materially the uterine contractions. After waiting a little I applied the forceps, and, with some difficulty, delivered the woman of a still-born child. Appearances indicated that it had been some time dead.

The woman made a rapid and complete recovery.

When the lochial discharge had ceased, I made another examination, entirely confirming my opinion of the state of affairs at the time of confinement. On the right side I found a vagina of ordinary size, and a uterus rather larger than normal, involution not being yet completed. On the left side was a small vagina, not large enough to admit a medium-sized glass speculum,—the smallest I had with me,—also the cervix of a rudimentary uterus; the body of the second uterus could be felt resting on the cervix of the one which had been impregnated.

PHILADELPHIA
MEDICAL TIMES.
A WEEKLY JOURNAL OF
MEDICAL AND SURGICAL SCIENCE.

The Philadelphia Medical Times is an independent journal, devoted to no ends or interests whatever but those common to all who cultivate the science of medicine. Its columns are open to all those who wish to express their views on any subject coming within its legitimate sphere.

We invite contributions, reports of cases, notes and queries, medical news, and whatever may tend to increase the value of our pages.

All communications must bear the name of the sender (whether the name is to be published or not), and should be addressed to Editor Philadelphia Medical Times, care of the Publishers.

PUBLISHED EVERY SATURDAY BY
J. B. LIPPINCOTT & CO.,
715 and 717 Market St., Philadelphia, and 25 Bond St., New York.

SATURDAY, NOVEMBER 23, 1872.

EDITORIAL.

QUACKERY IN INDIANA.

WE have received from an unknown source one of the most stupendous advertisements of a quack concern that we ever remember to have seen. It is issued by "The National Surgical Institute," which would seem to be located in Indianapolis. It claims to be a chartered institution, with a capital stock of $500,000, and to have connected with it "none but surgeons of ability, honor, and long experience in this specialty:" the names of these ornaments to the profession are given, but are, unfortunately, unknown to fame. Dr. H. R. Allen and W. P. Johnson have a copyright, it appears, in the circular.

A vast array of woodcuts of deformities and diseases, many of them old and familiar acquaintances, "as received," and a number of others, from fashion-plates we think, "as dismissed," are put forth to show the wonderful successes which these honorable gentlemen have achieved. Governors, judges, auditors-general, and a fair sprinkling of the clergy, are the endorsers of this establishment, to which, says the circular, "thousands of our best physicians send their surgical cases for treatment," and "find it to their interest, pecuniarily."

One strong point of the institution seems to be piles and fistula, and there is a short paragraph headed "private diseases—a great revolution," which we cannot but think is meant to indicate another. None of the ordinary opprobria of surgery, however, appear to offer serious obstacles to the genius of these "honorable and experienced" gentlemen.

Our unknown correspondent makes a marginal note that the country is being flooded with these quack advertisements; and we do not doubt it. The wonder is, not that they are issued,—for there are always fools ready to be gulled by them,—but that Governor Baker of Indiana, Governor Oglesby of Illinois, Senator Hendricks, and a number of other known high officials, clergymen, judges, and editors, are willing to lend their names to a scheme for fleecing the afflicted under false promises of cure.

How are such things to be put down? We believe that the only way is to take a few of the victims and make their cases the ground of suits against these swindlers for obtaining money under false pretences. We feel confident that before long the end of the "capital stock of $500,000, invested," say these traders in human misery, "in obtaining the needful appliances," would be reached; and we much doubt whether the aforesaid governors and judges would come forward to give bail to prevent their protégés from the imprisonment they so richly deserve.

It is all very well to laugh at the clever tricks of such quackery; but there is another side to the picture. Who shall paint the scene adequately? In how many a simple, honest farmer's or laborer's family is there a lame or diseased child, to whom a gleam of hope comes that he may be restored quickly and without pain to health and activity! The parents summon all their resources; they borrow and beg; they take a toilsome journey, sacrifice time, money, trouble, that their afflicted one may find the promised relief. A "payment in advance" is of course demanded; a form of treatment is gone through with, until there is no more money to be extorted from them, and then they are told, "You did not come to us soon enough," and the sufferer is remanded to despair; his case, however, is vaunted as a fresh triumph, with a false picture of his condition "as dismissed," and made a decoy for other victims.

DARWINISM.

MANY excellent persons are much exercised about the Darwinian theory, which they think is hostile to the interests of every religious belief. They forget, as did the opponents of geological science not very long ago, that two truths cannot clash. If "Darwinism" is well founded, it must

be in accord with every other fact, whether of natural, moral, mental, or spiritual philosophy. If it is inconsistent with any accepted law, one or the other must inevitably fall; and as inevitably it will be the true that will stand, the false that will perish.

Let the faint-hearted take courage from the lines so often quoted, but too good ever to lose their force:

> "Truth, crush'd to earth, will rise again;
> The eternal years of GOD are hers;
> But error, wounded, writhes in pain,
> And dies among his worshippers."

We cannot, however, see that the theory of Darwin need at all militate against revealed religion. This is a matter of man's inner consciousness, not to be sustained by any array of logic, but resting upon its fitness to supply his felt needs. He finds himself endowed with an immaterial nature, unsatisfied by material things; and this truth remains, whether his remotest ancestor was a monad or an angel. At some past period, the Godlike image was impressed upon the human frame, and the power to know, to reverence, and to love his Maker was bestowed upon the soul within it. To fear that any discovery of science can alter or destroy this gift, is unworthy of those who have received it.

THE CHLOROFORM QUESTION.

AN apology can hardly be needed for again bringing this matter before our readers. It is too important to be left undiscussed; and we are the more urgent in pressing it, because the adherents of chloroform say nothing. They cannot deny that hundreds of lives have been sacrificed to their favorite anæsthetic, and yet they do not explain why they subject others to its fearful risks.

One most important point we do not remember to have seen noted by any of those who have opposed the use of this article; and that is, that impunity on one occasion does not insure immunity on the next. We have ourselves seen chloroform given apparently with perfect safety to a patient, who, three or four weeks afterwards, died while inhaling it for a second operation.

If between two points there were two roads available, over one of which hundreds of thousands travelled safely every year, while of those who took the other a certain percentage, however small, mysteriously failed to reach their journey's end, we think the latter would soon become grass-grown.

CORRESPONDENCE.

THE EQUINE INFLUENZA.

TO THE EDITOR OF THE PHILADELPHIA MEDICAL TIMES:

SIR,—It may interest some of your readers who have not had the time or the curiosity to inquire into the nature and significance of the epizoöty which now prevails among horses, to know that similar epidemics have been of very frequent occurrence, and that they have often preceded or accompanied the influenza in the human race. In many instances the animals have suffered a month or even two months before the outbreak of the disease among mankind; and it may therefore be well for those of us whose ideas upon the subject are neither definite nor clear, to prepare for the approach of influenza by a study of its peculiarities of type, and of the very different treatment it requires from that of ordinary catarrhs.

I transcribe from the "Annals of Influenza" (Syd. Soc. ed., 1852, p. 374) the following passage, which summarizes the numerous facts relating to the subject which are contained in the volume:

"The poisonous influence has not been confined to the human species. In this respect, influenza is not peculiar. The plague described by Homer first broke out amongst the dogs, then seized the mules, and lastly made its attack on man; and it is natural that animals constantly exposed to the weather should be subject to diseases connected with atmospheric distemperature, but in no disease is this kindred liability more manifest than in epidemic catarrh.

"Cows and horses have especially suffered, as is observed in the epidemics of 1733, 1737, 1743, 1803, 1831, and 1837.

"Dogs, cats, deer, sheep, and swine have not enjoyed any immunity; poultry also, and even fish, seem occasionally to be affected with the morbid influence.

"As respects horses, there is reason to believe that close stables have had considerable effect in promoting the diffusion and increasing the virulence of the disorder, and, indeed, that the congregation of many animals in the same stable, however spacious, has an unfavorable influence.

"Analogous facts may be collected from our Navy Returns of the Mediterranean Service, in the years 1832 and 1837."

Æ.

"EIGHT CHILDREN AT ONE BIRTH."

TO THE EDITOR OF THE PHILADELPHIA MEDICAL TIMES:

DEAR SIR,—Through the kindness of an Ohio correspondent, I am able forever to set at rest the story with the above heading, which is now going the rounds of the medical press.

Mr. Timothy Bradlee, of Johnston Township, Trumbull County, Ohio, is a well-to-do farmer, Democratic politician, and practical joker, often trying his skill even upon his most intimate friends; and, as such men's

chickens often come home to roost, some four or five years ago one of his jokes was retorted upon him in the getting up of a hoax that his wife had brought him eight children at a birth, and, to add to the fun, named the boys after noted Republican politicians. This story was started in private, by a well-known army general and member of Congress, now deceased, whose name need not be mentioned, in return for a trick played upon himself by "Tim Bradlee," as he is generally called, and was a current report in his own neighborhood, where he is well known, until it was finally fully distributed and worn out. It was revived last summer in a Cleveland paper, by another victim, out of revenge; and hence its getting away from a locality where, from the nature of the original story, it told its own tale and deceived no one. R. P. H.

OBITUARY.

DR. GEORGE PEPPER.

IN a recent issue we briefly alluded to the death of this exemplary medical gentleman, the younger son of the late Dr. William Pepper, the distinguished Professor of Practice of Medicine in the University of Pennsylvania. His services to the profession necessarily embraced but a few years of active personal labor, for he died at the early age of thirty-one; but in the brief period which elapsed from his graduation, in 1865, he held numerous positions of trust and honor. He commenced the study of medicine in 1862, but temporarily abandoned it to enter the army as a private in the Sixth Pennsylvania Cavalry, becoming afterwards promoted to a lieutenancy, and was honorably discharged the following year for disability, in consequence of a troublesome dislocation of the clavicle, caused by his horse falling with him while crossing a frozen stream. He was a member of the various medical and scientific societies of our city, Treasurer of the Pathological Society, Secretary of the Obstetrical Society, Physician to the Magdalen Home, Accoucheur to the Philadelphia Hospital, Assistant Physician to the Nurses' Home, Corresponding Member of the Gynæcological Society of Boston, etc. He published numerous short articles in the Proceedings of the Pathological and Obstetrical Societies; an interesting case of Retroversion of the Uterus, in the Pennsylvania Hospital Reports for 1868, etc. As a lecturer he devoted himself especially to the diseases of women, on which he gave clinical courses for several years at the Nurses' Home, Philadelphia Hospital, and elsewhere. His practice was speedily acquired, and grew rapidly, but he was not physically adapted to permanently endure its hardships, having, from the early part of 1871 especially, suffered successively from typhoid fever and pneumonia; his final illness, which terminated on the 14th of September last, being of a lingering nature, and marked with many changes of condition.

The character of Dr. Pepper was distinguished by unusual single-mindedness and guilelessness; by warm affections, rare high principles, and a most love-winning nature. He was possessed of an unusually retentive memory, and of remarkable artistic power and mechanical ingenuity. As a physician he was accomplished, enthusiastic, and devoted, and early exhibited a therapeutic skill, especially in his favorite branch of gynæcology, which rapidly led to success.

PROCEEDINGS OF SOCIETIES.

BIOLOGICAL AND MICROSCOPICAL SECTION OF THE ACADEMY OF NATURAL SCIENCES.

DIRECTOR W. S. W. RUSCHENBERGER, M.D., in the chair.

Present,—Prof. Joseph Leidy, and Drs. Tyson, I. Norris, J. G. Hunt, Wells, Hartshorne, McQuillen, and Richardson.

Visitors,—Dr. Penrose, U.S.N., Dr. Deschert, and Dr. Noels, of San Francisco, California.

Dr. JAMES TYSON made a very interesting verbal communication upon the subject of Practical Histology in Germany, giving an account of the Pathological Laboratory of Prof. Stricker in Vienna, and of the methods employed by the students under his supervision, describing particularly the modes there in use for demonstrating connective tissue, muscular structure, the terminal plates of nerve-fibres, etc., also the usual methods of gold and silver staining and of mounting objects for permanent preservation.

The Director inquired how long any specimen was allowed to soak in lime-water when preparing it for dissecting the connective-tissue fibrils, as had just been suggested.

Dr. TYSON replied that no particular time could be specified, and, in fact, the completion of the process was only to be determined by trial of small fragments by dissection with needles at intervals, so that sometimes one, two, or three days were occupied in making the preparation.

Prof. LEIDY asked how any adherent particles of wax were removed from the edges of thin sections of tissue which had been cut from specimens after undergoing the process of imbedding as the doctor had just described it.

Dr. TYSON replied that practically little difficulty was experienced, as the particles of wax were found to fall off generally of themselves when the section was floated off in alcohol.

Prof. LEIDY further inquired whether Dr. Tyson had become acquainted with the method by which thin transverse sections of minute animals—as, for example, the Anguillula aceti—were prepared.

Dr. TYSON replied that he had not seen such sections made, but believed they could be accomplished by cutting at random through great numbers of the objects in question and then picking out the sections which happen to be made in the manner required.

Dr. J. G. HUNT remarked that we have now an improved cell, specimens of which were last spring exhibited before the Section, which was so ingeniously contrived as to show perfectly thin transparent objects in all portions without the need of making sections; moreover, he observed, there was no need for imbedding them or other objects in wax, since a cheaper and more convenient substance for the purpose could be found in the ordinary paraffine of the shops. In regard to the water-beetles mentioned by Dr. Tyson as furnishing to German microscopists their favorite specimens for demonstrating the Doyerian plates, he stated that the same or a closely-allied species was abundant in our own creeks and ditches, and could readily be obtained by every one for investigation.

Prof. LEIDY explained, by the aid of drawings upon the blackboard, that what he wished to understand was how a transverse section of a vinegar eel, for example, or of the intestinal canal of a very minute insect, as figured by some German naturalist, was prepared. He also remarked that no observation of entire organisms,

either in improved or unimproved cells, could give the kind of information respecting internal structure afforded by such sections as he referred to.

Dr. J. G. HUNT thought perhaps the drawings mentioned by his friend Prof. Leidy were only diagrammatic, and suggested, moreover, that the binocular microscope would often, in such researches, do away with the necessity for a dissection.

Dr. J. G. RICHARDSON inquired what was the exact status at present of Prof. Stricker and his disciples in the controversy with Prof. Cohnheim respecting the origin of pus-corpuscles in inflammation.

Dr. TYSON replied that Prof. Stricker continues to hold that Virchow's and Cohnheim's views are both partially correct,—*i.e.* that the leucocytes of pus arise both from the proliferation of the proper cells of the inflamed tissues and from the wandering out of the white blood-corpuscles through the walls of the vessels.

Dr. HUNT proposed that a committee be appointed, at some suitable time, to compare and report on methods for the preparation and mounting of specimens, and thought that their decision would have a practical value to microscopists throughout the country.

Dr. TYSON further observed that he considered Dr. Klein, now of London, the most expert teacher of microscopy he had ever met, and believed that if opportunities continued to be afforded him in England for carrying out his methods of instruction, no one need go further than Klein's laboratory to obtain a complete knowledge of microscopic manipulation.

GLEANINGS FROM OUR EXCHANGES.

SNAKE-BITES.—In an article on Dr. Fayrer's recent work on the poisonous serpents of India, the *Brit. and For. Med.-Chir. Review* (October, 1872) says, "The fatality from snake-bite in the presidency of Bengal appears to be frightfully high. In the year 1869 there were upwards of 11,000 known and reported cases, and the number of unreported cases was probably not much less. A liberal system of rewards for dead snakes would undoubtedly lessen the evil.

"If Dr. Fayrer's work had done nothing else than show the utter inutility of all the so-called antidotes, whether of native or European origin, against the bite of the more poisonous of the Indian serpents, he would have rendered good service. Inutility is, in truth, not a sufficiently strong word to use with regard to them, for reliance upon them has often bereft the unfortunate victim of his only chance, by consuming the precious time which should have been employed in the use of the ligature, excision, and cautery. Ammonia, aristolochia, arsenic, Tanjore pills, eau de luce, liquor potassæ, numerous native remedies, snake-stones, the injection of ammonia, potassa, Condy's fluid, have all been tried, and were all found equally unavailing when an animal had been fairly bitten by a vigorous cobra. But both cases and experiments confirm the value of the ligature when tightly and promptly applied above the bite, and followed by speedy excision and the application of the actual cautery, or of strong nitric acid; or, better still, in the case of a finger or toe, by immediate amputation at the next joint above. The following is Dr. Fayrer's summary of all that he thinks can be done:

"'I would summarize the treatment of snake-bite as follows: Apply at once a ligature or ligatures at intervals of a few inches, as tight as you can possibly tie them, and tighten the one nearest to the wound by twisting it with a stick or other such agent. Scarify the wound and let it bleed freely. Apply either a hot iron or live coal, or explode some gunpowder on the part, or apply either carbolic or some mineral acid, or caustic. Let the patient suck the wound whilst you are getting the cautery ready, or if any one else will run the risk let him do it. If the bite be on a toe or finger, especially if the snake has been recognized as a deadly one, either completely excise or immediately amputate at the next joint. If the bite be on another part, where a ligature cannot be applied, or, indeed, if it be on the limbs above the toes or fingers, cut the part out at once completely. Let the patient be quiet. Do not fatigue him by exertion. When, or even before, symptoms of poisoning make their appearance, give eau de luce, or liquor ammoniæ, or carbonate of ammonia; or, even better than these, hot spirits and water. There is no occasion to intoxicate the person, but give it freely, and at frequent intervals. If he become low, apply sinapisms, and hot bottles, galvanism, or electro-magnetism, over the heart and diaphragm. Cold douches may also be useful.'"

DIAGNOSIS OF TUBERCULOSIS (Dr. M. Heitler, Vienna: *Wiener Mediz. Presse*, October 6, 1872).—The diagnosis of tubercle is not ordinarily difficult; the appearance of the patient and the history of the case often render an examination superfluous, excepting for the purpose of a more thorough knowledge of the extent of the ravages of the disease in the lung. Every physician of experience, however, knows that there are some cases in which it is difficult to to say whether tubercle is present or not in the diseased lung. The disease does not always occur in its characteristic form, but in a group of symptoms by which we may often be misled. Not only miliary tubercle offers no sure means of recognition, but also the subacute and chronic forms present many difficulties to the diagnostician, in their stage of development, by a group of symptoms which belong also to other diseases, and which mask the tubercular nature of the disease in question.

Very frequently a patient comes complaining of palpitation of the heart, a weak stomach, and other digestive troubles. He says "he has no disease of the chest, and has never been troubled by a cough," etc.; but if we continue our questions we discover that in many cases a slight weakness has been noticed by the patient, and that he has commenced to grow thin, he knows not why, and that he has night-sweats: others say they have noted none of these latter symptoms, but that they suffer from palpitation of the heart, dyspepsia, etc., and they think they have heart-disease or disease of the stomach.

If we examine such persons, we find nothing abnormal in the organs of circulation or digestion, but we may find a marked dulness in the apices of the lungs. However, not only symptoms characteristic of other diseases may render the diagnosis of tubercle difficult, but the pulmonary symptoms themselves may at times render the diagnosis of tubercle doubtful or improbable. It sometimes happens that the tubercular disease is ushered in under the form of a broncho-blennorrhœa with copious mucous expectoration, and in the lungs we find symptoms of catarrh only.

In such cases, however, the marked increase in the emaciation, the weakness and continued fever, lead us naturally to a repeated examination of the chest, and very soon we discover dulness on percussion, with other characteristic symptoms.

The most difficult cases are those where we have to diagnose between a croupous pneumonia undergoing resolution, and a tuberculosis. It is often impossible at the first examination to decide the nature of the disease; and a period of observation extending over several days is necessary in order to make a positive diagnosis.

In other cases we can at once, by means of the physi-

cal signs and the history of the case, establish the diagnosis. If, for example, we find a symmetrical dulness extending over the entire lung, accompanied by a consonating subcrepitant râle, or bronchial breathing, with fever, and if we discover that the disease has reached that point, or passed it, when, if it were an ordinary pneumonia, resolution should have commenced, —*i.e.* the beginning, or, at latest, the middle, of the second week,—we are justified in supposing that we have to deal with a case of tuberculosis, and not with one of pneumonia in the stage of resolution.

I lay special stress on the similarity of the physical signs found throughout the tubercular lung; whereas in the lung of a patient affected with pneumonia we may find fine vesicular breathing at the base, while above there are various râles, and bronchial respiration. In tuberculosis the part first attacked does not become free as the process of disease spreads throughout the lung, and at last we may hear the same sounds at all points in the lung.

There are other cases in which a positive diagnosis can only be made from the history and the course of the disease. Suppose we find in the upper portions of the lungs a dulness, with consonating subcrepitant râles, confined either to a very small spot, or extending over the greater part of the superior lobe of the lung. If the individual is anæmic, and states that he has already had fever and a cough for several weeks, and that the latter preceded the fever, and that emaciation has been slowly progressing, we may safely conclude that the physical signs indicate the commencement of a tubercular infiltration, and not the resolution of a croupous pneumonia.

In many cases the history and the appearance of the patient furnish no sure guide to a diagnosis of tubercle. In many cases the individual has been perfectly well, has a well-formed thorax, and looks pretty well at the time the diagnosis is made. In such a case only a consideration of the physical signs attending a pneumonia in an advanced stage of resolution, and the course of the disease, can render our diagnosis beyond doubt. In a few days the diagnosis will become clearer, the circumscribed dulness, which sometimes remains stationary quite a long time, will suddenly spread, the fever will continue very high, and the patient will rapidly fall into a state of collapse, with all the symptoms of well-defined tuberculosis. Dr. Heitler will continue his reflections upon this subject, which he has ample opportunity for studying in the wards of the "Allgemeines Krankenhaus" in Vienna.

Hearing One's Own Voice through the Eustachian Tube (Prof. Rüdinger, of Munich: *Monatsschrift für Ohrenheilkunde*, September, 1872).—In this article Prof. Rüdinger adduces what he considers a proof that in the normal condition the Eustachian tube is closed.

While lecturing, the Professor performed the ordinary act of swallowing, and heard the usual cracking sound in each ear, accompanied by the temporary sensation of opening of each tympanum. In the right ear, however, the sensation continued, attended with an increased perception of the words which the Professor was uttering in his lecture.

He says, "My own voice appeared to me to be higher and of another 'clang-tint' or timbre (clang-tint has been proposed by Tyndall as a translation of the German word 'Klangfarbe'), and at last became painfully audible." This continued for some moments; but at last the Professor, unable to endure the pain, swallowed, and the phenomenon disappeared. Rüdinger says, "I have no other explanation of the supposition that as I performed the act of swallowing, a spasmodic condition of the dilator tubæ occurred, than my own peculiar subjective sensation.

"The continuation of the cracking sound and open sensation in the right ear seems to show primarily that a spasmodic contraction of the muscular portion of the Eustachian tube occurred; and, as instantly my own voice with altered clang-tint was heard as if through the Eustachian tube, the supposition seems natural that the tube was in a very different condition from its ordinary one.

"All the phenomena seem to indicate a spasmodic patulence of the Eustachian tube, rather than a spasmodic contraction of the stapedius muscle or the tensor tympani, which some might suppose had taken place."

If the observation and indication are correct, we may conclude that the Eustachian tube is closed in the normal condition, in the manner I have elsewhere described, and that it must be closed in order that our own voices may not be heard to a painful degree by ourselves, through it.

C. H. B.

The Various Applications of the Irrigation-Apparatus ("Ueber die vielfache Anwendung des Irrigationsapparates:" *Wiener Mediz. Presse*, 33, 34, 36, 1872).—By Dr. Seyfert, of Oderan.

The apparatus alluded to in this work is that which is usually known in our country as "Thudichum's douche." It is more properly called Weber's nasal douche, from its discoverer, Ernst Heinrich Weber, of Leipsic.

Weber, while making his experiments upon the sense of smell, discovered that if a stream of water is passed through one nostril into the naso-pharyngeal space, the soft palate is made to rise reflectively and close the communication between the naso-pharyngeal space and the pharynx. The stream of water, having no other means of escape, returns by the way of the opposite nostril.

Theodore Weber, of Halle, was the first to make use of this physiological fact clinically.

This method of applying medicated solutions to the nostrils, pharynx, and even the tympanum, has been widely used, with good results; although within a few years much has been written against its use, by distinguished men.

Seyfert lays down three leading principles to be observed in the application of the nasal douche, viz.:

1. The vessel containing the fluid to be injected must be *not higher* than the forehead of the patient.

2. The forehead must not be inclined forward; if it is too much inclined, the fluid enters the frontal sinuses.

3. The fluid used in every case must be tepid, and in bad weather the patient should not leave the room for a quarter of an hour after the use of the douche.

Dr. Seyfert says he has never known a case of secondary inflammation to occur where these rules have been observed.

Although many have written in unfavorable terms of the use of this means of treatment, the author says he has never seen any bad results from the use of the douche, during a considerable experience in the clinic of Prof. Wendt in Leipsic,—where it has always been used with the careful observance of the rules already given.

The author says he is convinced that in the alleged unfortunate case (*Moos and Knapp's Archives*, vol. i.) some error in the use of the apparatus must have occurred, especially in respect to the height of the vessel above the forehead.

C. H. B.

New Treatment of Urethral Stricture.—*Le Mouvement Médical* quotes from the *Gazette Hebdomadaire* of August 9 the following acount of a plan advocated by M. Coze, formerly Professor in the Faculty of Medicine at Strasbourg:

"In some cases of very narrow stricture, the employment of a sufficiently powerful pressure by means of

liquid facilitates greatly the introduction of bougies which could not pass a few minutes before.

"The apparatus is very simple, and easily made. It consists of a funnel with a rubber tube, the tube having a stop-cock, and ending in an attachment to a glass pipe with a rounded end. The funnel, filled with water, is raised to any desired height, and the stop-cock turned so as to let the water flow to the end of the glass tube, which is then inserted into the urethra, and the force of the column of liquid brought to bear on the stricture.

"The advantages claimed for this plan are—1. That it is efficient. 2. That it is painless and safe. 3. That the dilatation effected by the water can be kept up by the continued retention of instruments.

"M. Coze thinks the water used should have been boiled, to avoid the introduction of germs or other injurious matters into the bladder.

MISCELLANY.

Modern Giants.—The race of giants is not extinct; and Barnum might make a fortune by bringing over the Goshen family from Turkey in Asia, who are descendants of the Anakims of Palestine. Colónel Ruth Goshen, thirty-three years old, one of this family, now residing in Algonquin, Illinois, born among the hills of Palestine, and seven feet and eight inches in height, recently entered the office of the *Scientific American*. He is the fifteenth and last child (the baby) of a family of fifteen,—ten sons and five daughters,—sired by a patriarch now ninety years old, living in the valley of Damascus, and by occupation a coffee-planter. This venerable sire weighs at the present time five hundred and twenty pounds avoirdupois, and his wife, aged sixty-seven, weighs five hundred and sixty pounds. The entire family are living, and not one of them weighs less than five hundred pounds. The oldest son weighs six hundred and thirty pounds, and the youngest (the Colonel), outstripping them all, weighs six hundred and seventy pounds. Not one of the family is less than seven feet in height. Ruth was a colonel in the Austrian army in 1859, and a colonel commanding in the Mexican army at the battle of Pueblo, May 5, 1862, in which the Mexicans were victorious. His father at one time resided at Leeds, England, but returned to Turkey in 1845. The colonel married in Leipsic, Germany, a woman weighing one hundred and ninety pounds, and five feet nine inches in height; the union has been blessed with two sons, who give promise of rivalling their father in stature. He is a finely-proportioned man; walks with a firm and elastic step; is as straight as an arrow, and has coal-black eyes, hair, and moustache.

The Government at Constantinople have just determined that instruction in the Imperial School of Medicine shall be given in Turkish, and have removed all professors who cannot speak the national language. The Turks say they started their school as a national school, and not as a foreign one. The authorities have therefore determined to run the risk of the change, and to attempt to get for this school, as for others, books and teaching in the vernacular. They maintain that, as medicine has for ages been taught in Arabic, it can be taught in Turkish. Several French-speaking professors have spent many years in the country, and have not chosen to acquire the language.

A man was sentenced to death at the Old Bailey who had a wen upon his throat weighing between thirty and forty pounds. To hang him was impossible without circumstances of revolting cruelty. The case found its way from the lawyers to the surgeons; the latter obtained his pardon, and took off the tumor. John Hunter was the operator. The man, his offence not having been of a very heinous kind, though the laws made it at that time capital, was taken into his service, and used to show his own wen in his master's museum. The facts are narrated in Southey's "Doctor."

Suicide of Professor Treitz, of Prague.—Dr. Treitz, who has been for the last twenty years a most popular Professor of Anatomy in the University of Prague, has recently, in a fit of melancholy, destroyed himself by means of cyanide of potassium. Notwithstanding the great popularity of his teaching among his pupils, out of his theatre Treitz was never accessible, having had for years past the reputation of being a "man-hater."

The first number of the *Chicago Medical Register and Directory* has been published by a book firm of that city, under the supervision of Drs. Freer, Davis, Byford, and others. In the cities where similar works have existed for some years, they are considered not only useful, but indispensable in the office of every active physician.

New University.—A new university was announced to be opened on the 1st inst., at Klausenburg, the capital of Transylvania. The town already possessed a Medico-Chirurgical School, the teachers in which were to be professors of their respective subjects in the Faculty of Medicine of the new institution.

The *Medical and Surgical Reporter* says that the old buildings of the Maryland Hospital, Baltimore, Md., are to be torn down shortly, to give place to a more imposing structure under the munificent endowment of Johns Hopkins, Esq., amounting to $2,000,000, to be known as the "Hopkins Hospital," for the benefit of people of color.

False Certificates of Vaccination.—Dr. Thomas Black Webster, Isle of Skye, has been convicted at the Inverness Circuit Court of fabricating false certificates of vaccination. There were twenty charges proved against the defendant, and he was sentenced to four months' imprisonment.

Drowned in the Discharge of Duty.—Dr. Furnell, of Castle Connell, Ireland, was drowned in the river near that place, in August last, by the upsetting of his boat, while on the way to visit a patient. He was a good swimmer, but became entangled in the water-weeds near the shore.

HONORS TO ROKITANSKY.—Privy Councillor Prof. Rokitansky has just received from the Emperor Don Pedro the cross of Commander of the Brazilian Order of Roses.

NEW HOSPITAL.—The new City Hospital at Worcester, Mass., is to have a frontage of 296 feet, with a centre building 60 by 62, wings 60 by 152, and three towers, —the central one 114 feet high, and the others 80. The cost of the whole is estimated in the neighborhood of $300,000.

A WORD TO ENGLISH ETHERISTS FROM DR. SQUIBB.—"It may be safely said that those who resort to it [ether] after a long use of chloroform, and acquire the little skill necessary to use it well, will have a sense of safety and satisfaction which they never knew before."

THE PRESBYTERIAN HOSPITAL in New York was dedicated on the 10th ult., with much *éclat*. Mr. James Lenox made an offer of $125,000 towards the $250,000 endowment fund desired, provided an equal amount was subscribed by others.

THE unveiling of the statue erected in Penzance (his native town) to the memory of Sir Humphry Davy took place on the 15th ult. The high standing of the Cornish chemical philosopher has at last been substantially recognized.

MR. ERASMUS WILSON, on the 11th of October, laid the foundation-stone of a house for boarders at the Medical College at Epsom, in which no restrictions as to the pupils being sons of medical men are to obtain.

NEW OBSTETRICAL JOURNAL.—*Le Mouvement Médical*, September 14, announces the commencement of a bi-weekly, the *Gazette Obstétricale*, to be edited by M. Verrier. M. Savy, of Paris, is the publisher.

DR. BUTLER, Superintendent of the Asylum for the Insane at Hartford, Conn., has resigned his office, which he had held for thirty years.

DR. ADDINELL HEWSON, of this city, has been obliged to go abroad with his wife, who has been in feeble health for several years past.

WE understand that the cause of General Meade's death was the formation of a heart-clot during an attack of pneumonia.

WE see it stated that the health of Sir Charles Locock, M.D., is in such a state as to cause grave apprehensions.

BEQUEST.—The Albany Hospital has received a legacy of $10,000 from the late William H. De Witt.

MORTALITY OF PHILADELPHIA.—The interments reported at the Health Office for the week ending Nov. 16, 1872, were 268; of which 11 were of bodies brought from the country; making the mortality in the city 257; of the whole number, 161 were of adults, and 107 of minors. Among the causes of death were:

Consumption of the Lungs	47
Other Diseases of the Respiratory Organs	43
Diseases of the Circulatory Apparatus	11
Diseases of the Brain and Nervous System	38
Diseases of the Digestive Apparatus	12
Zymotic Diseases	14
Typhoid Fever	8
Cholera Infantum	2
Casualties	17
Murder	1
Suicide	1
Debility (including "Inanition" and "Marasmus")	26
Still-born	11
Old Age	11

THE meteorological record kept at the Pennsylvania Hospital was as follows:

	THERMOMETER. Max.	Min.	BAROMETER. (2 P.M.)
Nov. 10	50.0°	38.0°	30.32 in.
" 11	57.0	40.0	30.31 in. (Rain.)
" 12	59.5	53.0	29.93 in. (Rain.)
" 13	58.0	41.0	30.25 in. (Cloudy.)
" 14	53.5	46.0	29.90 in. (Cloudy.)
" 15	39.5	31.5	30.10 in.
" 16	45.0	31.5	30.19 in. (Snow.)

OFFICIAL LIST

OF CHANGES OF STATIONS AND DUTIES OF OFFICERS OF THE MEDICAL DEPARTMENT U. S. ARMY, FROM OCTOBER 6, 1872, TO NOVEMBER 9, 1872, INCLUSIVE.

MILHAU, J. J., SURGEON.—Granted leave of absence for thirty days, with permission to leave the limits of the Department. S. O. 230, Department of the South, Oct. 6, 1872.

DE WITT, CALVIN, ASSISTANT-SURGEON.—To report to Major John C. Tidball, 2d Artillery, to accompany his command as far as Raleigh, N.C., via Omaha, Nebraska; on completion of this duty, to return to San Francisco, and report to the Medical Director, Department of California. S. O. 197, Military Division of the Pacific, Oct. 25, 1872.

RANDOLPH, JOHN F., SURGEON.—To report in person to the Commanding General Department of the Platte, for assignment to duty. S. O. 269, War Department, A. G. O., Oct. 29, 1872.

DE GRAW, C. S., ASSISTANT-SURGEON.—Assigned to duty as Post-Surgeon at Fort Davis, Texas. S. O. 195, Department of Texas, Oct. 31, 1872.

KINSMAN, J. H., ASSISTANT-SURGEON.—Assigned to duty as Post-Surgeon at Fort Ellis, Montana Territory. S. O. 216, Department of Dakota, Oct. 31, 1872.

TILTON, H. R., ASSISTANT-SURGEON.—Granted leave of absence for thirty days. S. O. 213, Department of the East, Nov. 2, 1872.

MUNN, C. E., ASSISTANT-SURGEON.—Granted leave of absence for thirty days, with permission to apply for an extension of thirty days. S. O. 276, War Department, A. G. O., Nov. 2, 1872.

BILL, J. H., SURGEON.—Relieved from duty in Department of the Columbia, to proceed to New York City, and, on his arrival there, report by letter to the Surgeon-General. S. O. 281, War Department, A. G. O., Nov. 7, 1872.

HUBBARD, VAN BUREN, ASSISTANT-SURGEON.—Relieved from operation of S. O. 19, c. s., War Department, and to report by letter to the Commanding Officer, Department of the Gulf, for assignment to duty. S. O. 281, War Department, A. G. O., Nov. 7, 1872.

VICKERY, R. S., ASSISTANT-SURGEON.—To accompany detachment of 1st Artillery, leaving New York City on 9th inst., to Barrancas, Florida, and, on arrival there, to report to the Commanding Officer, Department of the Gulf, for assignment. Telegraphic order of 5th inst. from A. G. O.; confirmed by S. O. 281, War Department, A. G. O., Nov. 7, 1872.

GODDARD, C. E., SURGEON.—Assigned to duty as Post-Surgeon at Fort Hamilton, N. Y. Harbor. S. O. 129, Department of the East, Nov. 9, 1872.

SATURDAY, NOVEMBER 30, 1872.

ORIGINAL LECTURES.

CLINICAL LECTURES

ON PROLAPSE OF THE WOMB.

BY WILLIAM GOODELL, M.D.,

Physician-in-Charge of the Preston Retreat; Clinical Lecturer on the Diseases of Women and Children in the University of Pennsylvania.

LECTURE II.

WE pass now to the third form of prolapse of the womb,—that from (the so-called) *hypertrophic elongation of the supra-vaginal portion of the cervix.* But to understand it fully we must first furbish up our knowledge of the anatomy of the parts involved.

The womb is described as having a body, or corpus, and a neck, or cervix. The latter is divided into two unequal parts,—the glandular portion, which is comprised between the os externum and the os internum, and the non-glandular portion, or isthmus of the cervix, viz., that intermediate and contracted portion which unites the fusiform and glandular cavity of the neck to the triangular cavity of the body. The length of the healthy multiparous womb is about three inches. Of this the glandular portion of the cervix measures approximately one inch and a quarter, the isthmus one-half of an inch, and the body one inch and a quarter.

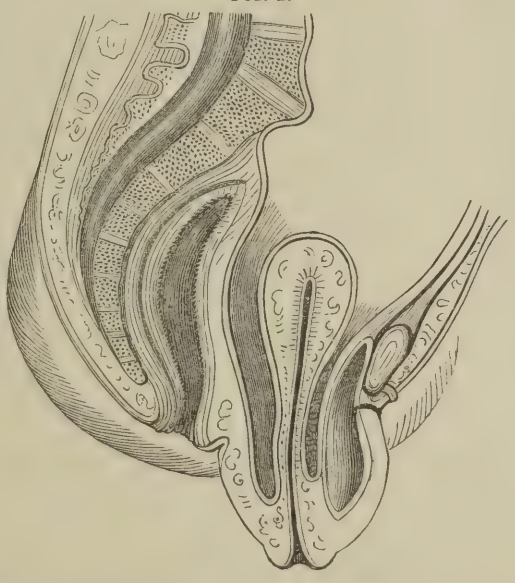
By the terminal fibres of the vagina, which gird it at the middle third of its glandular portion, the cervix uteri is still further divided into the infra-vaginal and the supra-vaginal portion. The free extremity corresponds to the infra-vaginal portion: about this there is no dispute. But the supra-vaginal portion of the cervix, as commonly described, is that portion of it which lies between the apparent vaginal insertion and the body of the womb. It therefore is made to include the upper third of the glandular portion of the cervix, and the whole of the non-glandular portion,—viz., the isthmus; and these two portions are generally believed to be the seat of the elongation. But this strikes me as an error, founded upon a misconception of the true extent of the supra-vaginal portion of the cervix.

Anatomically, this portion of the cervix is limited to the isthmus, and is therefore above the glandular portion. For, although the bulk of the vaginal fibres lie below the internal os, and the surface of attachment is to the eye a narrow one, yet in reality it is a broad one, covering two-thirds of the cervix, and reaching up to the os internum, where its fibres end.

Again, the base of the bladder rests upon the anterior wall of the vagina, to which it is fused by connective tissue, and it is also firmly attached to the anterior aspect of the cervix as far up as the os internum. These fibres of attachment are so closely blended with those of the vagina, that the supra-vesical portion of the cervix is practically the supra-vaginal portion, and each, therefore, lies above the os internum, and consequently above the glandular portion of the cervix. I beg you to bear these anatomical facts in mind, because on them hinge the arguments by which I hope to prove to you that the elongation found in this affection is not essentially hypertrophic; and that it is not the commonly accepted supra-vaginal portion of the cervix which is principally lengthened out, but rather the supra-glandular portion of the womb, that is to say, the isthmus and the lower portion of the corpus. But, until this has been proved to you, I shall adhere to the conventional name and attributes of this affection, although they assume it to be an hypertrophy, and its seat in the supra-vaginal cervix.

By studying this diagram it will be plain to you

FIG. 2.



that a wide difference subsists between a prolapse of the whole womb by descent, and a prolapse from an elongation of the supra-vaginal portion of the cervix. The term prolapse, as applied to this kind of elongation, as well as to that of the infra-vaginal portion, is a misnomer; because, although in both the cervix may protrude from the vulva, it does so more through elongation than from displacement. There is, in other words, a descent of the cervix,—a prolapse of the cervix, if you please, without necessarily any sinking down whatever of the fundus. Indeed, these two affections would seem to imply such a firmness in the suspensory ligaments as should, at first, keep the fundus from sagging down in the pelvis. This brings us at once upon debatable ground; but we will prudently keep neutral, and not display our colors until the "situation" has been studied out. But for that matter, to tell you the truth, I have hardly yet been able fully to make up my mind and range myself under any one banner. The question of hypertrophic elongation is to the gynæcologist what the late Schleswig-Holstein question was to European diplomatists. "I and another man," said Lord Palmerston, "were the only two persons in Europe who understood

this question. He is dead, and I—well, I have forgotten all I knew about it."

The woman who has just been brought in is greatly afflicted by the disease which we are discussing. In order to spare her feelings, and to give us ample facilities for studying the condition of her reproductive organs, I have had her completely etherized. She is forty-one years old, but hardship and over-work make her look much older. Her family consists of an invalid husband and six children, all of whom she supports by taking in washing. Five of her labors presented no difficulties; but the sixth, four years ago, proved tedious from the size of the child's head, and ended with the mishap of a torn perineum. She never afterwards felt strong; had lingering lochia, more or less leucorrhœa, "bearing-down feelings," and other uterine symptoms, which she attributed to her getting up and working too soon. Three years ago her urine began to scald her. The pain, at first bearable, daily grew worse, and soon became so acute that she now empties her bladder as seldom as possible. Not long after this, a tumor began slowly to protrude more and more from the vulva. It was and still is reducible, but its reduction, which at first gave her no pain, causes her so much suffering that she has dispensed with a perineal pad, long worn to keep it within the vagina. Her condition is truly a sad one: micturition and defecation are both difficult and painful; the former exceedingly so. The urine, no longer voided in a jet, dribbles over her person and excoriates it. She straddles when walking, complains bitterly of the constant dragging weight of the tumor, and now, in the prime of life, finds herself too crippled to work; while, to add to her afflictions, both she and her eldest daughter are confirmed epileptics.

This, in brief, is the history of the case; but it leads to no diagnosis more positive than a shrewd guess. Certainty can be gained only by a careful examination of the diseased parts. As I separate the thighs, you see protruding from the vulva this large boggy tumor, shaped like a truncated cone. Its apex is evidently occupied by the vaginal portion of the cervix, which is clubbed, snout-like, and apparently much hypertrophied, but not elongated. Upon a closer inspection, this condition of the cervix seems to be owing not so much to a hyperplasia of its parenchyma, as to a thickening of its mucous investment, to the gaping open of a lacerated os, to the turgid papillæ of the cervical canal, and to the exuberant growth of its submucous layer. There is an eversion of the lips, and a partial rolling out of the *arbor vitæ*. It constitutes, in fact, an imperfect attempt at an inversion of the glandular portion of the cervix, in which the loose mucous lining has participated to an extent greater than that of the more resisting parenchyma.

See this opening at the apex; it is not the external os, as you may think, but a portion of the canal much higher up. Here, about an inch from it, and describing an irregular margin around it, is the os externum. Let me prove this to you. I stroke down and pull together the jagged and widely divergent lips of the os externum, and now the cervix is somewhat elongated, reduced one-half in thickness, and made to look like a bishop's mitre. The vagina is wholly inverted; whilst partly upon it and partly upon the cervix are two large ulcers, one of them covered by a croupy exudation. These, I think, are attributable to friction from her clothing, to exposure to the air, and to the action of the dribbling urine.

Permit me to digress for a moment, in order to point out to you the difference in the behavior of true and false mucous membrane when exposed to atmospheric action. Under such circumstances, true mucous membrane—viz., that covered by conoidal epithelium—does not materially alter in structure. For instance: the lining membrane of the bladder in exstrophy; of the rectum in prolapse; of those air-tubes, the bronchia, does not become cuticular. Look at the folds and arborescent plicæ of this everted portion of the cervical canal; they are swollen and angry-looking, but not at all changed in structure. Contrast with them the squamous epithelium which lines the vagina and covers the vaginal portion of the cervix. It has become so derm-like as to resemble the pink skin of a new-born infant. There is here no sharp margin defining the limits of these two forms of mucous membrane, but the one shades into the other by transitional, or spheroidal, epithelium. It is this change of structure in the false mucous covering of the cervix that makes the dilating stage of labor so tedious in wombs that are or have been prolapsed. In such cases multiple incisions of the os have often been resorted to.

To determine whether the bladder is prolapsed, or whether it enters into the tumor as one of its constituents, I shall now pass in the uterine sound. As I expose the meatus, which is much sunken, a cluster of vascular growths comes into view. These are nothing more than hypertrophied mucous papillæ, and yet they are exquisitely sensitive. Their presence explains, in part, our patient's painful micturition; for, small as they are, from the irritation excited by friction and by the passage of the urine, they give intolerable anguish. These caruncles range in size from that of a millet-seed to that of a raspberry, but the suffering caused by them bears no relation whatever to the amount of growth they have attained. Mark the unusual course which the sound takes; it passes in almost vertically, with its concavity looking downward. I can feel its tip at a point half an inch from the apex of the tumor. You can now understand why, in passing her water, our patient experiences a difficulty apart from the pain caused by the presence of the vegetations. For, since a large portion of the bladder is outside of her body, the muscles of the abdomen can no longer compress it; and, further, the urethra is curved sharply around the sub-pubic ligament, and flattened against it. Clearly, then, the bladder is prolapsed, and its two walls, together with the utero-vesical fold of the peritoneum, and the inverted vagina, form the anterior half of the tumor. But what forms the posterior half? To ascertain this, I pass my index-finger into the rectum, and with my thumb push up the posterior wall of the inverted vagina. By this double touch I learn that a

small pouch of the anterior wall of the rectum (a rectocele) has been diverted into the protruded mass. This explains her difficulty in defecation. Again; you know that Douglas's pouch is so closely fused to the posterior *cul-de-sac* of the vagina that the descent of the latter necessarily involves that of the former. Hence we may unhesitatingly include this peritoneal fold among the constituents of the tumor.

(To be continued.)

ORIGINAL COMMUNICATIONS.

PRACTICAL HISTOLOGY IN VIENNA.

A COMMUNICATION TO THE BIOLOGICAL AND MICROSCOPICAL SECTION OF THE ACADEMY OF NATURAL SCIENCES OF PHILADELPHIA.

BY JAMES TYSON, M.D.

AT the request of the secretary, I have consented to give a verbal account of a recent brief experience in the laboratory of Prof. Stricker of Vienna, though conscious that I shall necessarily state some facts which are elementary, and familiar to many members of the section.

I am confident, in the first place, that those who are not familiar with the so-called "laboratories" abroad will be disappointed with the simplicity of their appointments in the majority of instances. Thus, the laboratory of Prof. Stricker consists of two moderate-sized apartments, one about thirty feet by fifteen feet, and the second half as large, with a still smaller private room, occupied by the Professor himself. In the largest room is a plain pine table, painted black, capable of accommodating eight or probably ten gentlemen with their microscopes. In the centre of this room, also, is a table like an ordinary dissecting-table, on which investigations are made upon animals, generally rabbits and dogs, secured in position by means of Czermak's "rabbit-holder." This consists of a rectangular piece of board perforated at the sides and one end by holes, through which cords can be conveniently passed. At the remaining end a semicircular piece is sawed out, producing a concavity which will conveniently receive the back of the neck of the animal, in the mouth of which is placed the well-known "bit" of Czermak, which effectually protects the experimenter from the bite of the animal. The perforated board and bit are adapted in size to that of the animal upon which the investigation is to be made, those used for large dogs being, of course, much larger than those used for rabbits. The animals experimented upon are generally curarized, the curare being kept in concentrated solution in glycerin, diluted for use, and introduced hypodermically. In this room is also a kymographion, protected by a covering of green baize, and made in the laboratory by one of Professor Stricker's "diener," who did it in something less than a year. In addition to these are closets along the wall, for chemicals, solutions, etc., microscopes and other apparatus when not in use. The smaller room contains a similar table for microscopic work, and is generally occupied by the assistants, while the pupils work at the table in the larger room.

From this description, which may be considered as applicable to a number of laboratories which I visited, it will be seen that the word *laboratory* is properly used to indicate a work-room, or place to work in, quite consistently with the etymological and primitive meaning of the term. The supply of material appeared to be abundant, as to frogs and smaller animals; but I have known as much as ten florins (about five do lars, and really equivalent to ten dollars with us) to be paid for a large dog.

Quite an institution in the laboratory are the two "diener," or servants, one of whom is a good mechanic and makes much of the apparatus used in the laboratory; but the deliberation with which he does it is something remarkable, especially to Americans. I am sorry to be able to say nothing more favorable of "Louis," the second "diener," than that he is an adept at fastening dogs, and at omitting to do anything which may be requested of him.

Although furnished with accurate information as to the situation of the Pathological Institute, I wandered for some time among the various quadrangles and courts of the great General Hospital before I succeeded in finding the laboratory. My knock at the door was answered by a lusty "*Herein.*" Entering, I found several gentlemen in shirt-sleeves working over microscopes, one of whom responded, in very good English, to my inquiry for Prof. Stricker, to the effect that he was the person. I found him much younger, and very much less a "bear," than I had expected; apparently less than forty years of age, of medium stature, wearing no whiskers, except a moderate mustache, and dressing neatly. He treated me most courteously, and, on learning the object of my visit, very promptly effected an arrangement by which I was to work a certain number of hours daily with one of his assistants, Dr. Spina.

The microscopes used in the laboratory, and in Vienna generally, are Hartnack's, also Hartnack's lenses; and I saw no others there. The highest power used was an immersion No. 10; but this was frequently called into requisition. The great size and the reputed conveniences of our own and the English stands are not at all appreciated, and the beautiful stand of one of our best American makers, brought to Vienna by an American surgeon, was a source of considerable merriment to those who saw it, who regarded it as a sort of machine. The microscope is altogether used in the vertical position; and the precaution so much insisted upon among us, of keeping the unemployed eye open, was considered, at least by those who taught me, absurd advice, and by many had never been heard of. It may be added that the microscopes used by the assistants and students are the property of the Pathological Institute.

Having finished the subjects of blood and epithelium in the laboratory of the Brown Institution in London under the direction of Klein, we passed directly to the study of

CONNECTIVE TISSUE.—For this purpose a small portion of the mesentery of a living frog is placed upon a slide in a drop of serum or one-half per cent.

solution of chloride of sodium, and covered with a thin glass cover. Five forms of cells are met with in connective tissue.

1. The *wandering cell*, exhibiting its peculiar amœboid movement resulting in a change of shape, to which is added, also, a change of position. This connective-tissue corpuscle assumes a permanently round form on the addition of water, when it may be said to be dead. These, in some instances at least, are probably white blood-corpuscles which have migrated through the walls of blood-vessels into the connective tissue.

2. The well-known, coarsely granulated (grob-granulirt) *spindle-shaped* connective-tissue corpuscle, provided with an elliptical nucleus.

3. The *round, finely granulated* (fein-granulirt) connective-tissue cell, which exhibits no movement, or at least a very slow one, and differs only from the dead amœboid cell in its larger size. These generally have an oval nucleus, or, according to Rollett, their contents may appear to be accumulated at one point around a body resembling a nucleus; according to this observer, also, they give off radiated prolongations which often join. Between the spindle cell and the round cell are intermediate shapes.

The same study may be made in the connective tissue derived from the fresh muscle of the thigh or leg of the frog or rabbit; but the cells are less numerous.

4. In the connective tissue of the muscles of mammals, *cylindrical* (walzenförmig) cells are sometimes found, containing an elliptical nucleus.

5. Finally, *pigment-cells* are also found in connective tissue, abundantly in amphibia and fishes, but to a limited degree only in man (iris, choroid, and innermost layers of the sclerotic). These are usually provided with a central nucleus, often obscured, and also exhibit movements, which are, however, exceedingly slow in adult batrachians, but more rapid in their embryos.

Rollett, in Stricker's Histology (New Syd. Soc. translation, p. 57), describes other finely granular cells "which are for the most part more delicate and pale, and frequently exhibit fine radiating strongly refracted striæ of greenish tint. These easily overlooked, delicate, and proportionately large structures may be best distinguished by their very distinct, large, vesicular nuclei." I have had no opportunity of recognizing these cells as special forms.

The addition of very dilute acetic acid, so dilute as to be just appreciably sour to the taste, causes an increased granular appearance in these cells. A stronger solution, say .20, causes a more distinct exhibition of the nuclei, which in the case of the migratory cells are round and smaller, and frequently exceed one in number, while the nuclei of the other connective-tissue cells are *oval* in form and larger in size. The addition of still stronger acetic acid produces shrivelling in the cells, a formation of folds, and extrusion of the nucleus in the case of the wandering cells.

One or more of these cells are met in *two principal varieties* of connective tissue: 1. Trabecular tissue (Balkennetz), adenoid tissue of His, embryonal tissue. 2. Fibrillar connective tissue.

1. The *trabecular connective* tissues are generally characterized by the fact that they do not yield gelatine on boiling. They form net-works of which the trabeculæ were primarily produced by the union of radiating processes of cells. These may preserve their cellular character in retaining the nuclei of the cells, producing thus a nuclear trabecular tissue, or the trabeculæ may so acquire a fibrous constitution as to be undistinguishable from bundles of the fibrillar variety of connective tissue. This variety of connective tissue may occur in independent masses, as in the so-called mucous tissue of the umbilical cord, or it may serve as a means of support, or investment of protection, for fibrillar connective tissue, or vascular (capillary) tissue, or organs, as in the lymph-glands and similar structures, Peyerian and solitary glands, the mucous membrane of the intestines, tonsils and follicles of the tongue, the conjunctiva and its trachoma glands, and the nasal portion of the pharynx. In these latter instances the meshes are filled with the peculiar lymphoid (amœboid) cells described. They are also traversed by blood-vessels, and unite also upon the external surface of the blood-vessels to form the tunica adventitia capillaris of His.

It is this tissue which constitutes the neuroglia of Virchow, the delicate supporting connective tissue of the eye and nervous centres. It also occurs as a constituent of certain pathological new formations. This form of connective tissue is best demonstrated, according to the method of His, by carefully brushing thin sections of the hardened tissue with a camel's-hair brush, by means of which the lymphoid cells are removed, and a delicate net-work is left behind, composed of trabeculæ enclosing round or polygonal spaces: these trabeculæ are sometimes distinctly seen to be composed of nucleated cells or to exhibit nuclei, or, in consequence of age, to have lost all cellular characters.

2. *Fibrillar Connective Tissue.*—Between the trabecular connective tissue or "Balkennetz" and the fibrillar form are intermediate forms; but the great bulk of the connective tissue of the higher animals, at least, is made up of the fibrillar variety.

This—to which alone the term connective tissue was formerly applied—is transformed into gelatine on boiling, and is characterized by the well-known fibrous structure implied in the term fibrillar. The cellular elements are those already described, and can only be satisfactorily studied in the young formation of this tissue when quite fresh.

The toughness or close adhesion of many forms of this connective tissue, as in the cornea, sclerotica, tendons, fascia, and even subcutaneous tissue, is well known. It is often so great as to make it impossible to isolate the fibrillæ composing it, without the use of reagents. One of the best of these is *simple lime-water*. A piece of sclerotica or subcutaneous tissue, for example, is thrown into lime-water and allowed to remain for twenty-four hours. At the end of this time a small piece is taken out and frayed with needles. If it stubbornly resists the dissection, it is replaced in the lime-water for

another twenty-four hours, when the dissection is repeated. If necessary, the maceration may be continued even longer, when the dissection may be made with surprising facility, and beautiful preparations may be made in which the separate fibrillæ may be clearly displayed. The sclerotic and cornea of the rabbit and the subcutaneous connective tissue from the dog—which is very tough and difficult to fray out—were thus successfully manipulated.

A similar agent is baryta-water, acting more promptly than lime-water and accomplishing the same results in from four to six hours.

A third reagent, which acts similarly, though not so rapidly as the lime-water, is a solution of *bichromate of potash*, of a dark straw-yellow color. The maceration may be continued two or three days, according to the firmness of the tissue, and the solution should be renewed. The fibrillæ are thus rendered easily isolable. The use of this solution is attended by a yellow coloration of the fibrillæ, which may or may not be desirable. This solution was used successfully in the treatment of the adventitia of blood-vessels and in the case of tendons.

The rationale of these processes is not precisely known; though it is usually said that the lime-water and bichromate of potash dissolve a species of cement (Kittsubstanz) by which the fibrillæ are believed to be held together.

Very interesting are the effects of acetic acid and boiling water upon the fibrillar connective tissue. Acetic acid of almost any strength beyond .20, it is well known, removes completely the fibrillar appearance of this form of tissue, rendering it homogeneous, and increasing the width of the bundles, while the cellular element and the cord-like fibres of yellow elastic tissue are rendered more distinctly visible. On the other hand, the addition of a little weak solution of ammonia promptly restores the structural characters.

Again, a piece of subcutaneous connective tissue was boiled in water in a test-tube for five or ten minutes. There resulted the same absence of fibrillar appearance, with increased width of the bundles, and constrictions at certain points where the spirally *surrounding* fibrillæ still remain, not permitting the swelling to take place in these situations. Longer boiling dissolves or causes the disappearance of these surrounding fibres also, and if continued still longer causes a solution of the entire mass into gelatine. Tendon was also similarly treated, and with the same results. For these purposes the hot-water stage of Stricker may be used to great advantage.

The staining of connective tissue was attained by two principal staining solutions, *carmine* and *chloride of gold.*

Carmine staining was accomplished by making an ammoniacal solution of carmine, without particular regard to strength, and diluting by water. The tissue was placed in a small quantity of this, and examined from time to time, to determine the degree of staining. When the proper time of immersion for a given fragment was determined, others of the same kind and size were immersed for a corresponding period. In all instances an intensity or vividness was secured by further treating the stained tissue by a very weak solution of acetic acid, of a strength just sufficient to allow the acid to be tasted. This staining is not restricted to any one element of the tissue, but is general, the cells being more deeply tinted than the fibrillæ.

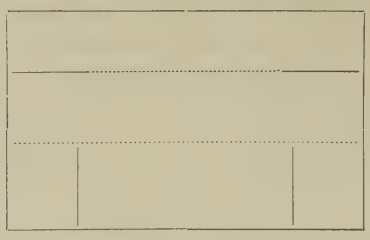
Staining connective tissue with *chloride of gold* has for its object more particularly the demonstration of the cells of the connective tissue, and was thus practised in the case of delicate connective tissue. A piece of the mesentery of a frog is carefully cut out and stretched by means of pins over a fenestra cut in cork. Thus prepared, it is placed in a one-half per cent. solution of chloride of gold for ten minutes, after which it is removed to distilled water slightly acidulated by acetic acid, where it is allowed to remain twenty-four hours, in order that the gold may be reduced and the cells stained. The preparation when taken from the acid should be of a uniformly violet color; it will also be somewhat hardened. It is then examined in glycerin. The different forms of connective-tissue corpuscles should be noted, and care should be taken not to mistake for them the nuclei of clumps of the red corpuscles of the frog, which are apt to be encountered in consequence of section of a blood-vessel.

The period of immersion cannot be positively stated: experiment must determine the exact time. Ten minutes is perhaps an average: larger preparations require longer, the more delicate a shorter time.

So far, however, as my own limited experience went, I am not disposed to attribute much utility to the gold staining of connective tissue. The cells only are stained, and that somewhat faintly, and the preparations cannot be mounted to keep any length of time, while the vividness and permanence of carmine stainings, when mounted in glycerin or slightly acid glycerin, are well known.

Making Sections of Tendon and other Tissues.—The imbedding process was always employed; the substance made use of for the purpose being white wax reduced in consistency by oil, the two being melted together. The consistency to be obtained is one approaching that of the tissue to be cut after hardening, while the quantities employed to attain it must be influenced by temperature, the season of the year, etc. The preparation is always previously hardened in alcohol or chromic acid, and in the case of tendon it is sometimes dried, when indeed it may be cut without imbedding, though the change undergone by a specimen thus treated is manifestly great. The process employed is very simple. A little box is made of moderately stiff white paper, and adapted in size to the preparation to be cut. The box is made in the following simple manner. A rectangular piece of paper is folded as indicated by the dotted lines and cut as shown by the plain lines in the diagram; this permits the corners to be turned up and about each other, so that, being pasted in this position, a neat box is formed. The preparation is then taken from the fluid in which it was immersed (the excess being allowed to evaporate, or removed by bibulous paper), and perforated towards one end by a pin, which is then thrust into the floor of the box in such a way that the preparation occupies a central

position, so that the molten matter may readily flow around it. The mixture of wax and oil is then



melted over a spirit-lamp, and allowed to cool until a slight film begins to appear at the edges. It is then poured rapidly around the preparation and allowed to cool. If it is desired that the cooling take place rapidly, it may be placed in water; but, if possible, it should be allowed to cool gradually. After the mass is cool, the paper is stripped off. We then have a rectangular prism, of convenient size to hold between the fingers. This is cut with an ordinary knife until the preparation is reached, when sections are made with a broad, flat knife mounted like a razor, which is much used in Vienna, the imbedded tissue wrapped in a towel being held in one hand and the knife in the other. No precise directions can be given as to the mode of making the sections: experience alone can teach this. It must not be omitted, however, that the knife and upper surface of the preparation should be wetted in each case with alcohol or water, according to the previous immersion. So also the section is floated off the knife in alcohol or water, according to its previous treatment. It may likewise be stated that it is not necessary to cut entirely through the imbedding substance, but that it is better to start the knife just beyond the edge of the specimen to be cut.

After the sections are made, they may be stained in chloride of gold or carmine or other staining fluid, in the manner described. Or if the tendon is a delicate one, as certain almost thread-like tendons of the frog, it may be stained before the sections are made.

(To be continued.)

ON THE EFFECTS OF THE BROMIDES IN EPILEPSY, WITH SPECIAL REFERENCE TO THE BROMIDE OF POTASSIUM.

BY M. GONZALES ECHEVERRIA, M.D.,

Resident Physician to the New York City Asylum for the Insane, Ward's Island, N.Y.; Consulting Physician to the New York Hospital for Epileptics and Paralytics, etc. etc.

(Continued from page 118.)

I HAVE observed the eruption of the skin in one hundred and twenty-one males and one hundred and sixty-two females. It displays itself in scattered pustules, and in some instances as a rash or diffuse elevation of the skin, over the chest and limbs, this being particularly noticeable in females and children. I have met with the bromide eruption at all seasons of the year; though Voisin says that it only occurs in winter. In twenty-eight males and in thirty-four females of the above cases, the eruption was of a very slight character, thus modified by the use of arsenic, which had not been employed in the other instances. I have seen the eruption crop out twenty-four hours after the giving of the bromide, but it usually appears from three to seven days after, and is ordinarily painless. It seems as though females and children were more liable to the eruption than adult males. In many instances there is instead of the pustules, and without any previous reddening or swelling, a peculiar discoloration of the skin, a brownish hue, more conspicuous on the forehead or neck; but, as just said, the eruption is oftener of a papular nature, breaking out first in the face, chest, and back, and very much resembling acne. The papulæ may break out again in a confluent form in the elbows, dorsal region of the hands, knees, or lower limbs, determining an extensive and painful subcutaneous suppuration, as I have observed in three males and five females. This complication ceases on the discontinuance of the bromide. The most extensive cutaneous eruption I have met with was in two females: one had an ulceration over the whole posterior face of the right forearm, and the other over the right knee; in both instances the eruption was painful, but subsided rapidly on suspending the bromide. The scar left by the pustule has a bluish, smooth aspect, or is sometimes of a dark-brown color. It is not permanent, though the scar of confluent pustules may persist for several months. I have never noticed the same portion of the skin to be twice affected by confluent pustules. In two males there was inflammation, or rather a painless swelling, of the parotid and maxillary glands, along with large furuncles in the same region. In another male, a large eczematous eruption, which lasted only a few days, broke out in the left side of the face and left forearm. These three last patients were epileptic insane.

I do not think that the existence of the eruption bears any relation to the effects of the bromide on epilepsy. Its occurrence is far from constant, whereas many epileptics I have attended have been relieved of their attacks, and indeed so far cured, without having ever exhibited any eruption; whilst this latter has been present in its worst form in epileptics who have remained unbenefited by the bromide. I have already referred to the association of the arseniate of potash with the bromide to avoid the occurrence of the bromide eruption. We, however, fall short of this result when arsenic has not been employed from the beginning, or if the eruption be not previously arrested on a discontinuance of the bromide, or if alkaline baths are not administered along with the two salts, in cases where the predisposition to cutaneous trouble is manifest in any high or persistent degree.

I look upon anæsthesia of the skin and mucous membranes as one of the most constant effects of the bromide of potassium. I find anæsthesia of the skin distinctly recorded in 216 cases: 86 males, 130 females. The phenomenon was general among 50 of the first and 78 of the latter, loss of sensibility being more evident in the lower limbs in the remaining cases, thus accounting for the totter-

ing gait then observed. I am satisfied that the ataxic symptoms attending the administration of large doses of bromide of potassium are mainly due to the loss of tactile sensibility. This latter has appeared to be more or less impaired in every one of the cases, but not the perception of heat, for such epileptics have at once objected to and complained of any hot application to their skin, no less alive to painful impressions. Nevertheless, in 23 males and 42 females the perception of temperature was unmistakably lost, and in three males there was, besides, complete analgesia superinduced by the bromide of potassium. One of these epileptics, admitted into this asylum in the last stage of dementia, had been taking for five weeks half an ounce of the anti-epileptic mixture, containing thirty grains of bromide of potassium, three times a day. The frequency and severity of the fits had decreased, and he became less stupid, when one morning he unconsciously and most severely burned his toes by keeping his feet over the steam-pipe of the radiator in the ward, until he was discovered and removed therefrom by one of the attendants. Furthermore, I have remarked that the insertion of a seton, or cauterization with a red-hot iron, in the back of the neck, has caused very little pain to epileptics under a regular course of treatment with the bromide, and who in the beginning were very sensitive to such operations.

Reflex reactions are lessened under the influence of the bromide. The tactile sensibility of the pharynx has been lost and deglutition impeded in every case of complete bromism, all liquids passing then through the nose or into the larynx. This, however, I repeat, has been an accident of bromism, whereas deglutition has continued unimpeded in every instance until the extreme physiological effects of the salt have been induced. The sensibility of the pharynx is, indeed, blunted or considerably diminished by the bromide, and more so in the case of children. A curious illustration of this fact was exhibited by a girl, ten years old, who had become epileptic after scarlatina, and who, while taking ninety grains of bromide daily, had a fish-bone imbedded in the right pillar of the fauces, no distress following for four days, at which time the parents became alarmed at the fetidity of her breath and salivation, which disappeared upon the removal of the fish-bone from the palate. One circumstance which deceives us very materially on examining the state of anæsthesia of the pharynx, in reference to the effects of the bromide of potassium thereon, is, whether the patient watches or not the application of the instrument or object employed to test the pharynx's feeling. Laborde has pointed out this cause of error, and I may add that the same thing operates no less actively when we inquire generally into the sensibility of the skin, for there was not one case where tactile perception did not become more acute after the patient had seen the instrument employed to ascertain his degree of sensibility.

Loss of taste has been frequently complained of in the beginning of the use of the bromide, but has not persisted, to my knowledge, in any case. A male epileptic, subject to fits attended with furious mania, was directed, upon admission into the asylum, to take thirty grains of bromide of potassium three times a day; thereupon he lost all sense of taste, and became very much distressed. He could not distinguish the taste of tobacco or salt from pepper, and his food, when chewed, conveyed to him the sensation of cotton, being entirely tasteless. Deglutition continued unimpaired, as did also the feeling of temperature, and his breath did not become foul. Tactile sensibility of the tongue and throat did not appear materially affected; titillation of the uvula would make him gag, until the taste gradually returned in the course of six days.

The sense of smell may become equally affected by the bromide of potassium, not from the hypersecretion from the Schneiderian membrane, but from the diminished sensibility of the nerve. I have observed such substances as tobacco, snuff, ammonia, etc. to excite no sneezing, and in the epileptic just cited the sense of smell also disappeared, to return long after the recovery of taste. Seven males and eleven females exhibited loss of smell upon the use of the bromide of potassium. It is not uncommon to remark in inveterate epileptics an injection of the conjunctiva, a real conjunctivitis with thick discharge from the palpebral glands, similar to that frequently accompanying other forms of insanity or noticed where the unsoundness of mind has a larvated and undefined character. The bromide of potassium may originate, not seldom, a similar congestion of the conjunctiva, with muco-purulent discharge from the eyelids, the eye becoming very red and sensitive to light. This effect is more particularly met with among epileptics in a state of general paralysis, or melancholia, as well as among those subject to frequent meningitic congestion, in all of whom the bromide may arrest the repetition of fits, but seems to be without any beneficial influence over the progressive mental derangement.

Of the rarer phenomena attending the use of the bromide of potassium in epilepsy, I may say that diarrhœa has been recorded in five of the epileptics here considered, three adult females and two male children. The phenomenon did not persist, and passed away after a few weeks, without any special treatment. In one female the salt in drachm doses would induce nausea and vomiting, and in an epileptic soldier, at the United States Central Park Hospital, fifteen or twenty grains of bromide of potassium would always produce vomiting. He had become epileptic from the effects of a gunshot wound of the skull. Another male epileptic, insane, while under treatment, was twice seized with icterus, without any positive indication, however, that it was caused by the bromide. He died afterwards from meningitis, and two large biliary calculi were found in the gall-bladder.

Fourteen epileptics—five males and nine females—complained of diplopia while under the use of the bromide, but among a larger number there was permanent strabismus wherever the full physiological effects of the bromide were induced. I have examined with the ophthalmoscope, on different occasions, the retina of epileptics in a state of bro-

mism, and I have so far been able to make out a pretty uniform change in most of the cases. In two females there was a brighter redness and pulsation of the veins upon the disk, which was not noticed before or after the supervention of bromism. A hazy condition of the disk is recorded in five cases,—three males and two females; whereas the memoranda of thirty-eight more cases—eleven males and twenty-seven females—show that the retina was in a state of congestion with an increased reddish tint of the disk, continuing along with the bromism and for one or two days after. These observations agree with those of Nicol and Mossop, who have concluded, from their experiments on the action of certain neurotics on the cerebral circulation, that bromide of potassium produces congestion of the brain (*British and Foreign Medico-Chirurgical Review*, July, 1872). I cannot, consequently, assent to Laborde's statement,—that no alteration takes place in the optic nerve of bromized individuals (*Archives de Physiologie*, May, 1868).

Irritability of temper has frequently attended the administration of the bromide of potassium, as a transient phenomenon in the first few days. In some instances of epilepsy without insanity, the bromide has superinduced mania. In one female, as low a dose as ten grains of the bromide would set her wild, with hallucinations of hearing, and suicidal mania: she afterwards could take, however, twenty grains of the salt associated with narcotics, thrice daily, favorably and without the above symptoms. Any larger quantity than thirty grains would also produce suicidal mania in two other females. Another female, again, would become maniacal on twenty grains of bromide repeatedly taken, while two of her companions were rendered, by the same amount, one melancholic, with delusions of hearing, and the other melancholic and drowsy. Among males, homicidal mania has occurred three times, eight have become melancholic, and several others have shown hallucinations of sight or hearing, upon exhibition of large doses—from thirty to forty grains—of bromide of potassium. One young man, subject to nocturnal attacks, has remained entirely free from them and from the mental excitement that they occasioned, as long as he took one drachm of bromide of potassium daily; he nevertheless was all the time melancholic, and ceased to be so on stopping the bromide, when the nocturnal attacks again recurred. I have noticed in two male and three female epileptics, not insane, under the continued daily use of from sixty to ninety grains of bromide of potassium, that without premonitory mental or physical derangement, they became amnesic. Two of the females, particularly, were quite aphasic, and not only did they forget certain words, but they also became unable to utter certain others. None of these epileptics had aphasia in relation to their fits; nay, these were checked when the aphasia was exhibited. The discontinuance of the bromide was directly followed by that of the aphasia, which returned again when treatment was resumed. Voisin mentions a similar instance of aphasia in a male epileptic subject to the continued influence of the bromide, and Professor Clarke, of Harvard University, in his recent valuable monograph on the bromide of potassium, reports the case of a lady, suffering from chronic ovarian disease, to whom he gave a continued daily dose of forty grains of bromide of potassium. After she had taken it for two weeks, she began to exchange two words for each other; and the peculiarity disappeared shortly after she discontinued the use of the bromide.

I have little to add to describe the peculiar phenomena of bromism. They are: congestion with swelling of the fauces and of the tongue, redness of the conjunctivæ, cheeks, and nose, dilatation of the pupils, congestion of the retina, dimness of sight, diplopia, thickness of speech, slowness of the pulse and respiration, decreased temperature of the skin, increased secretion of the salivary glands and kidneys; in some instances hallucinations of sight or hearing, and mania or melancholia, have shown themselves, the former of a suicidal nature. Deafness may occur in some cases, upon the swelling of the fauces extending to the Eustachian tube, but it readily disappears on discontinuance of the bromide. The anæsthesia of the skin and mucous membranes becomes very conspicuous, as also a tottering gait, with inability for steady exertion of any kind (writing, buttoning up the clothes, etc.), and, above all, an overwhelming drowsiness. I have further observed, in six males and nine females, a loss of power over the sphincters, with an unconscious passage of urine and excrement; two of the males, and four of the females, were children. The appetite to eat, and to smoke or chew tobacco, has never been completely lost, even while the patients were under large doses of bromide of potassium.

I cannot say that bromide of potassium has been observed to exert any special uniform effect on the derangement of menstruation attending epilepsy with the females under my care.

(To be concluded.)

A New Mode of Writing Prescriptions.—The *Clinic* contains an article from M. J. P. Bonsieur, proposing what he calls the "one-dose prescription plan;" namely, that the physician should simply put down on paper the dose to be given, thus:

℞ Ferri redacti, gr. j,
Quin. sulph., gr. ss,
Ext. gentianæ, gr. j. } × 12.

The apothecary will from this make up, of course, twelve doses of the prescribed quantities of each drug, in pill, powder, syrup, or whatever form the physician may write below. M. Bonsieur seems to think the menstruum might be left altogether to the apothecary; but it would be far better for the prescriber to indicate this.

The plan presents some great advantages, as, for example, in economy, but does not give any more security than the one now generally followed, since an absent-minded physician would be just as apt to write "Morph. sulph. gr. x" in place of "gr. $\frac{1}{10}$," as to write "℈j" in place of "gr. j." Constant care and attention to the matter in hand, adequate knowledge being of course presupposed, can alone prevent dangerous mistakes either in the writing of prescriptions or in the compounding of the drugs called for.

PHILADELPHIA
MEDICAL TIMES.
A WEEKLY JOURNAL OF
MEDICAL AND SURGICAL SCIENCE.

The Philadelphia Medical Times is an independent journal, devoted to no ends or interests whatever but those common to all who cultivate the science of medicine. Its columns are open to all those who wish to express their views on any subject coming within its legitimate sphere.

We invite contributions, reports of cases, notes and queries, medical news, and whatever may tend to increase the value of our pages.

All communications must bear the name of the sender (whether the name is to be published or not), and should be addressed to Editor Philadelphia Medical Times, care of the Publishers.

PUBLISHED EVERY SATURDAY BY
J. B. LIPPINCOTT & CO.,
715 *and* 717 *Market St., Philadelphia, and* 25 *Bond St., New York.*

SATURDAY, NOVEMBER 30, 1872.

EDITORIAL.

PROF. TYNDALL'S LECTURES.

THE medical as well as the general public have looked forward with much eagerness, ever since the first announcement of Prof. Tyndall's intention to visit this country, to the pleasure and instruction to be derived from his lectures. They have not been disappointed. His course here has been brilliantly successful, the hall having been crowded each evening with an appreciative and intelligent audience, who frequently applauded, as well they might, his admirable expositions of scientific matters.

His lectures remind us strongly of the works from his pen, which have made his name so familiar to the reading world on this side of the Atlantic. Clear and forcible in language, they are illustrated by striking and carefully elaborated experiments, which add tenfold to their interest. We may say, further, that Prof. Tyndall has made a not less agreeable impression upon those who have met him socially than upon those who have heard him in public. His visit to this city will long be remembered with pleasure.

DR. COHEN'S MÜTTER LECTURES.

THESE lectures are now in process of delivery, on Tuesday and Thursday evenings of each week, at the hall of the College of Physicians, and are well attended. Dr. Cohen has taken for his subject the surgery of the nares, larynx, and trachea, to which he has for a number of years devoted himself, and with which his summer lectures at the Jefferson Medical College, and the work he has recently published, have already demonstrated his familiarity. It is by courses of this kind that the legitimate objects of such bequests as that of Dr. Mütter will be most fully accomplished; and we trust the profession in this city will not be slow to manifest their appreciation of the opportunities thus afforded them.

ANOTHER NEW JOURNAL.

WITH the opening of the new year, a fresh enterprise will be undertaken by Messrs. Lippincott & Co., in the shape of a monthly journal, to be called the "Archives of Scientific and Practical Medicine." It is to be under the editorship of Dr. Brown-Séquard and Dr. E. C. Seguin,—names which carry an assurance of brilliant ability, and which will, we think, bespeak the favor and support of the profession not only in this country but abroad.

Each number will consist of about one hundred closely-printed octavo pages, mainly made up of original communications; the details of the plan, price of subscription, etc., will be found in our advertising columns.

LEADING ARTICLES.

ON THE TEACHINGS OF DR. J. MARION SIMS REGARDING THE CAUSE AND TREATMENT OF STERILITY.

BY DR. VON SCANZONI.

(Beiträge z. Geburtskunde u. Gynaekologie. Scanzoni, vol. vii. p. 109.)

THE fundamental idea of the modern surgical treatment of sterility by operations designed either to dilate or to straighten out the cervical canal, is that there always exists a mechanical obstacle to the entrance of the spermatozoon. Scanzoni earnestly protests against the acceptance of a theory based on careless observation of phenomena, and which necessitates the frequent performance of an operation which is in itself dangerous, and in some cases fatal. Opposed to the new school of gynæcologists, who regard the publication of Dr. Marion Sims's book on uterine surgery as the dawning of a new era in this hitherto neglected branch, he maintains that the want of careful histories of cases, and a certain or rather an *un*certain looseness of expression with regard to actual results, so decidedly deprive it of scientific value that its review becomes a difficult and arduous task. So far from regarding a mechanical obstacle to the entrance of the seminal fluid into the uterus as the sole cause of

sterility, he brings forward and urges the importance of the following morbid conditions, which may be, and often are, the causes which prevent conception,—viz., any functional disease of the ovary or testicle, which results in the production of a vitiated ovum or spermatozoon, or the occurrence of any one of the numerous pathological conditions which may prevent the exit of the ovum from the ovary, its reception by the Fallopian tube, and its passage into the uterus. We are, for the most part, utterly unable to diagnose the existence of any of the abnormal states which would produce such a result; and yet the possibility of conception depends on the physiological and harmonious sequence in the functional activity of these organs.

In order to prove that conception may occur in spite of the most extreme displacement, several cases are given in detail, where the introduction of the sound was rendered absolutely impossible, owing to the marked flexions of the uterus, or, as was the case in one instance, to the existence of an inguinal hernia of that organ; and yet, in all the histories given, conception repeatedly took place. While Scanzoni admits the general truth of Marion Sims's statement that the pain of dysmenorrhœa depends on a mechanical obstacle to the passage of blood from the cavity of the uterus, he still maintains that *all* cases cannot be explained in this way, and states that some of the most severe cases of uterine colic he has ever seen occurred before one drop of hemorrhage had taken place in the uterus, as he has repeatedly proved by the introduction of a sound, while the pain sometimes continued after the flow had been freely established, but not sufficiently so to take away the pressure from the over-excited nerves. So too the most intense uterine colic may be excited by the application of leeches to the cervix, even in cases where care has been taken to guard against the passage of one of them into the uterus,—an accident which some authors have availed themselves of to explain the severity of the pain.

Scanzoni then goes on to show in detail that in many cases it is simply impossible to diagnose, either by the fingers, sound, speculum, or by the aid of the sponge tent, such a contraction of the cervical canal as to justify us in regarding sterility as its *necessary* consequence, whether this contraction be due to a congenital or an acquired constriction of the os externum; the infiltration and swelling of the mucous membrane following a chronic catarrh of the organ, and a consequent development of the folds of the arbor vitæ; the presence of enlarged follicles with broad bases of attachment (the ovula Nabothi); new formations grouped together under the head of mucous polypi, which for the most part originate in these same follicles; more or less extensive fungous excrescences caused by papillary growths; spastic contraction of the os internum; the various and often-occurring forms of flexion; diffuse hyperplastic growths affecting either the entire cervix or only certain portions of it; myomatous and fibroid tumors having their seat either in or near the cervix; or to intra-mural or pedunculated growths attached to the body of the organ. In all of these conditions neither the sound nor our other aids to diagnosis enable us to exclude pregnancy, as the histories of numerous cases given by Scanzoni show.

The author deplores the incompleteness of the statistical tables in Sims's book. It is true that it is stated that the operation for the Bilateral Incision has been performed five hundred times, but in only six of these cases is it stated that the wished-for result was attained, viz., that the woman conceived. Four other cases in which conception followed the amputation of the cervix must be added to these. While Scanzoni does not doubt that Sims has other more extended statistical statements which place the operation in a more favorable light, still he says that these are the results from which we are asked to accept the operation. These ten cases are carefully analyzed and reviewed by Scanzoni, who finds that seven of the women had been pregnant before the operation,—in other words, that we have to do here with cases of *acquired* sterility, in which the prognosis is unquestionably more favorable. The fact that the operation is not without danger is then insisted upon by Scanzoni, and the members of the profession are exhorted to review calmly the evidence on which this operation rests,—the value of which cannot be denied in a few well-selected cases,—before they follow blindly the so-called new school of uterine surgery.

CORRESPONDENCE.

ANÆSTHESIA—DR. HORACE WELLS.

To the Editor of the Philadelphia Medical Times:

In a recent number of the *Times*, mention was made of a project for raising a Testimonial Fund for the benefit of the family of the late Dr. Horace Wells, and now the circular for that purpose, signed, I am surprised to see, by several of the most eminent medical men of this city, is lying before me. If, as individuals, they are desirous of testifying in this manner their approval of Dr. Wells's endeavors to discover the means of anæsthesia, nobody could reasonably object to the pro-

ceeding. If, however, this movement springs from the belief that he did actually make the discovery, then it becomes a fair subject of criticism. On this point we are left in no doubt. In the circular it is said, he was "a benefactor to the world;" "that he conferred upon it the greatest physical boon ever yet bestowed by man upon his fellows;" that he was the means of saving "tens of thousands of lives, as well as an untold amount of mental and physical anguish." Not so have we read the history of this matter, and, in the face of well-established facts, such representations can excite only a feeling of surprise and wonder.

The historical record is remarkably clear and explicit. It gives no uncertain meaning. In the autumn of 1846, several surgical operations were performed in the Massachusetts General Hospital, in Boston, without causing pain, under the influence of sulphuric ether, and thus were demonstrated, beyond a reasonable doubt, the practicability and complete success of this method of producing anæsthesia for such a purpose. From that time this great achievement became, not a matter of guessing, or of speculative belief, but a fixed fact, a veritable reality. During the twenty-five years or more that have since elapsed, the great majority of the profession, as well as the unprofessional public, have believed, even from the first, that the honor of conferring this signal blessing on mankind is due, wholly or partly, to either Dr. Jackson or Dr. Morton. Why, then, are we asked, at this late day, to reverse this judgment, and bestow the honor on one who failed to realize the idea which he and others had entertained, of preventing pain in severe surgical operations by some thoroughly reliable means? Dr. Wells ascertained, as Sir Humphry Davy had before him, that the inhalation of nitrous oxide renders a person insensible to pain under a slight surgical operation. That was the whole extent of his achievement. How far short it is of the end proposed and actually reached by the Boston gentlemen, would seem to be obvious enough without any danger of mistake. Had the art of producing anæsthesia been left just where Dr. Wells left it when they came upon the scene, nobody can suppose that we should now be performing severe operations without pain. And yet we know even better than he what nitrous oxide can do and what it cannot do in regard to anæsthesia. And now we are asked to award to him the honor of a discovery which required another discovery to make it of any use!

At that same period painless surgical operations were performed under the influence of animal magnetism; and if there is any honor in discovering an anæsthetic of little or no practical use, then surely Dr. Elliotson and Dr. Esdaile are as much entitled to it as Dr. Horace Wells. The gentlemen moving in this matter forget that it makes all the difference in the world whether a great scientific discovery is only conceived and sought for and feebly discerned, or abundantly demonstrated and made available for untold good to coming generations of men.

Some of the more ardent friends of Dr. Wells contend that he discovered the anæsthetic property of sulphuric ether, and thus shut off the claim of Jackson and Morton, founded on the superior powers of that substance. The statement finds but slender support in his own account of the matter. In the pamphlet put out by him in 1847, he says that a "surgical operation" was performed some two or three years before, on a person under the influence of ether. What the operation was, or what was the effect of the ether exactly, we are not told. Indeed, not a single circumstance connected with this transaction is mentioned, beyond the solitary fact that a Dr. Marcey was present. The experiment was far from being satisfactory, for he concluded thenceforth to abandon the use of ether and stick to nitrous oxide.

It seems that Wells was informed by Morton himself respecting the operations at the hospital in Boston; and what does he say in reply? Does he use the opportunity to set forth his own pretensions and insist upon the recognition of his rights, as he most assuredly would if he had done what his friends now claim for him? It is hardly conceivable that any qualm of modesty or delicacy of feeling would have then shut his mouth; and, in fact, on the spur of the moment he acted honestly and naturally. He says to Morton, "If the operation of administering the gas is not attended with too much trouble, and will produce the effect you state, it will undoubtedly be a fortune to you, provided it is rightly managed;" and that is about all he does say.

It is not strange that Hartford people, zealous for the honor and glory of their town, should be disposed to magnify the achievements of their townsman; but when men supposed to be unbiased by any consideration except the love of truth, and accustomed by the nature of their studies to sift and to weigh conflicting evidence, can find in the historical record of the rise, progress, and consummation of the discovery of the means of anæsthesia the slightest support of his claims, then, certainly, we wonder greatly and are perplexed.

JUSTICE.

OBITUARY.

IF we take a retrospective glance at the losses sustained in our profession, here and elsewhere, during the few months just passed, we find the names of several who were but yesterday the representatives of its intelligent, earnest, and hard-working laborers, mingled with those of others whose day of usefulness forms part of the history of a preceding generation. Among the latter we may particularly mention the name of P. C. A. LOUIS, the distinguished French physician and writer, who died in September last, at the advanced age of eighty-five. The Hôpital Charité, Hôtel-Dieu, and Hôpital Pitié were the fields in which his remarkable studies in diagnosis and pathology found fullest scope for their elaboration. It has been said of him that both in his public and private practice his skill in diagnosis was attested so often and so signally by pathological disclosure as to elevate the physician's art into something like the certainty of an exact science. As a writer, he is especially memorable for his re-

searches on Phthisis, on the Yellow Fever at Gibraltar, and on Typhoid Fever, more particularly as regards its differential diagnosis.

FREDERICK C. SKEY, whose death at the age of seventy-two was announced a few weeks since, was an able English surgeon and a popular lecturer. His early professional life was associated with that of the celebrated Abernethy, under whom he was Demonstrator of Anatomy at St. Bartholomew's Hospital. Difficulties which arose in this school upon the death of that surgeon led to the establishment of a formidable organization, embracing the familiar names of Pereira, Hope, R. B. Todd, Marshall Hall, Kiernan, and the subject of our notice, in the successful Aldersgate School of Medicine. Besides occupying other honorable public positions, he was Professor of Human Anatomy and Surgery, and afterwards President of the Royal College of Surgeons; and, in addition to treatises on venereal diseases, stone in the bladder, etc., he published an excellent work on Operative Surgery, which was reprinted in this country.

ALFRED POLAND, Surgeon to Guy's Hospital, also recently died, after a useful and honorable career as a lecturer and practitioner, in which he devoted much attention to ophthalmic surgery, as well as to the general domain of surgical art. He is better known to American readers from the publication of his prize essays on "The Nerves of the Orbit in the Mammalia and in Man," "Injuries and Wounds of the Abdomen," and "Gunshot Wounds and their Treatment;" he was also a contributor to "Guy's Hospital Reports," which he edited, and to Holmes's "System of Surgery."

Our local necrological record interests us even more profoundly. Of the older physicians who have quite recently passed away from their spheres of usefulness we may briefly refer to the names of Drs. Bell, Mason, and Wistar. Dr. JOHN BELL, who died in August, at the age of seventy-six, was a native of Ireland. He was at different periods a lecturer in the Philadelphia Medical Institute and the Medical College of Ohio; and his controversial candidacy for the position of Professor in the University of Pennsylvania, some twenty-five years since, will be remembered by many of the profession. He was a voluminous contributor to various medical journals, as well as the author of a number of works on "Baths and Mineral Waters," "Health and Beauty," "Physical and Moral Management of Infancy," "Regimen and Longevity," etc. He edited the lectures of Stokes on the "Practice of Physic," to which he made numerous and valuable additions; and the conjoint work was, probably on account of the amount of material thus contributed, familiarly known as "Bell and Stokes's Practice." He edited for a number of years, now nearly a third of a century since, the "Bulletin of Medical Science" and the "Eclectic Journal of Medicine," and published in connection with them a variety of excellent works, from the pens of distinguished authors of Great Britain especially.

Drs. JOHN KEMBLE MASON and MIFFLIN WISTAR, the latter the son of the celebrated Professor Caspar Wistar, were valued for their private and social virtues, for which they will be gratefully remembered, rather than for the more public appreciation which follows others in the arena of authorship or the lecture-room.

Dr. AUGUSTIN H. FISH, who died in August, was about forty years of age, a native of Trenton, New Jersey, and studied medicine in the office of Professor George B. Wood. He devoted himself assiduously to the labors of an arduous practice, with a zeal and energy that doubtless told with fatal effect on so slight a physical organization. As a medical practitioner he thoroughly enjoyed the confidence and devotion of his patients, to whom, as to the large circle of his friends, he was endeared by his remarkable integrity, manliness, sterling worth, and high professional morality. When in the vigor of health, he was one of the leading moving spirits of the Philadelphia County Medical Society, and also of the State Medical Society, of which he was for several years the treasurer. Few pass away whose blameless records leave behind so precious memories.

The more recent death of Dr. GEORGE PEPPER has been fully alluded to elsewhere. We may also briefly refer to the loss sustained by the Philadelphia College of Pharmacy in the decease of Professor EDWARD PARRISH, the author of a work on Practical Pharmacy, the popularity of which was attested by the fact that several editions of it were published. The circumstances of his death while acting as a Commissioner to the Indians are generally known. His eminent usefulness as an instructor and his excellent qualities as a man have been the theme of general admiration and appreciation.

BOOKS AND PAMPHLETS RECEIVED.

The Microscope and Microscopical Technology; a Textbook for Physicians and Students. By Dr. Heinrich Frey, Professor of Medicine in Zurich, Switzerland. Translated from the Fourth and Last German Edition, and edited, by George R. Cutter, M.D. 8vo, pp. 658. New York, William Wood & Co., 1872.

The Pathology, Diagnosis, and Treatment of the Diseases of Women, including the Diagnosis of Pregnancy. By Graily Hewitt, M.D. Lond., F.R.C.P., etc. etc. Second American, from the Third London Edition. 8vo, pp. 751. Philadelphia, Lindsay & Blakiston, 1872.

Proceedings of the Pathological Society of Philadelphia. Vol. III. 8vo, pp. 218. Collins, Printer, 1872.

Valedictory Address to the Graduating Class of Jefferson Medical College, at the Forty-seventh Annual Commencement, March 9, 1872. 8vo, pp. 23. Philadelphia, P. Madeira, 1872.

Transactions of the North Carolina State Medical Society for 1872.

GLEANINGS FROM OUR EXCHANGES.

EXCITABILITY OF THE MUSCLES IN CASES OF APPARENT DEATH (M. Rosenthal: *Wiener Med. Presse*, 1872, Nos. 18 and 19; quoted from a review by Bernhardt in the *Central-Blatt für Med. Wiss.*, xxxiii., 1872).—Rosenthal has found that the post-mortem electrical excitability disappears sooner after chronic diseases than after acute maladies, and that this excitability is retained longer in the well-nourished cadaver than in the emaciated. The duration of the excitability varies between one and a half and three hours. Immediately after death no changes in the excitability can be detected, but in the course of one or one and a half hours the direct excitability of the muscles of the face and extremities lessens in the centrifugal direction, while the indirect excitability has already decreased. At this point the temperature in the axilla stood at 35.2° C. Among the facial muscles only the orbicularis palpebrarum and levator alæ nasi et labii superioris reacted under the direct irritation, two hours after death.

By the aid of acupuncture the muscles acted at this trial. The same was true when a galvanic irritation was applied.

Although the muscles of the lower extremities may cease to react, two hours after death, it is possible to produce a powerful reaction in some of the muscles of the

arm, viz., in the abductor pollicis longus and in the extensor carpi ulnaris.

Two and a half hours post mortem, even the orbicularis palpebrarum, the abductor pollicis, and the flexor digitorum respond but tardily to the most powerful excitation, and after three hours even electro-puncture with faradic or very strong constant streams is unable to produce any contraction whatever. The temperature of the rectum at this time was still 32° C., and the joints showed no signs of rigidity.

On amputated limbs Bernhardt found that faradomuscular contractility ceased at the expiration of one and a half to two hours post mortem.

In the case of an hysterical woman who had apparently been dead forty-four hours, and was already prepared for her burial, and in whose case the author diagnosed only apparent death by the presence of excitability in all the muscles, we have an illustration that in cases of suspected "apparent death" our most trustworthy means of diagnosis lies in the condition of the excitability of the nerves and muscles.

Experiments upon animals agree fully with the facts already related in regard to man.

Rabies Canina in Ancient Times (K. F. H. Marx: *Wiener Mediz. Presse*, No. 34, 1872).—In the seventh volume of the Transactions of the Scientific Society of Göttingen, Marx has contributed an exhaustive treatise on "hydrophobia among the ancients," and deduces some practical conclusions for our guidance in modern times. Down to the present time none of the internal remedies have availed in hydrophobia, so that the only anchor of hope is external treatment. For this purpose the best application consists of caustic potash.

Much has been written on the subject of hydrophobia, but most of it is valueless. The author thinks it belongs to the province of psychical medicine. Centuries ago the question was raised, "Does the disease rank as a physical malady or an affection of the mind?" and that remains still the great question.

The chief point to be decided is, whether madness is a *necessary* consequence of the bite of a rabid dog, or only an accident of the morbidly excited imagination and confused reason, induced by the vulgar impression that madness must follow the bite, or by the anxiety of friends and the personal fear of death.

Children attacked by this disease, and unacquainted with the results of the injury, escape spasms and madness.

Furthermore, many adults bitten by a mad dog escape the disease altogether.

The author closes his exhaustive treatise with the following words:

"If we are able, as in olden times, and in the case of children, to instruct or induce men to be perfectly quiet after they are bitten by a rabid dog, not to tremble or be frightened, but to banish anxiety, to control their imagination, and with patience and hope to look forward to recovery, and also to persuade the well to remain with the unfortunate one and not to run away, but to cheer him in the hour of trial, then the means may have been discovered by which the effects of the accident are to be banished and the poison in the wound neutralized."

Dr. G. M. Humphry, of Cambridge, in a clinical lecture published in the *Lancet*, says, "Whether there is much pain or little, whether the patient sleeps or does not sleep, I refrain from giving opium or any other sedative. Pain, even severe and long continued, though hard to bear, does not seem to do the body much harm. I have often been surprised how little wear and damage it does,—not so much, I think, as the sedative which is given for its relief; and the exhaustion of a sleepless, restless night or period is usually followed by sleep, which is more likely to occur naturally at an early period if sedatives have not been used. Under ordinary circumstances, a restless night is less damaging than a night of sleep induced by a sedative. The patient commonly wakes from the latter paler, weaker, lower, more enervated, and less able to bear pain. I have long had this conviction; indeed, throughout life I have acted upon it. It may be regarded as a prejudice; but I think the patients recover better and quicker, and are less liable to pyæmia, erysipelas, and other unfavorable sequelæ of operations when thus treated. These, at any rate, we rarely see in Addenbrooke's Hospital; and our immunity from them is, I think, partly due to the practice of non-interference after operations so generally followed in this hospital. You will understand that I make a distinction between the use of opium as a remedy for disease and as a means of relieving pain after operations. In the former case it is a very valuable medicine under many circumstances,—one of the most valuable we possess. But in the latter case there is no disease; the pain is merely a natural consequence of the physical injury which has been sustained, or of the local changes which are taking place as a consequence of the injury. The condition will generally subside after a short time; and it is much better to allow it to do so, unless there is some special reason for interference."

An Invasion of Wood-Lice (Rudolph Virchow: *Virchow's Archiv*, vol. 54, parts 1, 2, 1871).—Some time ago the medical faculty of Berlin received from the curate in Parstein, Prussia, a large number of small insects, with a request for an explanation of their nature. The curate stated, in an accompanying letter, that during repairs to an old hotel near the house of one of his parishioners, the home of the latter had been invaded by myriads of insects of an unknown nature.

They had filled every crevice and covered all the clothing and persons of the inmates of the house of the afflicted man, and had defied all attempts to extirpate them.

They had so annoyed the owner of the invaded house that his health had materially failed.

Dr. Gerstäcker, to whom Virchow had submitted the specimens, pronounced them to be small orthoptera, of the family of wood-lice known as psocina, and were indeed the Clothilla inquilina of Heyden. Gerstäcker further remarked that such an invasion of the dwellings of man by these insects had never been reported, and that they were closely allied to the well-known book- or paper-louse, the Troctes pulsatorius, L. (Gerstäcker und Carus, Zoologie, ii. S. 58).

The event reminds us strongly of the invasions of Leptus autumnalis, many of which are on record.

From the information contained in the letter which accompanied the insects, it was impossible to make out the nature of the bodily annoyance experienced by the unfortunate and tormented housekeeper: nevertheless, the case is worthy the attention of physicians.

Cold Affusion.—The first meeting of the Clinical Society of London (Oct. 11) was signalized by an exceedingly important discussion on the treatment of high temperature by cold affusion. Dr. Southey read an account of a case where a patient, the subject of rheumatism, became delirious with a moderately high temperature. Cold water was used, and the temperature reduced, whereupon the delirium abated and the patient got quiet sleep; but the temperature went up again, and the delirium returned. Again it was reduced with favorable results; but, though this was repeated frequently, the patient ultimately died quite worn out. In a case of Dr. Greenhow's, a somewhat similar history was recorded. In this, too, a fatal course was the result. The question accordingly arises, In what cases should

cold be used to reduce temperature? Dr. Wilson Fox, whose experience is great, distinctly lays down the rule that the cold-water bath should only be used when the bodily heat rises to a great height and itself threatens a fatal termination. This temperature he put at 106.5° or even 107° Fahr. The President, Sir W. Gull, mentioned a case in which the temperature was 107.5°, and in which two immersions cured the disease. In Dr. Southey's case there were bronchial complications, and there was an uneasy feeling that they were due to the cold. Dr. W. Fox, however, said that such complications happened quite as readily with high temperatures where no cold was used as with cold baths. There was an idea expressed that very large doses of quinine might be found to act as a substitute for cold water in reducing bodily heat.

THE HOT-SAND BATH.—A correspondent of the *Medical Times and Gazette* says, "Fresh from the enjoyment of a delicious therapeutical novelty, and being, as I believe, the *corpus vile* on whom the first experiment has been made in London, I beg to call the attention of my professional brethren to the hot-sand bath which has been established by Dr. Conradi at 22, Aberdeen-place, Maida-hill.

"The patient is introduced into a warm, comfortable room, in which is a bath, fenced round with curtains, filled with sand heated to about 100° to 120°. In this a longitudinal groove (I will not say grave) is scooped to receive the patient, who is wrapped in a sheet, and so protected from contact with the sand. There is a comfortable pillow for the head.

"Then the bath operator gradually covers up feet, legs, arms, and trunk with the warm sand. A bucket of hotter and one of cooler sand are at hand, so that the temperature can be adjusted with the greatest nicety. The feeling of warmth is very agreeable, and the weight of the sand is just enough to cause a pleasant sense of compression and support. After an hour's delightful repose, the patient rises, is refreshed by a sluicing with hot water, and goes away refreshed.

"The effect is very different from that of hot water, and still more from that of hot air or steam. There was absolutely no commotion of the heart, nor any of the grilling effect on the windpipe which I have experienced in Turkish baths. Altogether, it seems a good thing when we want to produce measured perspiration and relieve congestion of the internal organs."

ETHER VERSUS CHLOROFORM.—We find the following in the *Clinic* (Chicago) of November 2, quoted from the *British Medical Journal* of October 12: "If the force of statistics be of any value, ether, beyond question, is the agent which presents the most powerful claims and must obtain our confidence as the safest anæsthetic. The reports at the Medical Society of Virginia during this session are conclusive: by combining American and British statistics, the result is found to be as follows:

Agent employed.	Deaths.	Inhalations.
Ether	4 to	92,815, or 1 in 23,204
Chloroform	53 to	152,260, or 1 in 2,873
Mixture of Chloroform and Ether	2 to	11,176, or 1 in 5,588
Bichloride of Methylene	2 to	10,000, or 1 in 5,000

"It is thus proved statistically that chloroform is eight times as dangerous as ether, twice as dangerous as a mixture of chloroform and ether, and, as far as experience goes, it is more dangerous than bichloride of methylene; in fact, chloroform is the most dangerous of all the anæsthetic agents in use. If statistics are of any value, these should be startling and impressive ones. The report of the London Chloroform Committee states the result of careful investigation, that 'ether is less dangerous than chloroform;' and that 'with every care and the most exact dilution of the chloroform vapor, the state of insensibility may pass in a few moments into one of imminent death;' and the latest surgical work from America advocates ether as the most suitable anæsthetic."

REMOVAL OF A STONE FROM THE KIDNEY—DEATH.—Dr. Dawson presented to the Academy of Medicine in Chicago, October 26, a phosphatic renal calculus seven-eighths of an inch in length, half an inch in breadth, and weighing 20¾ grains, removed by him from the left kidney of a woman fifty years of age. An abscess had formed, and was three times exhausted of pus by the aspirator, within the five days preceding the operation. This was done under chloroform, an incision being made along the edge of the erector spinæ muscle, from the eleventh rib to the crest of the ilium, and a dissection made to the depth of 2¾ inches, when the cavity of a sac, composed of the degenerated kidney substance, was entered. After the extraction of the stone, a drainage-tube was inserted, and the wound closed.

For four days the patient did well; pyæmia then set in, and death ensued in less than twenty-four hours.

RUPTURE OF THE UTERUS; SUCCESSFUL GASTROTOMY.—In the *Medical Times and Gazette* of September 21 a case is quoted from the *Bulletin de Thérapeutique* in which, December 18, 1871, four days after rupture of the uterus with escape of the fœtus and annexes into the abdominal cavity, gastrotomy was performed by Dr. Fourrier, of Compiègne. "The left iliac fossa was found to be lined with a blackish membrane in shreds, which was afterwards determined to be the peritoneum in a state of gangrene." No hemorrhage ensued; the case went on well, with some fluctuations, for about four weeks, when enteritis, and what was at first feared to be purulent infection, set in. Quinine was given in large doses with good effect. By February 19, 1872, the patient was considered quite well, and in May the menses reappeared.

The woman was seven or eight months gone in her pregnancy when the rupture occurred.

A WRITER in the *Australian Medical Gazette* advocates the inhalation of chloroform by pouring about thirty drops of the article on a handkerchief, breathing it in for a few seconds gently, and then as forcibly as possible.

He thinks this method perfectly safe,—which remains to be proved, as he adduces only four cases, though he claims to have had others in which it had been used by him. [It seems to us much like Simpson's plan of pouring the chloroform, drop by drop, on a single layer of thin stuff placed over the mouth; and a friend assures us that he has seen death occur when this was used.—ED. P. M. T.]

MISCELLANY.

A CORRESPONDENT sends us the following:

"'NOSE MACHINE.—This is a contrivance which, applied to the nose for an hour daily, so directs the soft cartilage of which the member consists, that an ill-formed nose is quickly shaped to perfection. Any one can use them, and without pain. Price 10s 6d, sent carriage free.—ALEX. ROSS, 248 High Holborn, London. Pamphlet sent for two stamps.'

"The above advertisement appears in the London *Spectator* of a recent date. We hasten to give it circulation. We know of people whose noses have been to

them sources of life-long torment,—noses retroussé to such a degree that to follow them, as the wayside proverb directs, were spiritually wise; pug-noses deftly buttoned into a breadth of face,—noses of innominable form, flabby, and elusive of the handkerchief; Thackerayan noses, more amazing for what they lack than for what they have,—making the profile like that of the faces we used to bite out of gingerbread when we were boys; and, lastly, the noble Eastern nose, a tower of sadness to him whom, having wandered from his fathers' ways, the signs of race discomfort. Good news to one and all, or to such, at least, as begin early to train their noses in the way they should go, and whose cartilages are of a submissive gelatine. For the first time we are led to reflect as to how much of nose-character is bone, and how much is jelly (fair subject for a prize essay); for, as all great generals have had great noses, there may be, too, a nose in its intimate essence professorial, which, obtainable by aid of art, may bring a man to this crown of medical glory ere yet his beard be gray.

"Also, in the *Guardian*, a well-known high-church paper, we find a gentleman who advertises for second-hand sets of artificial teeth. What does he do with them?"

Suicides in France in 1870 (*Medical Times and Gazette*, August 31, 1872).—The French *Journal Officiel* has recently published the "Report of the Administration of Criminal Justice in France for the Year 1870." The following are the passages that relate to suicides:

"During 1870 there have been brought under the notice of the Administration 4157 completed suicides; 3371 (81 per cent.) occurring in men, and 786 (19 per cent.) in women. The ages of 10 individuals are unknown; 18 were less than 16 years old; 130 between 16 and 20; 1067 between 21 and 40; 1669 between 40 and 60; and 1243 were 60 and upwards. As to their civil status, 1447 were unmarried; 1380 married, with children; 599 married, without children; 464 widowed with, and 199 widowed without, children. There were 2630 inhabitants of rural districts, to 1461 inhabitants of towns, the domicile of 66 being unknown. With respect to their occupations, 1848 belonged to agricultural, 933 to the various forms of industry, 119 were merchants or shopkeepers, 716 were of the liberal professions, 116 were servants, and 395 without avowed occupations. Of the 4157 suicides, 1384 took place during spring, 1129 in summer, 668 in autumn, and 976 in winter. As in former years, hanging and drowning have been the most frequent means of death resorted to. The presumed motives were misery and reverses in fortune in 383, family discords in 512, love, jealousy, debauchery or other misconduct in 701, various forms of suffering in 930 (these being physical in 515), and cerebral disease in 1377. In 22 instances suicide was committed by the authors of capital crimes, and in 232 the probable motive could not be assigned."

It is not yet many years since (1838) it was said that arsenic was a normal constituent of the human body, existing especially in the bones. This was as far as possible disproved by Flandin. Doubtless the arsenic, if any existed, was in the reagents employed by Orfila, who made the so-called discovery. Even now it is by no means certain whether arsenic does not exist naturally in many soils. Dr. Taylor says he has extracted an unmistakable quantity of arsenic from earth taken from churchyards in the North of England. Such statements necessitate the utmost care in removing bodies from the ground and in putting up the parts intended for analysis. An interesting case is narrated of a gentleman who, after removing a stomach for analysis, being called away in haste, wrapped it in a piece of wall-paper, the clean side next the organ. On analysis, both morphia and arsenic were found in the stomach, the origin of the last not being apparent until the paper was more carefully examined, when it was discovered to be colored with arsenic. The history of the case contradicted the use of arsenic in it: had it not, a false charge of arsenical poisoning might have been brought.

Superstition.—The Paris correspondent of a daily paper says,—

"Another swindling operation is also to be put down by the police,—to wit, the sale of magic plants by the herbalists. It will be scarcely credited that in Paris, in the nineteenth century, there is an immense consumption made of these sorts of herbs, of which very small portions are sold at fabulous prices. Thus, a piece of mandrake, gathered when the moon is full, costs at least fifty francs. A single leaf of azedarach, upon which, on the last Saturday of the month, has been pronounced the grand cabalistic formula of King Solomon, finds easily a purchaser at one hundred francs; while a bundle of moss which a centenarian has stewed up in a saucepan with two frogs and the skull of a man who has committed suicide, is looked upon as a bargain at two hundred. It is almost superfluous to add that moss, mandrake, and azedarach are nothing but common weeds, bought for a few centimes in the morning at the herb-market of the Rue de la Poterie, and raised by credulity and ignorance to the dignity of magic plants."

Importance of Clean Bottles.—A case of poisoning is reported in the *British Medical Journal*, under the following circumstances: A child, two weeks old, was ordered dill-water, which was procured in a bottle previously containing a preparation of opium and bearing a label to that effect. The bottle was empty, what liquid there had been in it having dried up, leaving a deposit on the sides and bottom. The dill-water dissolved the residue, and, upon analysis, was found to contain morphia and meconic acid. A teaspoonful was given to the infant, who immediately thereafter fell asleep. His breathing changed within an hour, followed by convulsions and narcotism. He died the following day.

Pharmacy at Sea.—The *Chemist and Druggist* contains a story of a sea-captain to whom a sailor applied

for relief for "something on his stomach." The captain consulted his book of directions, and prescribed "No. 15." Unfortunately, however, there had been a run on No. 15, and the bottle was empty. But the skipper, remembering old games of cribbage, made up a dose by combining No. 8 and No. 7, saying "8 and 7 make 15;" and the sailor, to whom the calculation seemed quite natural, took the mixture with startling effect.

Too Much Medicine.—The New Bedford (Mass.) *Mercury* says the medicine-chest of one of the abandoned Arctic whalers was broken open by some of the natives, who, thinking they had found a prize, proceeded to swallow the contents of all the bottles. The survivors described the result as startling; for the doses were too large for the constitution of even an Esquimaux. Several of the partakers died, and others wanted to, but couldn't.

The Obstetrical Society of London has appointed a committee to form a collection of pelves, illustrative of various points in connection with obstetrics. The Hon. Secretaries to the Pelvis Committee state that they will be willing, if desired, to make arrangements as to expense of carriage, casts, models, drawings, photographs, etc., with any society or gentleman in this country who may wish to contribute specimens. Their address is at the Society's Library, 29 Regent Street, W.

The *Leavenworth Medical Herald* of October 1 says, "We have before us a curiosity in the shape of a medical work, published in 1759, consisting of a 'Collection of the Yearly Bills of Mortality in London, from 1657 to 1758, inclusive.' From among the causes of death we select the following: Headmouldshot, Horseshoehead, Twisting of the Guts, Rising of the Lights, Stoppage in the Stomach, Livergrown, Strongullion."

A return completed for the year 1870 shows no less than 330 coroners in England and Wales,—233 for districts in counties, and 97 for boroughs. The great majority of them are elected by the freeholders or town councils; but in some cases by charter or prescription the appointment is made by the lord of the manor. It would be interesting to have officially the relative number of medical and legal coroners.

The returns of the mortality for 1870, just published, show that during that year the deaths of 18 males and 63 females whose ages were stated to be upwards of 100 years were registered,—in all 81 persons, against 63 and 79 respectively in 1869. The highest ages said to have been attained in 1870 were—108 by a male who died at Stone, in Staffordshire, and 107 by a female who died at Huddersfield.

Bravery of a Medical Officer.—In General Orders No. 99, from the Headquarters of the U. S. Army at Washington, reporting an engagement with hostile Indians on the 29th of September last, by an expedition under command of Colonel R. S. McKenzie, of the 4th Cavalry, "Acting Assistant-Surgeon Rufus Choate is commended for his care of the wounded under fire."

M. Legrande du Saulle, physician at the Bicêtre and the Depôt of the Prefecture of Paris, says the number of lunatics brought to the Depôt in the summer of 1871 was much below the average. A writer in the *Gazette Médicale* explains this by saying that during the Commune people could hardly diagnosticate a lunatic from a "Red;" and after the collapse of the revolution the Chassepot proved a most effective, though a deplorable, remedy.

A Serious Joke.—A typographical error makes a contemporary credit Dr. G. M. Beard, of New York, with the writing of a pamphlet on the "*Comic* Law of Intemperance."

Mr. Arthur E. Durham will succeed the late Mr. Poland as Surgeon to Guy's Hospital.

Mortality of Philadelphia.—The interments reported at the Health Office for the week ending Nov. 23, 1872, were 244; 146 adults, and 98 minors. 15 were of bodies brought from the country; making the mortality of the city 229. Among the causes of death were:

Consumption of the Lungs	34
Other Diseases of the Respiratory Organs	31
Diseases of the Circulatory Apparatus	11
Diseases of the Brain and Nervous System	40
Diseases of the Digestive Apparatus	20
Zymotic Diseases (1 from Smallpox)	14
Typhoid Fever	5
Casualties	5
Intemperance	2
Murder	1
Suicide	1
Debility (including "Inanition" and "Marasmus")	18
Still-born	24
Old Age	10

(The interments reported for the week ending Nov. 25, 1871, were 394.)

The meteorological record kept at the Pennsylvania Hospital was as follows:

	Thermometer. Max.	Min.	Barometer. (2 P.M.)
Nov. 17	37.0°	25.0°	30.63 in.
" 18	44.0	32.0	30.38 in.
" 19	41.0	30.5	30.21 in.
" 20	41.0	30.0	30.14 in.
" 21	27.0	24.5	30.42 in.
" 22	36.0	32.0	30.08 in. (Rain.)
" 23	43.0	34.0	30.33 in.

OFFICIAL LIST

OF CHANGES OF STATIONS AND DUTIES OF OFFICERS OF THE MEDICAL DEPARTMENT U. S. ARMY, FROM NOVEMBER 12, 1872, TO NOVEMBER 18, 1872, INCLUSIVE.

McKee, J. C., Surgeon.—Granted leave of absence for fifteen days. S. O. 220, Department of the East, November 13, 1872.

Forwood, W. H., Assistant-Surgeon.—Assigned to duty as Post Surgeon at Fort Richardson, Texas. S. O. 200, Department of Texas, November 7, 1872.

SATURDAY, DECEMBER 7, 1872.

ORIGINAL LECTURES.

CLINICAL LECTURES ON PROLAPSE OF THE WOMB.

BY WILLIAM GOODELL, M.D.,

Physician-in-Charge of the Preston Retreat; Clinical Lecturer on the Diseases of Women and Children in the University of Pennsylvania.

(Continued from page 131.)

UP to this point we have learned that the cervix uteri, the inverted vagina, a pouch of the bladder, a rectocele, and the two peritoneal folds combine to make up this large hernial mass. This much is evident; but what is it? It is clearly not the vaginal cervix unduly elongated, because it, and only it, would compose the tumor. Can it be an inversion of the womb, or a simple descent of the womb? Or are we dealing with a hypertrophic elongation of the supra-vaginal cervix? These are questions, gentlemen, which the uterine sound will readily answer. For a distance of three and a half inches it meets with no obstruction, but now there is a hitch to its further progress. It has not, however, reached the fundus, but the bend of a retroflexion: this I know from my past experience in gauging these tumors. By a little coaxing, and by raising the handle of the sound, the tip slips onward an inch and a half more before it fairly impinges upon the fundus. Five inches, therefore, is the length of the uterine cavity, as measured from the apparent apex, or false os, of the cervix to the fundus. But if to this the everted portion of the cervix be added,—as it should be, by restoring the os externum to its proper position,—then the uterine cavity will, in reality, measure about six inches. The case, then, is not one of inverted uterus, else there would not be a uterine cavity. Neither is it one of simple descent, because the sound has proved not only a condition of preternatural elongation, but the fact that the fundus is high up in the pelvis. This completes our diagnosis; for, by exclusion as well as by direct evidence, it is as clear as noon that we have before us a case of so-called "*prolapse of the womb from hypertrophic elongation of the supra-vaginal portion of the cervix.*"

Every departure from health, every manifestation of disease, is the product of a train of influences which it is the business of science to track out. Let us try to unfold their significance in this case, beset though it is with so many difficulties that I have postponed its discussion to this the last week of the spring course, in order that all of you might be sufficiently advanced to catch the drift of argument. Four theories have been advanced,—and I now bespeak your earnest attention,—four interpretations of the phenomena, which at first blush seem hopelessly irreconcilable, and which yet have much in common. These theories are as follows:

(*a.*) That the primary affection is a downward growth, a true hypertrophic elongation, of the supra-vaginal portion of the cervix; and that the prolapse of the vagina and bladder is secondary, being the necessary result of the former. (*b.*) That there are no changes of structure in the cervix, other than the strictly mechanical one of elongation, which is a secondary accident, consequent upon the traction exerted by a primary prolapse of the vagina and bladder. (*c.*) Martin's (*Boston Gynæcological Journal*, 1871, pp. 230, 307),—that the circular hypertrophy of the vaginal portion of the cervix, of which the eversion of the os is the result, is a disease *sui generis;* and that it constitutes the weight which lengthens out the supra-vaginal cervix. (*d.*) Isaac E. Taylor's (*Bellevue and Charity Hospital Reports*, 1869),—that, contrary to the commonly accepted belief, the glandular portion of the cervix during gestation is not effaced, but hypertrophied, and that even after labor it still exists; for it has undergone nothing more than a momentary expansion of its canal for the passage of the fœtus; that consequently, if the natural process of involution does not take place, the gravity of this hypertrophied cervix will aid and sustain the elongation of the non-glandular part of the supra-vaginal cervix, viz., the isthmus, which is thick, soft, and ductile in the non-involuted womb.

Now, to my thinking, each one of these theories contains germs of truth, but no single one is of itself adequate to explain all the phenomena. For instance, granting that the disease is a true hypertrophic elongation; then, according as the suspensory ligaments of the womb are more or less yielding than its vesical and vaginal abutments, one of two things ought to happen: either the cervix must grow downward, carrying along with it the bladder and vagina, or else the cervix must grow upward, lifting the body of the womb higher and higher in the cavity of the abdomen. But the upward form of displacement never happens, to my knowledge, in this affection, although it is common enough whenever a fibroid in the lower segment of the womb begets a true hypertrophy of the cervix. Again, in this affection the upper portion of the cervix is cylindrical and of uniform size, but attenuated, as if wire-drawn, rather than hypertrophied. By firmly compressing the base of the tumor, I can feel and trace high up a firm cord-like body not thicker than my little finger. That such a shape cannot be attributed to growth alone, witness the bulbous and nodulated form of the vaginal cervix in cases of chronic cervical metritis. But growth combined with traction will produce this cord-like and symmetrical form. In Oriental countries, for example, where fancy prices are paid for jasmine pipe-stems eight and ten feet in length, the wood is made straight and of uniform size throughout by reeving a pulley and fastening one end of the cord to a growing shoot, and the other to a weight. Further, counter to the theory of growth alone is the telling fact that after a few days of rest in bed the uterine cavity will be found very much shortened. True hypertrophy implies a change of structure in-

capable of speedy resolution; even with the actual and potential cauteries it takes months to melt down a cervix enlarged by metritis. Hence this quick reduction in length is a behavior impossible in hypertrophic elongation. Once more, the so-called supra-vaginal portion in this patient is dense and hard, whilst the infra-vaginal portion is soft and spongy, as if its substance had been absorbed. The former is stem-like, the latter clubbed. There are extremely few cases—according to Huguier and Savage there are none—in which the two kinds of hypertrophic elongation coexist in the same cervix. The elongation is in fact limited either to the supra- or to the infra-vaginal portion; very rarely indeed does it affect both portions of the same cervix. Such an exclusiveness does not comport with the theory of hypertrophy; for how thereby explain this lack of concord in the behavior of two portions of one continuous structure? Is it reasonable to suppose that a merely superficial muscular collar, such as the vaginal attachment, can act like a conjurer's ring, and, by a sort of magic, inhibit deeply-seated tissue-changes on one side of it from passing through to the other? Rather than be embarrassed by this difficulty, I much prefer to apply the aphorism of the schoolmen,—*quod non habet, dare non potest*, a cause cannot communicate what it does not itself possess,—and consequently that the elongation, if supra-vaginal, is not communicable because it is not essentially hypertrophic. I say *essentially*, because I am willing to concede some degree of growth, not primary but secondary, caused by the irritation of another factor,—traction,—and by the stasis in the circulation induced by it.

If these arguments are sound, we must reject this theory. Nor should that of Martin's, if taken by itself, fare any better; for, if the weight caused by a circular hypertrophy of the vaginal portion can lengthen out the supra-vaginal portion, why cannot the same effect be produced by the far heavier weight of a cervix elongated in its infra-vaginal portion, of a cervix greatly hypertrophied eccentrically by chronic metritis, or of a large polypus or cancer of the cervix? Dr. Isaac E. Taylor—to whom the profession is greatly indebted for first showing that the cervix uteri is not effaced either by gestation or by parturition—has advanced an ingenious theory, which hinges upon this stability of the cervix, and has the great merit of consistency. His testimony regarding the autopsic lesions of this disease shows conclusively, if I understand him correctly, that the elongation does not affect the glandular portion of the cervix, but that portion of the womb just above the os internum, at the junction of the body with the neck. In other words, it is the supra-glandular portion of the cervix—the isthmus—which is drawn out from the corpus, and that at the expense of its thickness. Other observers have demonstrated that the glandular portion is hypertrophied circularly, not longitudinally; and this statement is further confirmed by the two important facts: first, that the internal os, so far from being separated more widely from the external os, is, by eversion of the cervical canal, often brought nearer to it; and, secondly, that the vesico-uterine peritoneal fold, instead of receding from the end of the tumor, approaches it so closely as to run some risk in the operation for its amputation. Granting, then, these premises, I think we are logically forced to admit, in the non-involuted uterus, not only the ductility of its isthmus and corpus, but also the gravity of its hypertrophied cervix. I shall, therefore, invite you to accept Dr. Taylor's theory; not, however, as one covering the whole causation of this affection, but as one throwing additional light upon it.

Of the four theories presented to you, let us now provisionally adopt the second one,—that of primary prolapse of the vagina and bladder,—in order to see how far it meets the phenomena. I speak and shall speak of the conjoint prolapse of the vagina and bladder, because from the fusion of the anterior wall of the vagina to the base of the bladder, a prolapse of the one must be accompanied by that of the other; and, therefore, in the study of the mechanism of elongation, it is immaterial to us which of these organs is the first to prolapse. Should, then, the vagina and bladder prolapse, they plainly must conspire either to drag down the womb as a whole, constituting a simple prolapse, or descent, of the womb; or else, in case the uterine ligaments resist this traction, to pull upon and stretch out the isthmus and lower portion of the corpus—viz., that portion of the womb lying between the vesico-vaginal attachment below, and the uterine ligaments—or, perhaps, pelvic adhesions—above.

Now, in fact, this very thing happens in this affection. The elongation is limited to that portion of the cervix and corpus just above the os internum, which would be dragged upon; and does not extend to the glandular portion, which would not be dragged upon, and which, therefore, could not increase in length, save only by growth. That the healthy womb is a somewhat ductile body, capable of extension without growth or change of structure, is proved by its behavior under steady traction. Thus, when adherent to the wall of a growing ovarian cyst, it has been found stretched out to a length of six or more inches. I have seen the same thing happen to a womb firmly bound to the cyst of a ventral fœtation; and this is a happier illustration, because the womb is always so jealous of an extra-uterine pregnancy as to form a decidual membrane, and to present such characteristics of post-partum sub-involution as congestion, softening, and ductility. In these cases the elongation is analogous to that predicated of a prolapse of the vagina and bladder, but in an opposite direction,—from below upwards,—the static, or resistant, force being now in the vesico-vaginal attachments; the dynamic, or active, force in the adhesions to a growing cyst.

Thus far this theory of traction has analogy and the autopsic lesions on its side. It also has the further merit of explaining how a few days' rest will bring about so marked a diminution in the length of the womb. Thus, the recumbent posture removes the weight of the prolapsed organs, and the womb shrinks up like an over-stretched

rubber band. It may, however, be reasonably objected, that since neither the weight of a very large polypus growing from the cervix, nor that of a vaginal cervix hypertrophied circularly or longitudinally, does materially lengthen out the supra-glandular cervix, it does not seem plausible that the lesser weight of the prolapsed vagina and bladder should effect that which greater weights fail to do. This objection can be met by assuming that, either through chronic congestion or through arrest of post-partum involution, the womb is thick, soft, and ductile,—conditions which of themselves would tend to make the gravity of the cervix act upon the plasticity of its intermediate portion. For instance, —to borrow a homely illustration from our candy-pulling days,—if a rope of molasses candy is held out at arm's length, the weight of its free extremity will draw out and thin out that portion just below the grasp of the hand. To sum up, then: the predisposition to this disease depends upon a tendency to cystocele or vaginocele; the receptivity, upon the coexistence of sub-involution or of its analogues.

(To be continued.)

ORIGINAL COMMUNICATIONS.

ON THE EFFECTS OF THE BROMIDES IN EPILEPSY, WITH SPECIAL REFERENCE TO THE BROMIDE OF POTASSIUM.

BY M. GONZALES ECHEVERRIA, M.D.,

Resident Physician to the New York City Asylum for the Insane, Ward's Island, N.Y; Consulting Physician to the New York Hospital for Epileptics and Paralytics, etc. etc.

(Continued from page 136.)

I WILL now compare the value of the bromide of potassium in the treatment of epilepsy with that of its following kindred salts: bromide of sodium, of calcium, of lithium, of ammonium, and of cadmium.

I have tried the bromide of sodium in 128 epileptics; 36 had never before used bromide of potassium, and the remaining 92 had been previously under it. Of the first, 22 were males, and 14 females. The respective ages of these patients were: in the first category, 2 children, 13 adolescents, 7 adults, total 22 males; 3 children, 6 adolescents, 5 adults, total 14 females. In the second category: 8 children, 29 adolescents, 18 adults, total 55 males; 6 children, 22 adolescents, 9 adults, total 37 females.

The bromide of potassium was stopped for one week with the epileptics who were using it, with relief to their fits, which previously had occurred from one to eleven times a week. A solution of bromide of sodium was at first employed in every case, beginning with twenty grains three times a day, and gradually carrying every single dose up to thirty, forty, and sixty grains. The physiological effects of such large doses were identical with those of the bromide of potassium. The eruption of the skin occurred in 82 cases, and 64 became very much troubled with obstinate constipation, gastralgia, and loss of appetite, accompanied with headache. The fits diminished in 14 of the 36 first cases, and in 35 of the 92 second they became better controlled when the bromide of sodium was combined with conium or ergotine. I should, however, state that the maniacal excitement of the epileptic insane remained scarcely influenced by the bromide of sodium, and that several of those epileptics who were previously taking bromide of potassium demanded to return to their old mixture. Their attendants also noticed the retrograde change in their mental condition. A series of observations renewed at different intervals, and throughout periods extending from four to eight weeks, led me to conclude that the bromide of sodium cannot supersede the bromide of potassium. In regard to the innocuity claimed for the bromide of sodium, and which rests a great deal on pure speculation, I may state that throughout my long experience with the bromide of potassium I have never met with any fatal result from its long continuance in the manner here described, and I have used it, within the last twelve years, in cases of epilepsy and epileptiform diseases certainly amounting to more than six hundred, as evinced by the hospital records.

I have administered bromide of calcium to thirty-two adults and four children, epileptic, in doses of from twenty to forty grains, three times a day. The experiment in some of the cases extended to three or four months; and I may add that all but six of the patients, two males and four females, had never tried the bromide of potassium. I cannot say that any positive relief was observed in the severity or frequency of the attacks, whether the salt was given alone or with conium. In eight epileptics, three males and five females, the stomach could not bear the salt in twenty-grain doses repeated thrice a day, dyspeptic symptoms supervening with painful constipation, which forced the salt to be abandoned. Nor have we obtained among the numerous cases of alcoholic mania received at this asylum the hypnotic effects claimed on behalf of the bromide of calcium, which has been administered unsuccessfully, under the circumstances, in thirty-grain doses renewed every hour until one drachm and a half was reached.

The bromide of lithium has proved more active in its hypnotic properties than the bromide of calcium or of sodium. I have prescribed it to twenty-two epileptics never before submitted to the bromide of potassium, and for a length of time varying from six weeks to three months. In two cases, both females, the fits diminished in frequency and severity; the patients were then placed under the bromide of potassium; they went for two months without one fit; they then returned to the bromide of lithium, when they had three fits during the same length of time. They have been now ten months under the bromide of potassium, and one of them has had only one fit. The other patients, eight males and twelve females, have been benefited in a decided manner by the bromide of potassium. In five cases where the bromide of potassium failed to arrest the fits and maniacal excite-

ment, the bromide of lithium—forty grains within three hours—did not act more effectively. Then again, twenty grains of bromide of lithium taken three times a day, by two adolescent female epileptics, superinduced great congestion of the kidneys, a condition, indeed, verging on nephritis.

I cannot say that I have noticed any positive uniform results of the bromide of ammonium in epilepsy, although Brown-Séquard holds that the combination of the bromide of potassium and the bromide of ammonium increases their good effects in this disorder. The latter exerts a special action on the larynx and pharynx, lessening their reflex sensibility, and producing, after at first stimulating the nervous system and cardiac activity, cerebral congestion and stupidity in less doses than any of the bromides hitherto considered. The unbroken current of evidence furnished by experiments I have repeated in hospitals and on private patients leads me to the conclusion that there are no real adjuvant effects derived from the association of the bromide of potassium with the bromide of ammonium; that in epilepsy the same benefit is derived from the use of the bromide of potassium alone; and that I do not recall to mind one single instance where the bromide of ammonium, in doses of from ten to thirty grains three times a day, continued for as long a time as fourteen months in different cases, has arrested the fits, although it diminished them in a few instances at the commencement of the treatment. Let me again state that conium and ergotine were, under the circumstances, also administered with the bromide of ammonium. Nor have I remarked, as advanced by Brown-Séquard, that the two salts under consideration, combined in large doses, would not produce bromism, while a smaller dosê of either alone would produce it,—a fact which has been contradicted by our experience at the Hospital for Epileptics and at this asylum. I may further assert that the addition of the bromide of ammonium to the anti-epileptic mixture has very often superinduced dyspeptic trouble, with strong objection on the part of the patients to persevere with it.

I have administered the bromide of cadmium to three inveterate epileptics,—one male and two females. The bromide of potassium had been employed in their cases with very unsatisfactory results. They had attacks almost daily, attended in the male with mania, lasting from two to three hours. One of the females had also *petit mal*. I began with half a grain of bromide of cadmium in half an ounce of orange-flower water three times a day. The effects were not so perceptible with the man as with the women, who experienced a feeling of sickness at the stomach, purging, and marked diminution of the pulse, falling respectively down from 86 to 72 and from 90 to 74. They also complained, upon taking the third dose in the evening, of a very strange feeling in the head, sickness with burning at the stomach, great looseness of the bowels, and thirst, and one of them had a severe fit, after which she remained more disturbed than usual, and vomited. Both women were so much upset by the bromide of cadmium that they refused to take it any longer. Both were adolescents.

One grain of the salt, prescribed as above, determined the most prompt and pronounced effects in the man, while he was in a state of epileptic insanity. In less than ten minutes he was covered with a clammy perspiration, and seized with nausea and vomiting, until he fell into a semi-comatose condition, with pupils enlarged, very feeble pulse at 46, slow action of the heart, involuntary passage of urine, and such general prostration and copious purging that stimulants had to be administered to him and warm applications constantly kept to the skin. He recovered from this condition in about two hours, still raving, very thirsty and depressed, and had two successive fits in the night, followed by great excitement. This man was an adult: the violent vomiting with purging and extreme depression observed in his case, as well as the results exhibited by the two women, discouraged me from persisting in further experiments with the bromide of cadmium, which, as already shown by Belgrave, is a powerful emetic, capable of operating on the nervous system only in an indirect manner.

Turning now to the bromide of potassium, I may assert that, by itself, it has not in epilepsy the beneficial effects which it acquires when combined with conium and ergotine, to suspend reflex excitability of the spinal cord, which is one of the most important elements in the production of convulsions. It is also necessary to remark that ordinarily the hypnotic properties of the bromide of potassium are powerless to subdue mental excitement in epilepsy or insanity, unless we administer the salt associated with some other narcotic,—a fact of great practical value, but hitherto unnoticed by authors. In epileptic insanity, in mania, in delirium tremens, large doses of bromide of potassium, given alone, generally fail to put the patient to sleep; if any drowsiness be superinduced, it does not last long, and on the patient coming out of it, the maniacal excitement, whether epileptic, alcoholic, or of any other nature, recurs with its former intensity. Let, however, conium, cannabis indica, hyoscyamus, or, better yet, ergot of rye, be added to even moderate doses of the bromide, and the result will be a prolonged and refreshing sleep, followed by quietness. A combination of chloral and bromide of potassium in equal parts, from fifteen to twenty grains of each, is also most useful to produce sleep when either of them alone fails as an hypnotic. Experience, therefore, bears me out in stating that, ordinarily, in insanity large doses of bromide of potassium are ineffectual to induce sleep or to arrest great mental excitement, unless associated with some narcotic. My results with opium in epilepsy have been of an unfavorable character. I have found that opium has only tended to increase the violence and severity of the attacks, and has proved powerless against the maniacal excitement attending the fits. Morphia may, with great precaution, be employed as a cerebral tonic to induce quietude and sleep, after a series of fits, when epileptics remain devoid of all energy and very low, but even then it is a dangerous medicine and very uncertain in its results. I have successfully employed morphia and bromide of potassium associated, or alternating with each other, in melan-

cholia, as suggested by Belgrave, and I have further noticed the corrective influence of the bromide of potassium over opium, pointed out by Professor Da Costa of Philadelphia; but, I repeat, my experience with opium, alone or with the bromide, in cases of epilepsy, has been unsatisfactory.

I have long ago shown at my clinics that, unless administered along with large doses of ergot of rye and conium, the bromide of potassium has very little or no influence on the *petit mal* or epileptic vertigo,—a fact which has been more recently corroborated by Voisin, but simply in reference to the inefficacy of the bromide to dispel said attacks of *petit mal*. I may make the same remark concerning the treatment of epileptic insanity.

(To be concluded.)

A CASE OF SUPPOSED PERIOSTITIS IN THE NEIGHBORHOOD OF THE FORAMEN MAGNUM.

BY FREDERICK P. HENRY, M.D.,

Philadelphia.

THE principal, although not the only, point of interest in the following case is the fact that the study of the mechanism of one of our commonest movements—that of nodding the head—was the only means by which the seat of the disorder could be ascertained.

T. H., æt. 30, driver of a street-car, came to the Catharine Street Dispensary on the 30th of January, 1872, complaining of a tingling sensation in both hands and arms, "as if they were asleep;" also of a feeling of weakness and numbness in both upper extremities. The tingling is not constant, but is at once produced by taking hold of anything, whether gently or with force. For example, in turning the brake of his car he feels it; he also feels it when he takes out his watch. He can produce it at any time by slightly bending his head forward, as in the act of nodding. This act, by the way, is performed when he looks at his watch, and probably is when he turns his brake; so that it is extremely doubtful whether, instead of ascribing the abnormal sensation to the contact of the foreign bodies, he should not have ascribed them to the accompanying motion of the head.

Occasionally he has momentary attacks of vertigo and dimness of sight, during which his face feels very hot. His appearance is that of a man in exuberant health. He stands erect and firmly on his legs. He has a fine color,—too much color, one would say *after hearing the symptoms*,—although it seems to have been habitual. His appetite is good; he sleeps well; he is neither fat nor lean, but well nourished, and, in fact, were it not for the symptoms detailed above, his physical condition would leave nothing to be desired.

On first seeing the patient, I had little time to bestow upon his case, but, perceiving it to be one of some interest, I determined not to lose sight of him.

I prescribed ten grains of the bromide of potassium three times a day, and two compound cathartic pills for three nights on going to bed.

February 5.—He has taken his medicine regularly, but the symptoms remain the same; he thinks, however, that he feels decidedly weaker. I prescribed iron and quinine,—somewhat empirically, it must be acknowledged,—ordered him to attend to the state of his bowels, and to take a hot foot-bath every night on going to bed.

February 13.—At this interview I examined the patient more carefully as to his previous history than I had done hitherto. I ascertained that in the month of June, 1871, he had a chancre situated upon the frænum præputii, followed by three non-suppurating buboes, two of which were situated in the right groin and one in the left. He received no constitutional treatment, but, to use his own words, he "burnt the chancre, and it soon got well." He has had no eruption upon the body, to his knowledge, no sore throat, and no rheumatic pains. His throat, on examination, appears perfectly healthy. There is an enlarged and indurated lymphatic gland upon the back of the neck, to the left of the median line and about one inch from the extremity of the left mastoid process.

At the last October elections (1871) he was wounded with a black-jack over the occipital bone: the scar is situated directly upon the nucha, and extends about an inch below it. After receiving the wound, he remained insensible for three hours. He feels stronger than when last seen, but the tingling sensation is still produced in all the fingers of both hands by slightly bending the head forward.

I made an ophthalmoscopic examination of the right eye, and found nothing abnormal. In the left eye there is an anterior synechia, caused by a prolapse of the iris from a corneal wound, giving the pupil a transversely elliptical shape. I did not examine the left eye, at the patient's request; he stated that it was "weak." I advised him to begin the use of the iodide of potassium; but he thought he had derived some benefit from the last prescription, a small quantity of which still remained, and wished to finish it, to which I agreed.

February 20.—About the same. If there is any change, it is for the worse. By careful examination I ascertained that the tingling occurs during the first stage of the act of nodding, viz., during the movement of the occipital bone upon the atlas. When the act proceeds farther, the tingling is increased. Ordered gr. x of potass. iodid. three times a day.

At this point a few words upon the act of nodding will not be out of place. This act is the product of a combined movement of the occipital bone upon the atlas, and of all the seven cervical vertebræ upon each other. It may, for our present purpose, be divided into two stages, the first stage consisting of the movement of the occipital bone upon the atlas, the second, of that of the cervical vertebræ upon each other. Let any one, preserving the cervical portion of the spine rigid, attempt to bend his head forward, and he will find that the motion—which is that of the occipital bone upon the atlas—is very limited. In order to the full performance of the act of nodding, it is necessary that the whole cervical portion of the spine participate in it. When this is done, the slight anterior convexity of the cervical region is abolished, and, the movement being carried still further, a slight concavity substituted, while the convexity is transferred to that portion of the spinal column which covers and protects the posterior columns of the cord.* The spine of the vertebra prominens, as well as the other cervical spines, becomes more prominent, as any one may observe by placing the hand firmly upon a cervical spine, and bending the head forward.

* The mechanism of this act (nodding) was tested upon a recent section of the cranium and cervical vertebral region.

In an article on "fractures of the odontoid process," by Dr. Stephen Smith, of New York (*Amer. Journal of the Med. Sciences* for Oct. 1871), a number of cases of that accident are detailed. In Case IV., in which there was caries of the atlas and axis, "pricking sensations were felt in the right superior extremity, and there was evidently a loss of muscular power in it." In Case V. there was "fracture of the axis in such a manner as to include the base of the process." It was "not till sixteen months after the accident" that the patient "complained of numbness and want of power in the left arm."

Now, in the case of T. H. a violent blow had been received upon the occipital bone. Cases XII. and XV. of Dr. Smith's article are cases of "fracture from violence applied to back of neck." Taking these facts into consideration;—to wit, that violence had been applied to the back of the neck, probably sufficient to fracture the odontoid process or the posterior arch of the atlas; that the patient had a syphilitic history, and that on bending the neck a tingling sensation was transmitted from the posterior columns of the cord along the brachial plexus to the nerves of the upper extremities and their terminal filaments,—taking these facts into consideration, I concluded that there was *some* lesion in the upper portion of the vertebral column, and I was led to localize that lesion either in the posterior border of the foramen magnum or in the posterior arch of the atlas, by finding that the disordered sensation occurred during the first stage of the act of nodding. What the nature of the lesion might be, I did not pretend to say, but considered it to be one of three things,—fracture, periostitis, or caries.

February 22.—T. H. states that he caught a violent cold on the evening of the 20th, since which he has not felt the tingling, and cannot produce it by nodding. Tried in vain to do so in my presence. Attributes the cure to rest from his ordinary occupation.

The violent cold of which the man complained was simply the effect of his medicine. It was a well-pronounced case of iodism.

I saw T. H. again on the 30th April, two months later. He had rested for several days before returning to his work, since which he had experienced no return of the symptoms that had formerly caused him so much anxiety.

Now, this favorable result of the case only serves to render the diagnosis still more difficult. If the tingling had been constant, I should attribute the disordered sensation to exhaustion of nerve-force in the upper extremities; but in that case the symptom ought to be common among car-drivers, and T. H. stated that he had not known any of his fellow-employés to suffer from it. It was *not* constant, however, being produced by bending the head forward; and I am forced to conclude that there was a slight degree of periostitis causing pressure upon the posterior columns of the cord at its commencement, during a certain movement of the head. The patient was one of those persons, of whom we see so many, peculiarly susceptible to the action of iodide of potassium, and a few doses of the drug were sufficient to cause absorption of the slight inflammatory thickening which had taken place.

NOTES OF HOSPITAL PRACTICE.

JEFFERSON MEDICAL COLLEGE.

SURGICAL CLINIC OF PROFESSOR S. D. GROSS, M.D.

Reported by FRANK WOODBURY.

A LARGE SARCOMATOUS TUMOR IN THE FACE.

THIS boy, who is unusually large and well developed for his age (fifteen years), comes to us from the interior of this State on account of a large tumor in the right cheek, which he first noticed about a year ago. Since then its size has been gradually and constantly increasing, although it is unattended by pain, and he states that his general health is excellent. It has grown so large as to materially interfere with the movement of the jaw, preventing him in a great degree from opening his mouth. It was supposed at first to arise from diseased teeth, and the molars of the lower jaw on the right side were extracted without influencing the morbid action, and the teeth were found to be perfectly sound.

The tumor is now prominent, firm, and resisting; its surface is uniformly smooth, and not tuberculated. The skin above it is apparently normal and not discolored, there are no large subcutaneous veins, and the submaxillary and cervical lymphatic glands are not enlarged or indurated. It seems to send a caudate process around and behind the ramus of the jaw-bone. Examined from the inside of the mouth, the tumor is found to lie immediately below the mucous membrane of the cheek, extending backward toward the tonsil. The gums and alveoli of the upper teeth seem natural. The tumor evidently protrudes into the nasal fossa, but has not encroached upon the orbit, as the eye is natural and not affected. The disease may have begun in the antrum and extended outward to the cheek, and inward, protruding the internal wall into the nasal fossa; or it may have commenced externally and secondarily invaded the antrum.

This is not encephaloid disease. Nor could it be easily mistaken for scirrhus, which is accompanied by sharp, shooting pain, grows slowly, and soon involves the overlying skin, making it discolored, glazed, and hard, like the rind of bacon. In both of these affections the lymphatic glands in the neighborhood would become involved and enlarged early in the disease. If this were an encephaloid disease of the antrum, which often occurs, there would be an increase in the size of the subcutaneous veins in the cheek, some of the teeth of the upper jaw would be displaced, and there would be more or less ulceration of the roof of the mouth, a condition of things which does not exist at all in the present case. This is not melanosis or colloid, but belongs, in all probability, to a class of tumors which have been well defined and described by Virchow, and by him designated *sarcoma*, which is now understood to comprise a variety of morbid growths that had previously been confounded with encephaloid.

Although this tumor is not, in the strict sense of the term, malignant, yet, by its bulk and rapid growth, it might readily threaten the patient's life by involving important structures. If it were allowed to remain, it would soon press upon the pharynx and seriously impair respiration and deglutition. The indication, therefore, is to remove it, and this should have been done long before it attained its present size. Part of it extends around among the vessels of the neck, greatly enhancing the danger of hemorrhage and the risk to the patient. These tumors should always be removed as early in the history of the disease as possible; no other treatment is of the slightest avail; the knife is the only effective remedy. It is true that the

tumor may, and probably will, return in six, twelve, or eighteen months, but in some cases it does not come back at all, and our patient is entitled to our best efforts to relieve him from the disease and to give him the chance of permanent recovery. He is young, which is a great point in his favor. The disease may recur either in the parts in the immediate neighborhood, or in some of the internal, vital organs, when it will be likely to prove rapidly fatal.

We will give the patient the benefit of the doubt, and, after he is fully under the influence of the chloroform, remove the tumor; but I am not so sanguine of the result of the operation as I should be if the disease had not attained such a strong foothold. The external incision is begun at the commissure of the mouth; we shall endeavor to enucleate the tumor and bring it away entire, if possible. The parts are very vascular, and the facial artery and several smaller vessels require the ligature. The adhesions to the bone are very strong. A large part of the mass extends around the bone toward the internal maxillary artery, deep in the fossa behind the jaw. I shall not use the knife here, but by grasping the tumor with the forceps and twisting them I have succeeded in extracting it by evulsion. The tumor is fibromatous in its appearance, and strongly resembles those which grow in the pharynx and nares, which are called fibroid polypi. The wound is large, and bleeds freely. To check the hemorrhage the wound shall be packed with cotton impregnated with Monsel's solution, which acts as a powerful styptic and antiseptic. He shall have an anodyne, as he may require it, once or twice a day, and, if he does not rest well, a full dose of morphia at night.

October 26.—(Three days after the operation.) The patient is doing well. He is able to swallow food, and the wound in the cheek is granulating. The tumor was examined microscopically and found to be a fibro-sarcoma containing numerous spindle-cells.

November 2.—The patient died this morning from exhaustion. He had several attacks of dyspnœa, and last evening, as he could not open his mouth and was breathing badly, I performed laryngotomy, opening the larynx through the crico-thyroid membrane and inserting a double canula. This seemed to give him marked relief, and he was comfortable until this morning, when he sank rapidly. At the post-mortem, made by Dr. Barton, another tumor was discovered hanging in the pharynx, which we were prevented from seeing during life on account of his inability to open the mouth sufficiently. This tumor is about the size of a pullet's egg, and was attached to the mucous membrane between the pterygoid and styloid processes, and explains the difficulty of breathing. Another smaller growth was found depending from the basilar process of the occipital bone. These tumors are of the same character as the one we removed, but evidently entirely disconnected with it, each being distinct. Had the operation been followed by perfect recovery, he would have ultimately perished from these coexisting tumors in the pharynx.

NECROSIS OF THE HUMERUS.

This boy, seven years of age, has disease of the shaft of the humerus, and has been here a number of times during the sixteen or seventeen months that it has troubled him. We have taken out small pieces of dead bone at various times, but did not find the necrosed portion sufficiently separated, or the involucrum strong enough to maintain the shape and usefulness of the arm after an operation.

We find the shoulder partially anchylosed, a fact which is owing probably to the extension of the inflammation up into the joint. To prevent this from becoming permanent, passive motion must be perseveringly employed until the function is fully restored. On the external aspect of the arm there is a raw surface, which is covered with exuberant granulations partly coated with pus; at the bottom of the ulcer a portion of dead bone is seen protruding. A smaller sinus exists on the front of the arm, lower down.

In giving chloroform, always see that the patient is in a recumbent posture, that his stomach is empty, and that there is no constriction of the clothes. The responsible office of administering the anæsthetic should only be intrusted to a perfectly trustworthy and experienced assistant, who thoroughly understands and exclusively attends to the business. With less precautions chloroform is a dangerous article, although I have used it in over four thousand cases without a single death, an immunity which I attribute to my extreme care in selecting a pure article, and caution in administering it. During the process, if there is a failure of the pulse or respiration, the chloroform should be immediately stopped and restorative measures instituted. The tongue should be pulled forward, with a tenaculum, away from the throat; and cold affusions to the face and chest, flagellation of the nates and extremities, and inhalation of ammonia should be resorted to at once. Should these prove ineffective, an injection may be given of ammonia, either alone or in combination with alcohol, pieces of ice may be inserted into the rectum, and our great restorative agent, electricity, should be employed. These are all valuable means of recovering a patient who has taken an overdose of this potent agent, and one or more of them has, in my hands, always proved successful.

The patient being well influenced, we will enlarge this opening down to the bone and remove the necrosed portion. We will then carefully scrape out the cavity to remove all the carious particles of bone and unhealthy granulations that would interfere with the reparative process. There is always considerable hemorrhage in these cases, because the capillary vessels are clogged with lymph, which prevents their contraction and retraction, and allows more blood to escape than if they were normal. With the bone-forceps we extend the opening in the involucrum, and, with the pliers, extract this large sequestrum, which represents the entire shaft of the humerus. This was caused by an inflammation of the endosteum and consequent death of the bone, by a morbid action of peculiar character, due to an inherited specific taint of the boy's system. New bone was subsequently deposited from the periosteum, forming an investment of living bone, which is termed the involucrum, and the enclosed portion, which afterwards separates, is named the sequestrum, or *sequester*, as I prefer to call it.

After the operation the margins of the openings leading down to the bone are trimmed off with the scissors, as they are unhealthy and interfere with repair. We then scrape the cavity to remove all the spoiled lymph and dead bone, being careful not to remove so much as to weaken the involucrum, lest it might give way, producing a troublesome fracture. The wound is then thoroughly washed out by a stream of water from a syringe, to remove the chips. If the bone should bleed much, as will happen occasionally, the wound should be plugged with styptic cotton.

An emollient poultice will be applied to the wound twice daily, and each time it is changed the cavity will be washed with warm water, to which a little Castile soap may be added if the discharge is offensive. Permanganate of potassa is not needed here. His diet should consist only of the most nourishing articles of food. As a tonic he will have quinine and iron, and a glass of milk-punch daily. After a short time we shall commence with the iodide of potassium, as a general alterant and to counteract the peculiar poison which

produced this disease. The shoulder and elbow joints will be moved every day.

October 19.—The patient is presented. The part secretes laudable pus, and the granulations are now healthy. Bony matter will soon be deposited and fill the cavity in the bone, making it stronger than ever. It will not be as smooth as its healthy counterpart on the opposite side, and the medullary canal will not be reproduced,—the bone always remaining heavier than its fellow.

INFANTILE PARALYSIS.

This little two-year-old, in walking, drags his right foot. His mother states that this condition has existed for two months, and came on suddenly without assignable cause. He was not teething at the time, but had a bad catarrh of the lungs and was very feverish and restless. He has no power whatever in the limb, which is manifestly lowered in temperature. The muscles of the leg, thigh, and buttock are remarkably flabby, and, as he stands before us, the affected limb is thrown outward and the foot is strongly everted. Please notice, that although there is entire loss of power in the limb and the muscles are wasted, yet the gluteo-femoral crease remains natural, and shows no marked difference as compared with the opposite side. In hip-joint disease this would not be the case, as this crease is effaced early in the disease. This is an important diagnostic symptom, and should be borne in mind.

This is a case of infantile paralysis. This affection generally comes on suddenly, during an attack of fever, cholera morbus, cholera infantum, or teething. The little patient will go to bed apparently well, perhaps a little feverish, he is restless and tosses all night, and in the morning when the mother comes to him she finds him unable to walk; he has lost the power of one or both of his legs. This attack may occur at any period of infantile life, but generally occurs toward the end of dentition, when the large molars are coming through. Both limbs are generally involved in the paralysis, but there is never palsy of the upper extremities, no matter how much exists in the lower. The lesion, then, is one existing in the spinal column low down, not in the brain or its meninges, but in the spinal cord near where the sacral plexus of nerves is given off. It is due to an inflammation of the theca, or of the substance of the cord; which is followed by deposition of the usual inflammatory products. The arachnoid membrane of the cord is continuous with that of the brain. It is a serous membrane, and, when inflamed, pours out serum in abundance, and if the morbid action continues there will be an effusion of lymph, plasma and fibrin. This gradually disappears as the child grows better; the absorbents quickly remove the serum and lymph which constricted the nerves, but some of the fibrin may remain and become organized, thus maintaining the paralysis. The tendency of fibrin to organization then teaches us, by prompt measures, to step in and induce the absorbents to carry it off before this occurs. These products press on the spinal cord and nerve-trunks originating at the seat of the morbid action, and interfere with the passage of the nerve-current to the parts which derive their supply from this portion of the spinal cord. If this pathology is correct, then, in this case the pressure must be limited to one side, and the entire spinal cord is not implicated. These are very interesting cases as respects their pathology, diagnosis, and treatment.

The diagnosis is not difficult. The affection comes on suddenly, in a single night, generally during teething. In coxalgia the disease is gradual in its onset; there is considerable pain, referred to the knee, far away from the seat of the disease. This limb can be moved freely in every direction, to a greater extent even than in health; but in disease of the hip-joint the muscles would be stiff, and moving the limb would produce severe pain; percussion of the heel would also be painful, which you see is not the case here. During the progress of coxalgia the hip becomes swollen and flattened, the gluteo-femoral crease disappears, and the buttock, hip, and thigh form a continuous plane surface. This child is well nourished; his appetite is good, and the digestive function well performed; but in the strumous disease the exact contrary would hold, and the child would be sick.

Be extremely guarded in your prognosis in these cases. Do everything in your power, but promise nothing. As a rule, the sooner treatment is instituted, local and constitutional, the better chance the patient has for recovery. When it has existed for several months, as in the present case, the paralysis is generally persistent. If you are called on the first day, if the child is weaned, you may give a mild laxative to moderate the inflammatory excitement. Over the lower half of the spine sorbefacient applications may be tried, or a blister applied. For the latter purpose cantharidal collodion is the best; but it should not be applied thickly on the delicate skin of an infant. Or, if the blistering ointment is used, it should be diluted with simple cerate, and should not remain on more than two hours at the farthest. The object is to excite the absorbent vessels so as to induce them to remove the effused fluids. Our efforts should not be directed exclusively to the part, but also to the system. About gr. $\frac{1}{4}$ to gr. $\frac{1}{2}$ of mercury with chalk, or blue-mass, may be given thrice in the twenty-four hours. We do not produce ptyalism in these cases, for fear of causing gangrene and sloughing of the cheek or jaw. It is given for the same purpose as when administered in a case of opaque cornea or enlarged testicle, to stimulate absorption. It should be given cautiously, and the patient frequently visited. One foreign leech, or the tincture of iodine, might be applied to the affected spot, but vesication is much better.

This case has become chronic; vesication would be without effect here. The spinal column shall be washed every morning with warm water and shampooed with the hand, then flagellated smartly with the end of a towel wrung out of cold water. This process should also be applied to the affected limb; it will produce reaction, quicken the circulation, and stimulate the muscles. We will give,—

℞ Tr. saponis camph., f℥ij;
Veratriæ, gr. x. M.

a small quantity of which is to be rubbed twice daily along the entire spinal column and along the sciatic and crural nerves of the affected limb. This may have to be continued for a year or eighteen months, in order to be effective. The diet should be plain and nutritious. He may take,—

℞ Potassii iodid., gr. $\frac{1}{3}$;
Hydrarg. chlorid. corros., gr. $\frac{1}{20}$. M.

thrice daily. This will act gradually on the lymph at the seat of the disease, which is the cause of the difficulty, and promote its absorption.

PROPORTIONING DOSES TO AGE.—On this subject the *American Practitioner* for Nov., 1872, quotes the rule proposed by Dr. R. O. Cowling in the first number of that journal. "The proportionate dose for any age under adult life is represented by the number of the following birthday divided by twenty-four: *i.e.*, for one year, $\frac{2}{24} = \frac{1}{12}$; for two years, $\frac{3}{24} = \frac{1}{8}$; for three years, $\frac{4}{24} = \frac{1}{6}$; for five years, $\frac{6}{24} = \frac{1}{4}$, etc." [See the *Philadelphia Medical Times* for November 9, 1872, p. 86, for the rules given by Gaubius, by Dr. Young, and by Dr. E. H. Clarke, of Boston.—ED.]

PHILADELPHIA
MEDICAL TIMES.
A WEEKLY JOURNAL OF
MEDICAL AND SURGICAL SCIENCE.

The Philadelphia Medical Times is an independent journal, devoted to no ends or interests whatever but those common to all who cultivate the science of medicine. Its columns are open to all those who wish to express their views on any subject coming within its legitimate sphere.

We invite contributions, reports of cases, notes and queries, medical news, and whatever may tend to increase the value of our pages.

All communications must bear the name of the sender (whether the name is to be published or not), and should be addressed to Editor Philadelphia Medical Times, care of the Publishers.

PUBLISHED EVERY SATURDAY BY
J. B. LIPPINCOTT & CO.,
715 and 717 Market St., Philadelphia, and 25 Bond St., New York.

SATURDAY, DECEMBER 7, 1872.

EDITORIAL.

TROUBLES IN NEW YORK.

THE Commissioners of Public Charities and Correction in the city of New York would seem themselves, if the statements in the daily papers of that city are to be relied upon, to need some correction. How they are appointed we do not know, but we presume by the Legislature; they are five in number, and have the control of hospitals and asylums containing four thousand one hundred and six beds.

On the 8th of November they summarily removed Dr. M. G. Echeverria, from whose contributions to our columns our readers can judge of his professional ability, from the post of resident physician to the Ward's Island Lunatic Asylum. The troubles which preceded and led to this action are detailed by Dr. E., in a communication to the mayor, occupying a column and a half in the New York *Times* of Nov. 26. This letter sets forth an extremely disgraceful state of affairs, against which its writer seems to have manfully but vainly protested. Some part of his own action, if we understand it rightly, was impolitic, although taken in all honesty and good faith; but the commissioners appear to have been entirely reckless of their duties, discourteous and overbearing to their medical officer, and obstinate in their refusal to carry out any suggestions for the reform of most glaring abuses. No wonder they wanted to get rid of Dr. Echeverria, who could not be made a tool or an accomplice in their maladministration of their trust. We are curious to see what defence they will set up against his telling charges.

In the Bloomingdale Reception Hospital the Board seem to have had physicians more of their own stamp. An affidavit is made by a young colored woman, taken there in an epileptic attack, to the effect that she was most cruelly and indecently treated. One of the commissioners, in answer to an inquiry, said, "We have approved the conduct of the physicians, and there's an end of it." Since, however, the attention of the Grand Jury was called to both institutions, and this body was to hold an investigation, we may hope for a result more satisfactory to the public. We have, as yet, seen no mention of any further disclosures, either for or against the commissioners.

"SCOTCHED, NOT KILLED."

WHEN the Pennsylvania Legislature revoked the charters of certain diploma-selling institutions in this city, on the 20th of March last, there were perhaps some of the simple-minded who thought that the trade was destroyed, and that those who had plied it would be driven either to honest occupations, or to some other branch of pocket-picking. One of these "colleges" has indeed ceased to exist as such, and, with a sort of grim humor, an "intelligence office" has been set up where its Dean used to carry on his nefarious traffic. The other, at 514 Pine Street, is in full blast, and an advertisement of it, on the same page with that of the Hahnemann Medical College of Chicago, in Braithwaite's Advertising Department, is now before us. Forty dollars is the sum demanded for a course of lectures in this seat of learning, which certainly seems cheap, as the homœopathic school charge eighty-five; but perhaps, the quality of the article furnished being taken into the account, even forty dollars would be too much.

We are also in receipt of a letter from Poitiers, in France, asking what is the value of the diplomas of this forty-dollar college, and saying, "It is true that this university has had his charter revoked by the General Council of Pennsylvania, and it is yet able to deliver degrees and diplomas."

Another letter, now also before us, will explain how and why this business of selling diplomas can be carried on. It is dated Hong Kong, Oct. 12, 1872, and reads as follows:—

"TO THE SECRETARY AND REGISTRAR, COLLEGE OF SURGEONS AND MEDICINE, PHILADELPHIA:

"SIR:—Being an English qualified medical practitioner, I have the honor to request you will grant me

an American diploma of medicine, in order that I may be enabled better to practise under the American flag. Satisfactory proof of my qualifications may be had, and the Oriental Bank will accept any draft at sight that may be necessary to draw to cover fee, expenses, etc.

"I am, sir,

"Yours obediently,

"JAMES WILKINSON, M.D., F.R.C.S."

So long as there are men who are willing to pay for diplomas irregularly obtained, there will always be men ready to furnish them. The above is only a sample of numerous similar applications we have seen. It is the demand which creates the supply; all that is necessary is to print the certificates and to sign them, and then to arrange for their transfer, which is a matter of no difficulty.

The only puzzle which remains is, how an institution, the charter of which has been revoked, can be maintained in full career, under the same name, and without any apparent change. Is a charter unnecessary? We believe the spleen has been occasionally removed from some of the lower animals, seemingly without harm; and perhaps a charter, in the lower forms of medical colleges, can be in like manner dispensed with. We cannot very well ask "Dr." Joseph Sites, the "Dean of the American University of Philadelphia," about this, but we wish he would tell us, if he knows.

ERRATA.—In the *Times* for November 23, 1872, No. 56, in Dr. Mitchell's lecture, the word "vasal" was twice wrongly printed "basal," in the second paragraph on p. 115.

Also, on p. 127, the Endowment Fund of the Hopkins Hospital in Baltimore was said to be $2,000,000. It should have been stated at $200,000.

PROCEEDINGS OF SOCIETIES.

PATHOLOGICAL SOCIETY OF PHILADELPHIA.

THURSDAY EVENING, OCTOBER 24, 1872.

THE PRESIDENT, DR. J. H. HUTCHINSON, in the chair.

DR. F. P. HENRY exhibited a *gall-bladder enormously distended by biliary calculi*, and read the following history:

M. K., æt. 68, female, single, was first seen by me on the 15th August, at which time she was suffering from abdominal pain and tenderness, most severe in the right hypochondriac region. There were no other symptoms, if we except a marked tendency to constipation. The lungs were sound, appetite good, and during the whole period of my attendance (upwards of two months) there was no nausea or vomiting. There was nothing to direct attention to the kidneys, but the urine was tested with heat and nitric acid, and found free from albumen. No abdominal tumor was discovered at this time, although palpation was made, but the tenderness was too great to admit of its being thoroughly performed. There was a good deal of tympanitis.

The pain was soon relieved by morphia and warm fomentations, and for several days the patient was quite comfortable, and able to walk about the house. The same symptoms returned, however, and continued to do so at varying intervals, the longest being about two weeks, the shortest two days, until the attack preceding her death.

I have made no note of the date at which I discovered a tumor in the right hypochondriac region, but think it was somewhat more than a month ago. This tumor, instead of aiding in the diagnosis, served rather to mislead. It was hard, very tender, and distinctly nodulated. I concluded that it was a cancerous tumor of the liver. Any one, by feeling the specimen, and reflecting that when I first felt the tumor the thick abdominal walls were interposed, will perceive how the sensation communicated to the hand was so modified as to lead to this error. The attacks of pain became more and more frequent, each one further reducing the strength of the patient, until the final one, which occurred on the 17th. It was controlled by the means which had always proved successful,—morphia in divided doses until half a grain had been taken,—but the patient did not rally. She gradually sank, retaining her faculties until within a few hours of her death, which occurred on the evening of the 20th. During the last two days of life there was a slight amount of jaundice.

The *post-mortem* examination, in which I was assisted by Dr. Nancrede, was made sixteen hours after death, the abdominal cavity alone being opened. The first object searched for was the tumor which had been felt during life, and which proved to be the gall-bladder distended with calculi. It was firmly adherent to the hepatic flexure of the colon, which rendered its removal somewhat difficult. The cystic duct was severed at its origin, and two calculi escaped, which, however, have been preserved. A portion of the liver was removed with the gall-bladder. The liver was rather small, its tissue soft, readily breaking down under the finger; and the bile-ducts were dilated in all directions. It was adherent by its upper surface to the diaphragm over the greater portion of the right tube. Under the microscope the hepatic cells were found to contain an abnormal quantity of oil-globules. The stomach, on its posterior surface, was covered with a number of punctated ecchymoses, and was quite empty. The kidneys were of natural size, and somewhat congested; the capsules were not adherent. There were a number of minute cysts covering the surface of both kidneys, the largest being about the size of a split pea. Under the microscope the uriniferous tubules appeared perfectly healthy. The bladder contained about an ounce of a fluid which had little resemblance to urine. It looked like beef-tea, and when allowed to stand deposited a substance exactly resembling shreds of beef; under the microscope this deposit was found to be composed of the epithelium of the bladder. The large intestine was filled with scybalous masses of a dark-brown color, and about the size of a walnut: several of these were examined, but no calculi were found.

In this case the paroxysms of pain were probably due to traction upon the adhesions existing between the gall-bladder and colon, rather than to the passage of calculi; the traction being caused by distention of the colon from flatus or fæces. I am led to this conclusion from the facts that relief invariably followed soon after the operation of an enema, that the jaundice

which would have occurred had there been obstruction of the common bile-duct was absent, and that there were no calculi in the intestines.

Dr. R. M. BERTOLET presented to the Society, for Dr. J. S. COHEN, *a larynx and trachea, with extensive tubercular ulceration in the former, necrosis of the right arytenoid cartilage, and multiple enchondromata of the tracheal rings.*

The main points of clinical interest in connection with the accompanying specimen, as kindly furnished to me by Dr. Cohen, are as follows:

The subject, a man forty years of age at the time of death, had complained during several years of an obscure pain at the left side of the larynx. Some three years ago occasional hoarseness occurred, and on two or three occasions a slight hemorrhage; the general health appearing intact. A laryngoscopic examination made at this time was negative, there being evidence of general congestion of the upper portion of the larynx only. On September 3, 1872, the patient was again submitted to laryngoscopic examination, in consequence of active disease of some five weeks' duration at the old seat of pain, which had gradually increased in severity, and was attended with paroxysmal cough, profuse expectoration, and great difficulty of swallowing. During the interval between these two examinations the general health had been good, up to the period mentioned, permitting the patient to attend to his business and work hard at it; but there had been occasional hoarseness, with more or less constancy of the localized pain. Physical exploration of the chest revealed only questionable impairment of respiratory murmur in the upper lobe of the left lung, attended with slight mucous râles, very much masked by the large mucous râles in the larynx.

Laryngoscopic inspection revealed a large circumscribed swelling of the left arytenoid cartilage, obstructing a view of the interior of the larynx. This was incised twice in rapid succession, producing a trifling hemorrhage followed by cough and expectoration, and attended with considerable relief to the local symptoms. No pus had been discharged, but the swelling seemed smaller, and deglutition became practicable. In a few days a discharge of pus occurred, followed by abatement of the local symptoms, and ability to swallow without difficulty. In the course of a week or two fresh symptoms of dysphagia supervened, compelling the exhibition of nourishment per rectum. The swelling, which had at no time completely subsided, was now distinctly acuminated, and was accompanied by moderate swelling of the opposite side. The vocal cords were apparently intact, but thickened; and no evidence of ulceration was visible about the epiglottis or in any portion of the larynx. Day by day this pointed swelling became more prominent, finally almost touching the epiglottis, and the patient declared he could feel it press the epiglottis whenever he made an attempt to swallow. It was the necrosed arytenoid cartilage working its way to the surface, but making little if any progress towards exfoliation.

Extensive infiltration of both lungs now supervened, followed by broncho-pneumonia, which terminated fatally in a few days, death occurring October 20.

Dissection, forty-three hours after death. The necrosed arytenoid cartilage was completely denuded, but firmly attached at its articulating surface, which had not apparently undergone any change; the vocal cord of that side, and the posterior portion of the ventricular band, had become obliterated by ulceration, and there was ulceration of the lower portion of the epiglottis on the same side. The trachea was intensely congested, but its mucous membrane was intact, save, here and there, evidences of the ulceration of a few glands. But the point of special interest was an irregular arrangement of hard nodules sprinkled over the anterior surface of the trachea, of cartilaginous or even bony consistence to the touch.

The lungs were disorganized throughout, and studded with small abscesses.

The patient was of a tuberculous family, several of whom had succumbed to ordinary phthisis.

The chief interest in the case, apart from the enchondromata upon the tracheal cartilages, is the prolonged evidence of laryngeal disease prior to involvement of the lung, and the rapid infiltration of the entire mass of the lungs so shortly before death.

Dr. COHEN had submitted the specimen for minute examination to Dr. Bertolet, who remarked that these cartilaginous tumors showed under the microscope the presence of hyaline cartilage, with interspersed points of ossification. It is worthy of note that these small outgrowths are mostly seated upon the centres of the tracheal rings, and do not spring from their upper or under margins, as is generally the case: in the latter site, by their union and subsequent ossification are formed those specimens of osseous tracheas to be found in almost every pathological museum.

The very minute size of nearly all these enchondromata, their yellowish-white color shining through the intact mucous covering, their aggregation into small groups, all lend a very deceptive appearance to this trachea, which in a superficial examination might easily be mistaken for caseous degeneration of miliary tubercle or of the mucous glands.

Tumors formed by enchondrosis of the laryngeal portion of the respiratory tract have been frequently observed, especially since the days of laryngoscopy, and in this situation they generally attain such dimensions as to imperatively demand operative interference.

Although great activity has of late years been manifested by laryngoscopists in discovering and studying new growths in the respiratory tract, I am not aware of a single case in which tracheal chondromata have been seen and diagnosed in this way. The insignificant size that they had attained in the present instance precluded the possibility of their detection during life.

Dr. BERTOLET also presented a *larynx and trachea removed from a tuberculous patient.*

The very extensive ulcerations of the ventricular bands and of the vocal cords have, in this specimen, almost entirely denuded the vocal processes of the arytenoids, which are seen projecting into the laryngeal cavity as white prominences. These cartilages have, in a remarkable manner, escaped any necrotic destruction, such as is frequently met with in cases of so-called "laryngeal phthisis."

The greatest amount of destruction has occurred at the three chief centres of the laryngeal mucous glands, the Morgagnian ventricles, ary-epiglottic folds, and the base of the epiglottis. Had this been a syphilitic process, we should not have found the tip of the epiglottis thus unaffected; it would have been more or less indurated and ulcerated, if not entirely destroyed.

The mucous membrane of the trachea is in a condition of catarrhal inflammation. Its mucous glands are filled with retained secretion that has undergone fatty degeneration, which can easily be emptied from their orifices by pressure.

In not a few glands this has already been accomplished during life by an ulcerative process. So that we find the mucous membrane studded with numerous small circular ulcers, having a muddy yellow base and sharply defined edges.

The most careful microscopic examination of the infiltrated zones of these ulcers and of the adjacent tissues failed to reveal the presence of any deposits in them of miliary tubercle.

It is still a mooted question among pathologists whether or not the presence of tubercles is the initial point of laryngeal ulcerations. There are certainly no traces of the tubercular element in this case.

PHILADELPHIA COUNTY MEDICAL SOCIETY.

Dr. J. G. STETLER, VICE-PRESIDENT, in the chair.

AT a conversational meeting held October 23, 1872, at 8 o'clock P.M.,

Dr. J. S. ESHLEMAN presented one of his patients, a case of united fracture of the tibia.

The family doctor being absent when the accident occurred, he was called upon to adjust the fracture. The line of fracture is transverse, and within an inch of the lower extremity of the bone; it was caused by the wheel of a cart. It was with difficulty that any displacement could be produced, or crepitation elicited, but, the patient being put under the influence of an anæsthetic, both were satisfactorily obtained, to which Dr. E. called the attention of two surgeons present and assisting at the time. The limb was adjusted in the fracture-box, and the family told to have their physician take charge of the case on his arrival. This is the last Dr. E. saw of the case. The family physician, his assistant, and the boy's father, state that the boy disengaged his limb and commenced hobbling about in the house during the third week, and walked the streets during the fourth week. I met him out and walking well in the fifth week. As the existence of a fracture in this case is doubted, I submit it for the examination of the surgeons present.

Is there a form of union by "first intention" in bone under favorable circumstances?

Dr. J. G. STETLER stated that the boy G. M., æt. 10 years, presented by Dr. E., was treated by Dr. Newcomet and himself, after the first dressing. He had been the family physician for some years. When he arrived, several hours after the accident, he found the leg placed neatly in the fracture-box. As the boy was very comfortable, the dressing was not disturbed. This was June 6, 1872. He saw the patient again on the 7th, 8th, 10th, 13th, 17th, and 23d. After the subsidence of the swelling, he examined carefully the supposed fracture, and came to the decided conclusion that the bones could not have been broken, as the union seemed complete. This was on the 23d, *and, to gain time*, he replaced the limb in the box, and permitted it to remain until the 29th. The dressing was entirely removed, and the patient allowed to sit at the window. Not being satisfied with this, the lad in a day or two began to move about the house, and went out on the Fourth of July. He mentioned that there was no extension or counter-extension in this case. He believed fully that the boy could have walked as well on the seventeenth day after the accident as he did on the twenty-eighth.

Could there have been a fracture with complete union on the seventeenth day? He and Dr. N. thought it impossible.

Dr. WASHINGTON L. ATLEE thought there must have been a fracture, from the amount of callus which had evidently been thrown out.

Dr. W. B. ATKINSON asked Dr. Atlee if he had employed the starch bandage as modified by Dr. Peck, of Iowa, and explained by him at the Surgical Section of the American Medical Association (see vol. xxiii. p. 563 *et seq.*).

The views expressed by Dr. P. appeared sound, and in the opinion of Dr. A. this modification merited the attention of the profession.

Dr. M. O'HARA called the attention of the meeting to the present "epizootic" among horses.

Dr. J. SOLIS COHEN remarked that the use of sulphurous acid, by fumigation, inhalation, and internal administration, might be profitably employed as a cure or preventive. Sulphur or the hyposulphites could be administered internally, and sulphurous acid be used by inhalation, either from sulphurous acid water of the British Pharmacopœia, or from the fumes of burning sulphur; while the sulphurous acid fumes from burning sulphur could be employed from time to time to fumigate and disinfect the stables. From analogy, he would expect more benefit from sulphurous acid than from any other agent.

Dr. A. G. B. HINKLE exhibited the fragments of a large nipple-shell, which he had removed from the vagina of a patient over eighty years of age, who had worn it as a pessary for more than four years. The removal of it was attended with considerable difficulty, as it resulted in fracture of the glass, and considerable cutting of the parts, as well as of the fingers of the operator.

The mode of removal was by passing a wire hook into the central aperture of the shell, with the forefinger of the right hand introduced as far up as possible upon the convex surface of the same, while gentle traction was attempted with the left hand. The glass yielded to the force of traction, and the operation was completed by removal of the fragments with the fingers. The patient made a good recovery.

Dr. W. L. ATLEE suggested that by introducing the finger into the rectum the removal might have been facilitated.

Dr. WILLIAM GOODELL remarked that he was once compelled to use the knife in extracting a ring pessary. For two years it had not been removed from the vagina, and at the end of that time fully one-half of it had become imbedded in the walls of the vagina, through the arching over and union of the granulations produced by pressure.

GLEANINGS FROM OUR EXCHANGES.

ON THE SEQUESTRATION OF ALLEGED LUNATICS.—In the *Journal of Psychological Medicine* (New York) for July, 1872, there is a valuable article on this subject by Dr. R. W. Parsons, Superintendent of the New York City Lunatic Asylum.

The question lies between the avoidance of needless irritation and annoyance to the patient, and obstructions to the early adoption of hospital care and treatment, and the providing of safeguards against the confinement of sane persons by mistake or intention.

Against submitting cases of alleged lunacy to investigation by jury are urged: 1, the inefficiency of the method; 2, the delays, annoyances, and publicity involved in it; 3, the opposition of friends, leading to neglect of needful restraint.

Some superintendents think patients should be taken to asylums just as the sick are to general hospitals.

A middle course is prescribed by the laws of the State of New York, two respectable physicians examining the patient and making affidavit of his insanity before a magistrate, who thereupon commits the person in due legal form, retaining the affidavits as his vouchers. [In Pennsylvania the physicians merely make the affidavits, which are endorsed by a form signed by the magistrate.] Practically this is open to some objections.

"Since the year 1847, no less than one hundred and twenty-five persons who have been committed to the New York City Lunatic Asylum as insane have been discharged as improper subjects. During a single year

forty persons have been discharged from American asylums as having been *not insane* at the time of their admission. Many such cases are admitted every year."

Among the mistaken conditions are: delirium of fever, intoxication, acute cerebral congestion or inflammation, debility, eccentricity, imbecility, senility, feigned insanity; cases are sometimes wrongly diagnosed through ignorance, want of care, too great reliance on the statements of others, and faulty methods of investigation. Transient mania has sometimes been wrongly thought to require commitment to an asylum.

Dr. Parsons adduces eleven illustrative cases, among them that of Miss Montez, so much talked of a few years ago in the daily papers. He comments upon the vague interpretation of the term *dangerous*, which by the laws of New York the examining physicians must consider applicable to the patient in making out their affidavits.

He thinks the examinations should be made by the physicians separately and independently, more than one visit being made if necessary. It must, of course, be upon his own personal observation that each one acts.

Information can be obtained from others as to the character and duration of the insanity, and the habits and conduct of the patient. Sometimes it is better that this should precede the personal examination. The motives of witnesses,—such as revenge, hatred, desire to get rid of trouble, avarice, the desire to put away inconvenient testimony, etc.; or of the patient,—to escape punishment for crime, to evade pecuniary liability or disadvantageous contracts, or to secure a comfortable home,—must be considered.

The examining physician must act not on a mere vague impression, but should be able to give the reasons for his belief in such terms as would be intelligible and convincing to other intelligent physicians. All his facts should be reduced to writing at once, distinction being made between those derived from his own observation and those based on the testimony of others.

These statements should be transmitted, with the patient, to the asylum, being important guides, sometimes, even to the identification of the proper person to be detained.

It is highly desirable that the examining physician should be aware of the circumstances relating to the patient's mental and physical condition for a short time previous to his commitment.

Dr. Parsons proposes that blank forms should be employed, in four divisions: 1, a personal description to mark the identity of the patient; 2, the facts in the case, as observed by the examining physician; 3, the statements of other parties to him; 4, the actual state of the patient.

The question arises whether these examinations, investigations, and affidavits should be made by general practitioners as at present, or by experts authorized by law to attend to this duty. Dr. Parsons favors the present method, and gives strong reasons for this view. He justly advocates the more thorough teaching of the subject of mental diseases in medical schools.

Two classes of cases are not now satisfactorily provided for: 1, criminal lunatics, or such as in any way become the subjects of legal investigation: 2, those in whom no evidence of insanity could be detected by the examining physicians, but who are believed by unprofessional observers to be mentally unsound. Dr. Parsons is inclined to think well of the appointment, in such cases, of courts of inquiry, composed of men thoroughly informed on the matter of insanity; these courts or commissions being clothed, in their peculiar province, with the powers and privileges of other courts.

The Vienna Association for Psychiatry and Forensic Psychology met on the 26th of October, the Vice-President, Dr. Leidesdorf, presiding. The death of Dr. Spurzheim, the late President, was announced, and a eulogy of his character delivered by Dr. Gauster.

A discussion followed upon the mode of dealing with the dangerous forms of insanity, especially as intercurrent upon other diseases, Drs. Beer, Leidesdorf, Flechner, Meynert, Schlager, and Maresch taking part. The matter of the sequestration of such patients, with the reasons for so doing, and the protection of the physicians assuming the responsibility, was referred to a committee consisting of Drs. Maresch, Meynert, and Gauster, to be further reported upon.

The Dangers of Operations on the Neck of the Uterus.—M. Alph. Leteinturier (*Archives Générales de Médecine*) draws the following conclusions from his observations:

1. Operations (even when slight) upon the neck of the uterus may prove the *point de départ* of serious affections.

2. In such cases, more or less ancient lesion of the uterine annexes is discoverable. The operation seems, so to speak, to awaken the old inflammation.

3. Three circumstances may be referred to as favoring and explaining this: 1, a partial lymphangitis, commencing at and spreading from the neck of the uterus; 2, general congestion of the pelvic organs; 3, a congestion localized in some part of the genital system, occasioned by a reflex action originating in the cervix.

Amyloid Degeneration.—It is well known that amyloid degeneration is very common after long-continued suppurations, especially of bones and joints. But Professor Cohnheim (*Virchow's Archiv*, vol. liv. pts. 1 and 2) gives three cases in which it was found after a suppuration of joints of only some months' duration. The suppurations occurred in healthy men from wounds received in battle. The spleen was affected in all the three, and the kidney in one, so that the amyloid degeneration was in an early stage. The author has no doubt that the degeneration was the result of the suppuration, and the cases are remarkable on account of its occurring after such a short period.

Repeated Smallpox. — The *Boston Medical and Surgical Journal* says that a woman recently died in Boston of smallpox who had, only twelve weeks previously, recovered from an attack of the same disease. In the first instance, she gave the disease to several others in the family; in the second, it took on the hemorrhagic form.

Not many months ago a child, not over a year old, died in Boston of a well-authenticated second attack of smallpox.

These cases show that recurrence depends upon individual susceptibility, and not on the length of the interval between the two exposures to contagion. In other words, it is not a "wearing out" of protection that causes the second attack.

Electrolysis.—In the number of this journal for September 2, 1872, there was given an abstract of the first part of Drs. Beard and Rockwell's paper on electrolysis (*Medical Record*, July 15). The following additional cases are published in the *Medical Record* for October 18.

Case XIV.—Mrs. P. Recurrent fibroid tumor under the ear, the size of the closed fist. The growth appeared ten years before, and was entirely painless. It had been twice extirpated. Several external applica-

tions of galvanism were made without reducing the size of the growth, but enabling the head to be moved more freely. Twelve electrolytic applications were then made by introducing a single needle into the tumor, and in two months there was marked diminution in its size. After each operation a large amount of hydrogen gas escaped through the opening made by the needle.

Two needles were now used. The cells were increased from twelve to twenty, and the needles left in for fifteen minutes. There was great swelling and pain after this operation, followed by a discharge which lasted two months and caused a further reduction in the growth. During the next six or eight months the treatment was continued, and the tumor is said to have decreased in size gradually until it had reached one-third its original bulk.

Case XV.—Cystic tumor of the submaxillary region, the size of a walnut. After the first operation there was considerable sloughing, but the tumor was no smaller. The second operation was done by "working up the base." This appears to consist in passing needles connected with both electrodes between the diseased and the healthy tissue. The tumor seemed to be entirely removed after this treatment, but subsequently a growth the size of a horse-chestnut reappeared in the same locality. This was enucleated by Dr. Crosby, and the base electrolyzed. The wound healed rapidly, leaving but slight deformity, and the cure seems to have been permanent.

(In this case it is hard to say how much of the successful result was due to electrolysis. In the second and third operations the growth was removed by the knife before the application of galvanism, and in the ulcer which remained—one and a half inch in length and half an inch in depth—the edges had to be brought together to hasten union.)

Case XVI.—Epithelioma of upper lip. Very painful. Three needles connected with the negative, and two with the positive pole, were introduced into the tumor. Sixteen zinc carbon cells were used. The operation was performed twice, with the result of the entire removal of the growth and leaving but slight cicatrices. No return of the disease after one year.

Case XVII.—Scirrhus of the breast. Four needles connected with the negative pole were inserted into the breast; the positive pole—a large sponge—being placed under the gland. The pain, which had been intense, was immediately relieved, and in a week the tumor had decreased to one-half its original size. The same operation was repeated in ten days, but the patient left the hospital on the next day, and, unfortunately, has been lost sight of.

Case XVIII.—Scirrhus of breast. Pain greatly relieved by external galvanism, but no alteration in size from electrolyzation with a very powerful current.

Case XIX.—Scirrhus of breast. In this case the terrible pain was at first very much mitigated by the use of the induced current, and afterwards still more relieved by the external use of galvanism. After three operations by electrolysis the greater part of the tumor sloughed off, and the patient seemed relieved of pain, but finally died of exhaustion.

Case XX.—Epithelial cancer of vagina, rectum, and external parts. After eleven electrolytic operations the growths, one of which was half as large as a cauliflower, and protruded from the vulva, were removed. The extreme pain was alleviated, but the disease subsequently returned, though with less rapidity.

In this case, the authors note the value and limitations of electrolysis in malignant tumors, and point out: 1. Its power to control hemorrhage. The growth was so vascular that it bled on the least touch, but in all the electrolytic operations but little blood was lost. 2. No shock was caused by electrolysis. 3. Better healing, and more tardy reappearance of the growth, than after the ligature or other means which had been applied. 4. The severe irritative fever that sometimes follows this operation. 5. The utter inability of even the most thorough electrolyzations to eradicate the growth in those parts where it was *connected with the mucous membrane*.

Bronchocele.—Dr. Fenwick (*Canada Medical and Surgical Journal*, Nov. 1872) publishes a report read before the Medico-Chirurgical Society of Montreal, Oct. 19, of a case of fibro-cystic bronchocele operated on by him with success. The tumor was a very large one, consisting of three lobes, and had existed eighteen years, not having increased for four years past; the patient was a Canadian woman, aged 21. Dr. F. made his incision in the median line, divided the fascia covering the mass, and then enucleated the latter. Very profuse hemorrhage occurred, but was controlled. The patient rallied well from a condition of prostration which followed, and on the fifty-first day from the operation she left the hospital with the wound closed.

Dr. F. thought that in any future similar case he would operate somewhat differently, dissecting beneath the whole mass first.

Much difference of opinion seems to have prevailed in the society as to the propriety of such an operative interference.

[We saw about eighteen months since a very similar case operated on with success by Dr. Maury at the Philadelphia Almshouse Hospital. See the *Photographic Review of Medicine and Surgery*, vol. ii. p. 17.]

The Pathology of Stammering (Dr. Raffaello Coen, *Wiener Mediz. Presse*, No. 33, 1872).—This author gives the following summary of causes producing stammering:

The pathological cause of stammering is not a primary manifestation (the view hitherto maintained by other authors), but a secondary manifestation, produced chiefly by an anomalous pause in breathing, or by any other pathological condition of the organism. The fundamental condition of its existence is characterized as a central affection of the medulla oblongata, or as a spinal irritation, or as a combination of both pathological conditions. The exciting causes are anger, rage, anxiety, etc., but especially sudden and severe irritation of the nervous system, as, for example, increased excitability of the spinal cord from inflammation, pressure, etc.

The treatment consists of systematic "lung gymnastics" (forcible inspiration and expiration), and electricity (galvanization or faradization of the phrenic nerve and fibres of the cervical plexus, supplying the muscles of expiration), accompanied in many cases by the general hydropathic treatment and the "Swedish movement-cure."

Successful Tracheotomy in Membranous Croup.—Dr. W. I. Royster reports (Trans. Med. Soc. of North Carolina for 1872) a case which occurred in his practice in January, 1872, in which, on the fourth day of membranous formation in the larynx of a boy aged four years, the trachea was opened by Dr. E. B. Haywood. "The tube provided for the occasion was too large to be inserted; the opening into the windpipe was therefore well dilated with forceps, and the wound left open." The inhalation of steam was kept up, and a temperature of over 90° Fahr. maintained in the room. Four days after the operation the wound closed by granulation, and breathing through the natural passages was resumed.

MISCELLANY.

Congress of the German Surgical Association, 1872.—The proceedings at this meeting, which commenced on April 10, at Berlin, and was presided over by Prof. Von Langenbeck, have attracted, it seems to us, very little attention. Professor Von Bruns, of Tübingen, was elected Vice-President; Professors Gurlt, of Berlin, and Volkmann, of Halle, Secretaries; Dr. Trendelenburg, of Berlin, Treasurer. In addition, Billroth, of Vienna, Bardeleben, of Berlin, Simon, of Heidelberg, and Baum, of Göttingen, were elected into the committee. It was decided to meet every year at Berlin, on some day betwixt the 10th and 13th of April. Every one practising surgery is eligible for election. One hundred and ten members were present. The first paper was by Volkmann, on "Comparative Statistics of Injuries occurring in Time of Peace and War." He considered that better results were obtained in war times, in spite of the disadvantageous circumstances under which operations had often to be performed, since the soldiers were picked, healthy men. Professor Busch read a paper on "the Epitheliomatous Form of Lupus of the Extremities." Schede, of Halle, on the "Minute Appearances of Tissues after the Application of Tincture of Iodine." At the second sitting, on the 11th, a paper by Prof. Roser, of Marburg, was read on the "Fungus Micrococcus as the supposed originating cause of Pyæmia." Dr. Trendelenburg then related a case of "Stricture of the Trachea," in which tracheotomy had been performed and the stricture afterwards dilated with bougies. He also showed a "tampon" for stopping the trachea in operations on the jaws, tracheotomy being performed, and an india-rubber balloon carried in by a canula and then blown up so as to fill the trachea and prevent blood running into the bronchi. Stilling, of Cassel, read a paper on the "Pathogenesis of Urethral Stricture and the Histology of the Human Urethra," and Metzler, of Darmstadt, one on "Resection of Knee-Joint." At the third sitting, on the 12th, Busch, of Berlin, read a paper on the "Treatment of Fractures of the Skull with Depression," founded on six cases. Mühlvenzl, of Vienna, showed a field-stretcher and ambulance-wagon, as used in Austria. Bidder, of Halle, read a paper on "Treatment of Simple Fracture of the Femur without Restrictive Bandages." Dr. Wegner, of Berlin, a paper on "the Effects of Phosphorus on the Bony System." At the fourth sitting, on the 13th, Wolff, of Berlin, exhibited preparations illustrating the growth of bone. Surgeon-General Löffler made a communication on knee-joint resections. Simon contributed a paper "On a Method of Artificial Dilatation of the Rectum," in which he advocated scraping out carcinoma from the sigmoid flexure. Danzel, of Hamburg, gave some "Surgical Experiences in the Mariæn Hospital of Hamburg." Heine, of Innsbruck, read a communication "On the Diffusion of Tumors by Parenchymatous Injections." Adelmann, of Berlin, gave a case of "Swallowed Fork, removed by gastrotomy." The operation was quite successful, but the patient died a month after, of some other affection. Professor Uhde, of Brunswick, reported several cases of transfusion of blood. Professor Von Langenbeck had prepared a paper "On the Treatment of Gunshot Wounds of Joints," which was not read, for want of time.

At the Third Convention of the Teaching Colleges of Pharmacy of the United States, in September last, the following resolutions were passed unanimously:

Resolved, That this Convention regards analytical chemistry as essential for a thorough pharmaceutical education.

Resolved, That this Convention considers lectures on and practical instruction in qualitative analysis as very desirable for second-course students.

Resolved, That the Colleges of Pharmacy be requested to communicate the questions propounded for written answers in the annual examinations to all other colleges of pharmacy in the United States.

Resolved, That this Convention considers the establishment of the degree of Master in Pharmacy as desirable to be conferred upon graduates in pharmacy of not less than three years' professional service, who shall have passed another more stringent examination than "graduates" receive.

Resolved, That the degree of Doctor in Pharmacy should be a purely honorary one, to be conferred only upon pharmacists who have distinguished themselves in the advancement of the science of pharmacy.

Resolved, That the Colleges of Pharmacy are requested to annually report through their delegates to this Convention the names of those upon whom their honorary degree has been bestowed.

In the *Edinburgh Review* for October is an article on the "Progress of Medicine and Surgery," which contains, among other things, an account of the use of anæsthetics in surgery. In one of its introductory passages a statement occurs which would be ludicrous if it were not so seriously untrue. "As early as 1800," says the writer, "Sir Humphry Davy suggested the use of nitrous oxide gas, and indeed it was used in dental surgery by Dr. Evans, in Paris; by Dr. Horace Wells, in Halifax, United States, (*sic!*) in 1844. Sulphuric ether was also employed at Boston in 1846; but these agents were either so disagreeable in their odor, or so inapplicable to the major operations in surgery, owing to their want of persistency, that they had no chance of establishing themselves as permanent agents in the annihilation of human suffering, etc." And that is all the writer appears to know about ether and nitrous oxide! It is not often that the ponderous dulness even of the *Edinburgh Review* blunders into such a quagmire of ignorance as this.

University of Munich.—Dr. Francis Dowling writes from Munich to *The Clinic* that the four hundredth anniversary of this University was recently celebrated with pomp. Delegations were present from

all the Universities in Germany and Austria, also from Oxford, England. The corps of medical Professors will compare favorably with any in Germany. Profs. Pettenkofer, Siebold, Bischoff, Nussbaum, and Liebig lecture there. The hospital is old and badly ventilated, in consequence of which about *one-sixth* of the cases operated upon in the institution die of pyæmia. The clinics are poorly arranged, although there is plenty of material.

California College of Pharmacy.—This institution was incorporated on the 7th of August last, with a capital stock of one hundred thousand dollars, divided into one thousand shares of one hundred dollars each. It is to be located in San Francisco, and lectures were to be begun on the 1st of October. It has been determined by the management to grant a scholarship to the holder of each share of the capital stock, which shall cover all fees attendant upon a course of two seasons, except that of graduation, and which shall be available at any time within one year from the date of issue of said share.

The Centennial Exposition.—The following gentlemen have been appointed the subscription committee for the medical profession, under the authority of the Citizens' Committee on Finance of the Centennial Celebration:

Dr. John B. Biddle, *Chairman;* Drs. Francis Gurney Smith, John Neill, Caspar Wister, and Edward Hartshorne.

Le Mouvement Médical of October 26 announces that on the 19th the Council of War had condemned to death M. Regnard, a former *interne* of the hospitals of Paris, who had acted as general secretary of the prefecture of police during the Commune. Dr. R. was implicated in the execution of a man named Largillière, shot in the Rue Haxo on the 26th of May, 1871.

Compensation of Expert Medical Witnesses.—Dr. E. B. Haywood, being summoned as a medical expert to testify in a case of rape before a criminal court in North Carolina, and having so testified, presented a bill of ten dollars for his services. The claim being disallowed, Dr. H. appealed to the supreme court, and obtained a judgment in his favor.

The *New York Medical Record* wishes to correct the statement, which is going the rounds of the journals, that Dr. T. G. Thomas has resigned the chair of Obstetrics in the College of Physicians and Surgeons, N.Y. Dr. McLane was elected *Adjunct* Professor merely.

The Board of Health of Washington, D.C., have recently made a report, from which it appears that the number of cases of smallpox in that city from January 1, 1872, to November 1, 1872, was 512; the deaths being 111, or over 21 per cent.

At the last half-yearly meeting of the Scottish Meteorological Society it was announced that the Marquis of Tweeddale had presented the Council with £100 for the prosecution of an inquiry into the properties of ozone.

The author of the "Origin of Species" will, it is said, be brought forward as a candidate for the post of Lord Rector of Aberdeen University at the next election.

Under the will of the late Sir David Baxter, the University of Edinburgh becomes entitled to £40,000 for its further extension and endowment.

The freedom of the city of Bologna has been conferred upon Professor Virchow, "on account of the eminent services he has rendered to science."

Mortality of Philadelphia.—The interments reported at the Health Office for the week ending Nov. 30, 1872, were 261; 143 adults, and 118 minors. 16 were of bodies brought from the country; making the mortality of the city 245. Among the causes of death were:

Consumption of the Lungs	50
Other Diseases of the Respiratory Organs	49
Diseases of the Circulatory Apparatus	14
Diseases of the Brain and Nervous System	33
Diseases of the Digestive Apparatus	17
Zymotic Diseases (2 from Smallpox)	9
Typhoid Fever	5
Casualties	7
Cancer	2
Debility (including "Inanition" and "Marasmus")	30
Still-born	20
Old Age	9

(The interments reported for the week ending Dec. 2, 1871, were 508.)

The meteorological record kept at the Pennsylvania Hospital was as follows:

	THERMOMETER. Max.	Min.	BAROMETER. (2 P.M.)
Nov. 24	47.0°	35.5°	30.35 in.
" 25	52.0	39.5	30.12 in.
" 26	43.0	40.5	30.13 in. (Rain.)
" 27	41.5	34.0	30.31 in.
" 28	35.0	27.0	30.35 in.
" 29	30.0	18.0	30.04 in. (Snow.)
" 30	25.0	15.0	30.10 in.

Mean temperature of November, 1872, 41.26°; of November, 1871, 41.0°.

OFFICIAL LIST

OF CHANGES OF STATIONS AND DUTIES OF OFFICERS OF THE MEDICAL DEPARTMENT U. S. ARMY, FROM NOVEMBER 19, 1872, TO NOVEMBER 25, 1872, INCLUSIVE.

Randolph, Jno. F., Surgeon.—Assigned to duty as Post-Surgeon at Omaha Barracks, Nebraska. S. O. 204, Department of the Platte, Nov. 16, 1872.

Meacham, F., Assistant-Surgeon.—Assigned to duty as Post-Surgeon at Sidney Barracks, Nebraska. S. O. 204, c. s., Department of the Platte.

Heizman, C. L., Assistant-Surgeon.—Relieved from duty at Sidney Barracks, and assigned to duty at Omaha Barracks, Nebraska. S. O. 204, c. s., Department of the Platte.

Matthews, Washington, Assistant-Surgeon.—To report in person to the Commanding General, Department of the East, for assignment to duty. S. O. 297, Headquarters of the Army, A. G. O., Nov. 20, 1872.

King, W. H., Assistant-Surgeon.—Leave of absence extended thirty days. S. O. 106, Military Division of the Missouri, Nov. 21, 1872.

SATURDAY, DECEMBER 14, 1872.

ORIGINAL LECTURES.

CLINICAL LECTURES

ON PROLAPSE OF THE WOMB.

BY WILLIAM GOODELL, M.D.,

Physician-in-Charge of the Preston Retreat; Clinical Lecturer on the Diseases of Women and Children in the University of Pennsylvania.

LECTURE II.

(Continued from page 147.)

THE conjunction of the theory of *traction* with that of *ductility*—traction from the prolapsing vagina and bladder; ductility from a chronic congestion of the womb—thus offers a very reasonable explanation of the phenomenon of uterine elongation. It also accounts for the eversion of the lips of the os externum and for the circular hypertrophy of the glandular portion of the cervix. By the attenuation of the mechanically elongated part, and by the constant dragging of the vagina and bladder upon their belt of attachment, the veins of this presumedly non-involuted or otherwise softened structure—and more especially the veins below the os internum—are unduly constringed, and their circulation is, therefore, rendered sluggish. Through the stasis thus induced, the whole cervix, but principally its glandular portion, gains an excess of nutrition. The papillæ and capillary loops of the arbor vitæ become turgid; the sub-mucous layer of the cervical canal grows exuberantly from within outwards, and by rolling out makes the flaccid lips of the os gape open. By the tertiary accidents of friction against the sacrum, of exposure to atmospheric action, and of irritation from the dribbling urine, the mucous coat of the cervix becomes thickened and changed in structure. Thus is brought about that circular hypertrophy which intensifies all the other symptoms.

It is a vicious circle throughout: the prolapsing organ—say the vagina—tugs at the bladder, which yields, and in turn lends its weight towards the further descent of the former; by alternately coercing and being coerced, their united action at last begets the circular hypertrophy of the cervix; the latter returns the favor by edging and nudging on the vagina, which responds by still more increasing the prolapse of the bladder and the hypertrophy of the cervix, and by aiding them in drawing out the supra-glandular portion of the cervix. Thus this reciprocation is kept up until the constantly elongating and growing cervix has attained length and weight enough to act aggressively. Aided now by the downward succussions communicated to it by the movements of the body, it completes the work by wholly inverting the vagina. The resistance of the vaginal tube to this final extrusion, being spent upon its cervical attachment, pulls the already gaping lips of the os still more apart, makes the cervical canal funnel-shaped, and sometimes everts it so completely as to convert the internal os into an external one.

From this point of view, the condition of the cervix in any given case of prolapse determines the nature of the disturbing cause. If the uterine cavity is barely or not at all lengthened out, as in the simple descent of the womb, we may infer that the prolapse of the womb has been the initial event. If, however, marked elongation of the cervix is present, then the vagina and bladder have been the primarily prolapsed organs. Thus defined, the latter affection is essentially a prolapse of the vagina and bladder, and not of the womb; whereas the former is as essentially a prolapse of the womb. I beg you, however, not to regard this interpretation as final or authoritative. Pressed to the quick it may show flaws, and I therefore invite you to accept it simply as one more flexible than any other yet advanced. The truth is perhaps not yet reached, for nature transgresses by anonymous agents, whose ways are often past finding out.

We must now put our theories to test, in order to see whether they can be clinically sustained. Like our former patient, this one has also reached that period of life when senile atrophy of the reproductive organs begins to take place. The vagina, having lost its pelvic packing of fat, tends to sag down. This tendency is urged on by her occupation as a laundress, which compels the erect posture and much lifting of heavy weights. In one of her numerous confinements the perineum has sustained injury. The rent has not only deprived the vagina of its chief abutment, but has also straightened out and shortened its natural curve, making its axis coincide very nearly with that of the superior strait. The anterior wall of the vagina, being now unsupported, began to bulge downward. During gestation the vagina, like the womb, becomes hypertrophied, and after labor undergoes the same process of involution. Perhaps after the birth of her last child this process was arrested, and the vagina remained thickened and with impaired tenacity. Such a condition would of itself tend to promote a descent of the vagina; for, indeed, in the last months of gestation a prolapse of its anterior wall is by no means an uncommon event. Again, the vascular growths at the meatus urethræ gave so much anguish that she schooled herself into the habit of holding her water as long as possible, and consequently—for the latter act implies the performance of the former—of putting off the evacuation of her bowels. Of course, then, the over-distended bladder and the overloaded rectum, by pouching in the vagina posteriorly and anteriorly, would materially aid in dragging down this already prolapsing canal.

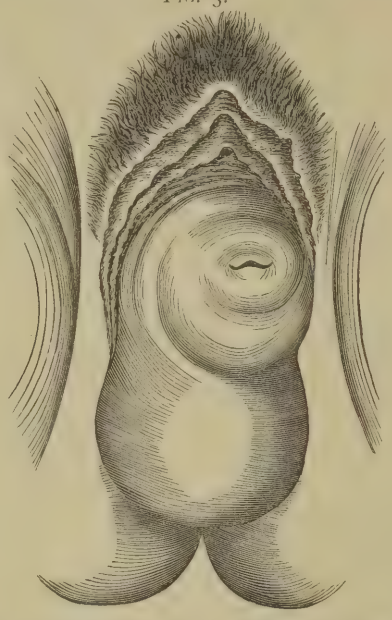
From the first, her bladder has kept pace with the vagina in its descent, until its base is now far below the level of its neck, and the pouch thus formed cannot be wholly emptied. In many cases, from the decomposition of the retained urine, cystitis is excited; even calculi are sometimes formed. Occasionally the neck of the pouch gets tightly jammed under the pubic arch; then the orifices of the ureters may become so obstructed as to bring about a dilata-

tion of the ureters or a hydronephrosis. Fortunately, not one of these accidents has happened to this woman; but, of course, the gravity of the urine contained in this pouch has helped to pull down more of the bladder, and still more of the vagina as well; for these arch-conspirators abet one another. The changes previously detailed have all along been taking place in the intermediate part of her womb, and in the glandular portion of her cervix, until you now see how long and stem-like the former has become, and how much the latter has got to look like the snout of a pig. This resemblance is heightened by an ununited transverse fissure of the cervix, resulting from one of her labors, which exaggerates the eversion of the os.

I told you that the final weight and length of the cervix, aided by the jars of the body, completely invert the vagina, which then pulls the gaping lips of the os widely open. Here are my vouchers: As I push the tumor back into the vagina, the eversion becomes less and less; and now, as I force it out by supra-pubic pressure, the eversion is exactly proportioned to the extent of extrusion. Again, the gravity and prolongation of the cervix, aided by the final descent of the womb as a whole, have smoothed out the rugæ of the posterior vaginal wall into mere water-lines. This could not happen from the weight of the vagina alone; nor, in my experience, does it happen in the simple prolapse of the womb, however complete it may be. Finally, this mechanism of descent explains a remarkable uniformity in the length of the uterus in all those cases of elongation in which the womb itself partly descends and the cervix appears outside of the body. Then usually the sound indicates a length of five inches or thereabout,—a limit attributable to the resistance to any further elongation and descent by the anterior wall of the vagina, which measures about two and a half inches in length. This great length of the uterus, by the way, furnishes a good reason for the pain felt by our patient when she reduces the tumor. For, since the fundus is not very much below its proper position, the return of the tumor—necessarily involving that of the cervix—can be effected only at the expense of either an undue stretching upwards of the suspensory ligaments of the womb, or of a forcible bending or retroflexion of the elongated cervix.

You must not, however, infer that in all cases of this affection the fundus will be found so high up in the pelvis as it is in our patient. On the contrary, in the majority of old cases you will find it very much lower down than it would be in health. Occasionally you will meet with a case—such as some of you last week saw in my private room—in which the elongated and heavy womb has finally overcome the resistance of its ligaments. It will then be found in a state of retroflexion, wholly outside of the body and contained in the vaginal sac. By palpation and the uterine sound, such a complete prolapse is easily recognizable. Even to the eye there are presented certain unmistakable marks. For the tumor is then of large size, and, as you will be able to understand from this figure, which I have borrowed from Dr. Taylor's admirable paper, the bulge of the retroflexed fundus makes the posterior vaginal wall hang down below the snout-shaped

Fig. 3.



apex like a dewlap. Nor, on the other hand, is it rare to see cases in which the fundus has apparently not budged from its normal site.

This affection of the cervix is restricted as a rule to the laboring-classes, and especially to those women, such as cooks and laundresses, whose work compels them to stand much on their feet and to lift heavy weights at a disadvantage. It and a host of other uterine disorders have very lately been attributed to an alleged excitation provoked by the treadle motion of the sewing-machine. I do not believe this; to the pure all things are pure, whilst even in the impure the wearisome movements of a laborious trade could hardly awaken, much less content, any sexual solicitation. True, professional operators on the sewing-machine are liable to uterine disorders, but, as a class, so are all seamstresses. Their susceptibility is not, however, traceable to a prurient source, but to the combined effects of bad air, bad food, over-work, close confinement, the sitting posture, and of such accessories as tend directly or indirectly to determine pelvic or portal congestions. Nor do I believe that onanism, in any form whatever, plays an important part in the production of this disease; for all the examples of it that I have seen have occurred in married women with large families.

(To be continued.)

The Odor of the Breath in Diabetes Mellitus (*Berliner Klin. Wochenschr.*, August 26, 1872).—M. Guéneau de Mussy, in the *Gazette Hebdom.*, July 19, says that for several years he has noticed that patients affected with diabetes have a sour breath that smells somewhat like alcohol, or like the heavy breath of the habitual drunkard. In many cases he was able to diagnose the disease from this odor of the breath, and he also noticed that with the decrease in the amount of sugar in the urine the odor disappeared from the breath.

ORIGINAL COMMUNICATIONS.

PRACTICAL HISTOLOGY IN VIENNA.

A COMMUNICATION TO THE BIOLOGICAL AND MICROSCOPICAL SECTION OF THE ACADEMY OF NATURAL SCIENCES OF PHILADELPHIA.

BY JAMES TYSON, M.D.

(Concluded from No. 57.)

UNSTRIPED muscular fibre was studied in the following manner. A section of fresh intestine of the dog or rabbit was taken, washed by shaking about gently in a very weak solution of bichromate of potash, and then placed in a dark straw-yellow solution of bichromate of potash for three days, during which the solution should be changed at least once. This loosens the connective-tissue net-work, as well as the net-work of muscular tissue, *i.e.* renders the fibres easily isolable. (Any weak acid, as hydrochloric or a .20 solution of nitric, answers the purpose, but the bichromate of potash solution is better.) The muscular coat is then stripped off quite easily, and small portions dissected in the fluid in which the tissue has been macerating. Very beautiful nucleated muscular fibre-cells may thus be obtained, which possess a yellow tinge in consequence of staining by the bichromate of potash.

Of *reagents* a one-half per cent. solution of chloride of gold renders the cells and their bundles more transparent, and the contours of the fibre-cells are more easily followed. There is no effect on the nucleus. Dilute acetic acid renders the nuclei more distinct.

To stain unstriped muscle.—Very beautiful preparations are made by staining, especially with chloride of gold, muscular membrane—as a portion of the stomach of the rabbit—and making sections of the same, which should be made both parallel and transverse to the length of the muscular fibre. In these and all other instances in which preparations to be stained with chloride of gold require washing, this should be done by shaking it about gently in a much weaker solution of the gold, or, what is cheaper, a very weak solution of tartaric acid. The gold staining is then accomplished as described, by mounting the membrane over a fenestra in cork, previous to immersion in the one-half per cent. solution, transferring to acetic acid water, and further hardening in alcohol if the preparation is not sufficiently hard when removed from the acidulated water. The sections are made as before described. It will be easily seen that very different pictures will be obtained in the transverse sections according as they are made through or beyond the nucleus. Beautiful net-works of nerves traversing the muscular lamellæ will also be stained by the chloride of gold. In all cases where sections are not sufficiently transparent, they may be made so by immersing for a few minutes in turpentine, or, better, in oil of cloves, to either of which they must be transferred from alcohol.

Striated muscular fibre was studied in several ways. 1. By maceration for forty-eight hours, more or less, according to the size of the fragments, in a dark reddish-yellow solution of bichromate of potash. It is then dissected with needles and examined. The fasciculi are rendered easily isolable, but are colored somewhat by the bichromate solution, and altogether more altered than by the following methods. 2. Warm small pieces of muscle in a capsule or test-tube containing equal parts of water and one-half per cent. solutions of nitric acid and chlorate of potash, for seven minutes, without boiling. As soon as the fluid begins to vaporize, remove the lamp to a greater distance, but keep up the heat for seven minutes; then transfer to distilled water. The fasciculi become most easily isolable, and may even be shaken apart. The connective tissue is thus dissolved, but less completely than in the next method, and the nuclei of the sarcolemma, as well as of the muscle-substance, are distinctly seen. The latter should be compared with the former. The nuclei in the sarcolemma of muscle are usually smaller than those of the muscular substance, and the latter oftener contain two nucleoli. 3. Boil a fragment of muscle for five minutes in a test-tube, in one part of one-and-a-half per cent. solution of nitric acid, one part of one-and-a-half per cent. solution of chlorate of potash, and ninety-eight parts of water. Place the muscle thus boiled in distilled water twenty-four hours, changing the water once. In this method the connective tissue is completely removed, and even the nuclei of the sarcolemma become invisible.

The distribution of nerves in striated muscle was also studied to a limited extent. This is best studied in animals, in the fresh muscle of those killed by woorara. No special methods were pursued, and many preparations were often examined in the so-called indifferent solution—one-half per cent. chloride of sodium—before nerves could be detected, and no information with regard to their terminations could be obtained. In the fresh muscle of coleoptera, however, as that of the *hydrophilus piceus*, the termination of nerves in the so-called Doyerian plates (*hügel*), and the continuation of the sheath of Schwann (tubular membrane) with the sarcolemma of the muscle, were easily demonstrated. The contraction of muscle is also here beautifully shown.

Alimentary Canal.—Very beautiful sections of the alimentary canal of the dog—œsophagus, stomach, and small intestine—were made by first washing the portion in the very weak chromic acid solution alluded to, hardening in the straw-yellow solution of chromic acid for forty-eight hours, transferring to alcohol for two days, and then making sections in the manner described. These may or may not be afterwards stained with carmine. The yellow coloration by the chromic acid serves also to give the different coats a distinctness not obtained with uncolored preparations. In the case of the small intestine the following layers can be demonstrated with perfect facility. 1. *Epithelium.* 2. *Membrana mucosa.* 3. *Muscularis mucosæ*, or internal muscular coat, composed of two layers,—*a.* circular, *b.* longitudinal. 4. *Submucous connective tissue.* 5. *Muscularis externa*, also composed of two subdivisions,—

a. circular, *b.* longitudinal; and finally, 6. *The peritoneum.*

STAINING OF TISSUES.

Gold Staining.—The general method of gold staining has already been given. Certain modifications must of course be made for special tissues and special objects, as demanded by their size or shape or the points to be demonstrated. Thus, in staining corneæ the period of immersion is longer if it be desired to stain the nerve-fibres than if simply to study the so-called corneal corpuscles, and corneæ of rabbits require, of course, longer immersion than those of frogs. For the former an immersion of as much as three-quarters of an hour was permitted for staining the corpuscles, and one and a quarter hour for nerves. For the latter an immersion of from ten minutes to half an hour was allowed before transferring to the acetic acid solution; the former for corpuscles, and the latter for nerves. In either case the epithelial membrane of Descemet may or may not be removed by pencilling with a camel's-hair brush, or by careful traction with forceps.

In the case of the rabbit's cornea, especially, the stained corneæ may be imbedded and sections made.

Washing is often necessary in order to remove coagula formed by irregular precipitation of the staining substance. This is done by shaking the stained tissue in a test-tube with alcohol, water, turpentine, or other menstruum with which it was last treated.

Again, if it is desired to stain the epithelium and submucous tissue of the intestine of a small animal, as a rabbit, without section of the gut, a portion of the intestine may be filled with the one-half per cent. gold solution, by means of a rubber tube with attached pipette, and allowed to remain thus for ten minutes; then empty and place in the acetic acid solution for twenty-four hours. Further harden, if necessary, in alcohol, imbed, and make sections either of the entire cylinder, or of smaller portions of it, as may be desired.

Beautiful *nerve-preparations* may be made of the tadpole's tail, cutting off a portion, washing in the very weak chloride of gold solution or solution of tartaric acid, staining with the one-half per cent. solution, imbedding, and making sections.

One of the most beautiful manipulations for demonstrating nerves is to fasten a frog on its back, open the abdomen, first inflate the bladder through the common opening of the bladder and rectum, then fill the bladder with the gold solution by means of the rubber tube and attached pipette, allowing it to remain for five minutes, while the exterior of the bladder is kept exposed to a similar solution for the same length of time. Portions may then be cut out and examined in glycerin.

The distribution of nerves in the mucous membrane of the vagina, now claiming considerable attention, is also thus studied. Small portions of mucous membrane are cut out of the vagina of the rabbit, suspended over a fenestra in cork, stained with chloride of gold solution, transferred to acetic acid water for twenty-four hours, and studied in glycerin.

Unfortunately, gold-stained preparations cannot be preserved for any length of time. They are best studied in glycerin, but mounted in this fluid they cannot be relied on for more than a month; though if the cover be cemented by damar lac, they keep even longer. Mounted in oil of cloves, to which they may be transferred from alcohol, and cemented by damar lac, they keep somewhat longer, even a year or more, with little change.

Silver Staining.—It is well known that "silver staining," so called, has this peculiar action, that it affects, not the cell-substance, but a certain intercellular cement, by which the cells seem united, and that it maps out, therefore, districts of cells by staining their periphery. It has its greatest utility in demonstrating the endothelium of blood-vessels, and especially of lymphatics, in serous membranes (centrum tendineum of the diaphragm, pericardium, etc.), but is also used in cornea-staining, in which it marks out the tortuous periphery of the peculiar corneal corpuscles. It is accomplished either by pencilling the organ or tissue of the living animal with a one-half or one-fourth per cent. solution of nitrate of silver, repeating once, keeping in the dark for ten minutes, and then placing in distilled water for twenty-four hours, renewing the water once; or, secondly, by removing the organ either from the living or recently killed animal, immersing in the silver solution in the dark for from one to ten minutes, and transferring to distilled water for twenty-four hours. In all instances the epithelium must be previously removed from the tissue or organ to be stained; which is very easily done by the simple friction of a camel's-hair brush, or by wiping the epithelial surface with a dry cloth. The most successful preparations of this kind I have ever seen were made from the central tendineum of the recently killed rabbit, by Dr. Klein, at the Brown Institution, London. The demonstration of the lymphatics and lymph-spaces was perfect. The preparations are best examined in glycerin, in which they may be preserved for a short time. Nitrate of silver injections of small blood-vessels, as those of the kidney of a rabbit, are also made by means of delicate glass pipettes connected by an India-rubber tube with the syringe carrying the one-half per cent. solution. The manipulation is delicate.

Preserving specimens.—The favorite menstruum at present used in Vienna for mounting all preparations, except the silver and gold stained tissues, is the *damar lac*. To this, preparations are directly transferred from turpentine or oil of cloves, the excess of these being removed by momentary contact with bibulous paper, covered, and allowed to dry; the excess of damar at the edge of the preparation answering at once for cement and wall of the cell. Preparations which have been previously surrounded by watery solutions or glycerin must of course be washed in alcohol before they can be placed in turpentine or oil of cloves; nor can preparations be directly transferred from alcohol to damar lac, but must first pass through turpentine or oil of cloves. For preparations previously immersed in aqueous menstrua, which do not admit of transfer to alcohol, and thence to turpentine or oil of cloves, glycerin is used, and the cover cemented with the damar lac.

Oil of cloves is also much used for mounting, and is the favorite medium for making sections transparent which are not sufficiently so. For this purpose it is more satisfactory than turpentine. An immersion of from a few seconds to several hours is permitted, and sections may remain in the oil of cloves until mounted in damar.

ON THE EFFECTS OF THE BROMIDES IN EPILEPSY, WITH SPECIAL REFERENCE TO THE BROMIDE OF POTASSIUM.

BY M. GONZALES ECHEVERRIA, M.D.,

Late Resident Physician to the New York City Asylum for the Insane, Ward's Island, N.Y.; Consulting Physician to the New York Hospital for Epileptics and Paralytics, etc. etc.

(Concluded from page 136.)

LARGE doses of bromide of potassium do not operate favorably when suddenly administered in the commencement of the treatment; but in all cases it is necessary that epileptics should be brought occasionally under the full physiological effects of the bromide of potassium, and then discontinue it until the effects of the bromide have subsided; then resume the ordinary doses of the salt, and again increase them when the attacks recur, in order to secure a permanent arrest of the disease. Tolerance of the bromide by constantly using larger doses than one drachm in twenty-four hours, when the fits are checked, should be avoided. Nor should the dose be ever augmented and thus prolonged, unless the condition of the patient indicates a threatening attack, or it is required by the severity and frequency of the fits. Epileptics only exceptionally bear more than one drachm of bromide of potassium, daily continued, without soon exhibiting symptoms of bromism.

It is of the utmost importance, when the fits have disappeared for several months, and recovery seems perfect, not to stop suddenly the use of the bromide of potassium, but to decrease its quantity, and to discontinue it in the slowest manner, after a protracted treatment, and seeing every indication that the epileptic habit has been overcome.

I have resorted for several years past to hypodermic injections of strychnia to promote a regular capillary circulation, and remove chilliness and pain from the extremities, or to bring about a rapid healing of atonic ulcers and eruptions in the limbs of inveterate epileptics and paralytics. I have also employed strychnia in such hypodermic injections as a vaso-motor stimulant and tonic, and several cases illustrating their efficacy are published in my work on epilepsy.

Sanson, in 1868, and Brown-Séquard more recently, have called attention to the antagonism of bromide of potassium and strychnia, but they have not alluded to the usefulness of strychnia to remove the above symptoms. Brown-Séquard states that strychnia counteracts the effect of the bromide, preventing the appearance of the bromism. My attention has not been attracted by any antagonistic action between the bromide and strychnia, in any of the cases where I have jointly administered them; but I have never employed, like Brown-Séquard, one-third of a grain of strychnia in conjunction with one hundred and thirty-two grains of bromide in a day,—the largest dose of strychnia I have injected subcutaneously never reaching beyond one-fortieth of a grain.

One of the simplest and safest ways of preventing bromism is by repeated administration of strong coffee. I order coffee always as a medicine and as an important part of the epileptic's diet, for it stimulates the brain, specially opposing itself to rapid disassimilation, and thereby lessening structural changes. In addition, the operation of the bromide is helped by coffee drunk with meals or throughout the day, and in this wise the supervention of bromism is very much delayed, epileptics being thus enabled to take twice as much bromide without the necessity for suspending it, which I deem important to secure the arrest of the disease. I have most closely watched the effects of coffee in epilepsy, and I have every reason to believe that it does not produce any of the evils generally deprecated. On the contrary, epileptics accustomed to it experience a comfortable feeling, and ask for it to rouse themselves from weakness and depression. If administered immoderately from the beginning, it may not be borne with ease, and may, like all stimulants, originate unpleasant effects.

It has been advanced by Duckworth, Williams, and others, that tuberculosis is hastened by the bromide of potassium. I have investigated the relation of pulmonary tuberculosis and epilepsy, and undoubtedly the generation of tubercles in the lungs is favored by the lesion of the medulla oblongata proper to epilepsy. I have traced the pulmonary trouble from its inception, and feel convinced that the association is more than a casual coincidence of the two morbid conditions, the striking frequency of tubercles or other pulmonary lesions I have met with in the post-mortem examinations of epileptics strengthening my belief.

Finally, it is interesting to notice that, while the narcotic effects of morphia injected subcutaneously to assuage pain in labor may operate actively upon the fœtus, conium and bromide of potassium appear free from noxious influence on the fœtus, when given to the mother. One epileptic woman took daily, throughout gestation, one drachm of bromide of potassium in tincture of sumbul, and had not one single fit. Another woman was troubled with three attacks during the last two months of pregnancy, and on each occasion the dose of bromide had to be raised, during a short period, from twenty to thirty grains thrice daily. In another case, during the last four months of pregnancy ninety grains of bromide of potassium were administered daily against nocturnal attacks, attended with *petit mal* in the daytime. The bromide in these last two cases was exhibited with fluid extract of conium and Fowler's solution. In the fourth case the bromide administered in the beginning, in twenty-grain doses three times a day, was, during the last four months of pregnancy, respectively carried up in each of them to forty, fifty, sixty, and seventy-five grains three times a day,

with one and a half fluidrachms of Squibb's extract of conium. In none of the foregoing four cases was the fœtus injured by the bromide. The children borne by the first two women are respectively five and six years old, and that of the last woman, a very lively boy, was sent to the Infants' Hospital about three months after his birth.

I may establish the following conclusions from the foregoing clinical facts:

The bromide of potassium operates actively in a paralyzing manner on the excito-motor power of the sympathetic and spinal nervous system, and produces cerebral congestion. The hypnotic and sedative properties of the bromide of sodium and bromide of calcium appear to be weaker than those of the bromide of lithium, which I have found in its turn a less active sedative than the bromide of potassium. The bromide of ammonium stimulates at first and then congests the brain, bringing about stupor in lower doses than any of the other three bromides here mentioned. The bromide of cadmium exerts no direct action on the nervous system, being a most powerful emetic and purgative, capable of causing, in very small doses, extreme depression.

The bromide of potassium is not a *specific* for epilepsy, but may contribute most efficiently to arrest the fits by suspending reflex excitability of the spinal cord in a more uniform and active manner than any of its kindred salts.

The benefits of the bromide of potassium increase and are better secured by administering it combined with conium, ergot, arsenic, and strychnia.

Sixty grains is the average daily amount of bromide of potassium required in ordinary cases of epilepsy; but it is necessary to keep epileptics, at different intervals during the progress of their attacks, under the full physiological effects of the bromide, to suspend it until the bromism is dispelled, and then to resume the salt again in ordinary doses.

The bromide of potassium alone exerts little or no effect on the attacks of *petit mal*, unless associated with large doses of ergotine (gr. vj to gr. xvj) and conium. In epileptic insanity, or in any other form of insanity, the hypnotic and sedative properties of the bromide of potassium are usually unavailable when the salt is administered alone, a refreshing sleep and subsequent quietness being more readily obtained when the bromide is prescribed along with some narcotic, such as conium, cannabis indica, hyoscyamus, and still better with full doses of ergotine.

The bromide of potassium should never be discontinued suddenly, even when the epileptic fits have not recurred in a long time, but the dose of the salt should be gradually decreased, and the treatment left off insensibly, when there is every indication of the complete eradication of the epileptic habit.

Nothing proves that the efficacy of the bromide of potassium in epilepsy bears any relation to the existence or severity of the bromide eruption. Arsenic prevents or mitigates it, and acts further as a valuable tonic. Subcutaneous injections of strychnia are the most efficient remedy to re-establish the depressed peripheral circulatory activity, and to operate also as a stimulant in epilepsy.

Coffee is one of the best means of correcting the unpleasant action of full doses of the bromide; it favors its effects, is in addition an invaluable cerebral stimulant, and should always constitute an important part of the epileptic's diet.

Bromide of potassium, when taken by the mother in large and prolonged doses, does not seem to have any noxious influence on the fœtus.

PERSONAL REMINISCENCES OF STATISTICAL RESEARCH.

BY ROBERT P. HARRIS, M.D.

IT may be of interest to the readers of the *Medical Times*, as it has been to a few intimate friends, to hear some of my experiences in the work of recalling from the past the lost or forgotten records of the Cæsarean operations of the United States,—a labor which, although not satisfactorily completed as yet, has very nearly approached this desired end. My first work was the dull, tedious, and unsatisfactory one of consulting the various medical journals, effete and extant, of our country, and some of the English and French journals which are known to have had occasional contributions from this side of the Atlantic, prior to the publication of our own medical periodicals; and to separate for rejection all cases reported as *Cæsarean* which were not the subjects of true *gastro-hysterotomy*.

At the very commencement I came upon the first American case, reported by Fleetwood Churchill, and credited to "*Mr. Cellen, New York.*" I opened a correspondence with parties in that city, examined the journals in our libraries, and finally, from a correspondence of dates, etc., became satisfied that there was no Mr. Cellen; that the case credited to him was operated upon by the woman herself; and that the ground for this name was the fact that the case was reported by Dr. Bassett, of Nassau, before the Rensselaer County Medical Society, *Dr. McClellan* being the presiding officer on the occasion.

This experience decided me to regard the work of no predecessor, but to commence *de novo*, and thoroughly examine every report, and as far as possible every State, and into the foundation of the various current rumors, some of which have been thoroughly credited for years past. One of the first of these reports that came to me was from Cincinnati; a gentleman having assured me of its truth, and stated that he passed the residence of the lady at the time of her illness and learned the fact of the operation from a neighbor. A thorough research has satisfied me that Cincinnati has yet to have her first Cæsarean case, notwithstanding that a gentleman long resident in this city was pointed out to me years ago as having been delivered from his mother by this operation.

Lancaster, Pennsylvania, was the seat of another rumor, as reported by Dr. Joseph G. Nancrede, in 1835, in his account of Dr. Gibson's first operation upon Mrs. Reybold, of Philadelphia. A careful in-

vestigation leads me to believe that neither in Lancaster nor in the county has a case occurred.

But the best apparently authenticated case came from Bradford County, where a certain well-known judge, of French parentage, who died a few years ago, at an advanced age, was always believed to have been taken from the abdomen of his mother by a French surgeon, the lady surviving the operation a number of years. The story came to me from a neighbor of the judge, and I was in great hopes it would prove correct, as it would have given to Pennsylvania the oldest operation of the Union; but I was doomed to be disappointed, for I succeeded in finding the physician of the judge, a lady who was present at his birth, and a second doctor, who had examined the abdomen of the mother, and, expressing surprise at not finding the cicatrix, was told that there had never been the least foundation for the current story. The family physician of the judge had heard the report for more than thirty years, and allowed it to pass without question, until after he received my letter of inquiry. So generally was this old rumor credited, that I received, just after I had ascertained the truth, a letter from the town where the judge resided, in which a physician assured me in strong terms that Madame L. had been operated upon as the report stated. As I had ascertained the truth, I thought it due to the doctor to convince him of his error, and through him set on foot a counter-statement. The French doctor was fond of a little excitement, and probably said something at the time of the birth, out of which grew the report in question, and, as he returned to France soon afterwards, it failed of a contradiction on his part, which it might otherwise have received.

It is often less difficult to find out the truth of a rumor than to discover a lost case, as I know to my regret in several instances where the operations were successful and the names of the surgeons given. The late Dr. Elias Samuel Cooper, who died in San Francisco in 1862, went to that city in 1855, from Peoria, Illinois, where he had operated upon a German woman, who was said to be still living in 1862. Dr. Cooper never reported anything in regard to this operation but the fact, and that the woman was residing in Illinois; his second operation was in San Francisco, and was also successful. Here the matter still rests; for, with all my letters to California, Ohio, Indiana, and Illinois, I have never been able to find any one who had ever heard where the operation had taken place; but I do not entirely despair yet, as my next letter from California may perhaps throw some light upon the subject.

It is probable that the Cæsarean operation was first performed by French surgeons in Louisiana, and possibly before the year 1803, when it became a State. That it did precede the other States is generally believed, and with reason; but the whole of the cases thus far belong to the dead past, except one, where Dr. Prevost, of Donaldsonville, is reported to have performed the operation several times with success, upon a mulatto, who died under the last infliction. This report has given me a great deal of trouble, and is still, at the end of two years, where I first found it, with no better prospect of entire exhumation than there was then. My work has satisfied me that unfavorable cases are more readily attainable than those which have terminated favorably. This is particularly unfortunate just now, as the excessive mortality of the last four years has given a preponderance of death in my whole table, when the favorable cases sought for would more than counterbalance them, making the successful operations 37 and the fatal 34, instead of 31 and 33, as they stand now. It is somewhat singular that in Great Britain, where there have been 107 cases and only 18 recoveries, there should have been 2 recoveries out of 9 operations in four years, against but 1 recovery out of 9 in the same period in the United States, where out of the first 25 reported cases there were 15 recoveries. The two successful foreign operations were both performed in Scotland, and promptly resorted to. Our own cases were *mostly* either very late in performance or in very unfavorable subjects, and decidedly below the average in this respect.

One of my chief sources of disappointment in obtaining information by correspondence arose from the fact that the term *Cæsarean* appeared to convey no very definite meaning to the minds of those addressed, and I was constantly annoyed by finding, after a thorough search for a reported case, that it was one of gastrotomy following rupture of the uterus, the opening of an adherent and perhaps inflamed extra-uterine cyst, or something equally foreign to the question, and of a decidedly different measure of gravity. Even professors in medical schools, judging from their reports, did not appear to be aware of the fact, that to constitute a Cæsarean operation we must not only incise the abdominal walls, but cut into the cavity of the uterus through the abdominal wound. Thus, out of eight cases reported by two physicians, I was, after a considerable waste of time and trouble, obliged to reject all but one. One of those rejected was the operation of a surgeon long since dead, which his son, also in the profession, assured me had been one of gastro-hysterotomy. Not feeling perfectly satisfied with the particulars obtained, I pushed my researches until I finally met with, in print, a letter from the operator to the late Prof. Meigs, proving the case to have been gastrotomy after uterine rupture.

This form of gastrotomy is certainly less fatal than gastro-hysterotomy, and cannot with any propriety be regarded as Cæsarean, or permitted to enter into the statistics of the latter operation. It is, if anything, a more important surgical procedure, as it tends to save the life of a class of subjects not bodily deformed, or apparently diseased, and ought to be much more frequently resorted to than it is. Drs. John Neill and William Byrd Page, of this city, have each performed it with success, upon cases which were certainly far from promising at the time of the operation.

We hear also of the *vaginal Cæsarean operation*, meaning either *hysterotomy*, for the relief of uterine occlusion or otherwise uncontrollable rigidity, or the *vagino-cystic section*, as performed with safety to

the mother and an extra-uterine fœtus, in 1816, by Dr. John King, of Edisto Island, South Carolina. *Gastro-elytrotomy*, fortunately, has a special title, and therefore cannot be confounded with those mentioned.

If statistics are to be of any value in establishing a *prospective recovery scale* after capital operations, then they must be rigidly kept to one special line of cases, and no trouble must appear too great in the eyes of the worker, that may be necessary to weed from his rough notes every case not thoroughly established upon reliable testimony. When I entered upon the self-imposed task related in this paper, I felt satisfied that the general opinion in this country with regard to the high mortality of the operation in question was too much influenced by the want of success in the British Isles; an idea which, by making the "section" a matter of dire necessity instead of election, had a tendency to vastly increase the mortality, by postponing the resort to the knife until too late to save life, except in a small proportion of cases; and I think I have established the fact that promptness of operation in the United States will save a large proportion of both women and children. But for the fact that this operation is frequently performed upon those who are extremely dwarfed and crippled, I see no reason why it might not be made to approach the measure of success known to have resulted from gastrotomy after rupture of the uterus,—*i.e.* 75 per cent. saved, as proved by the valuable researches of Dr. Trask, of Brooklyn.

This operation has been of more frequent performance in the United States than gastro-hysterotomy, and is one which is oftener required to be done, in fact very much oftener, than it is resorted to. If it were generally performed after rupture, there would be a much less mortality as a consequent of the accident than there is now.

SKIN-GRAFTING AS A TREATMENT OF INDOLENT ULCERS.

BY W. H. PARISH, M.D.,
One of the Resident Physicians to the Philadelphia Hospital.

Read before the Philadelphia Hospital Medical Society, June 1, 1872.

INDOLENT ulcers, especially when occurring on the anterior surface of the leg, are so frequently exceedingly indomitable under our most approved methods of treatment, that we willingly, though not very confidently, give trial to any new remedial measures that may be brought to our notice.

The transplanting of minute portions of healthy integument on to the granulating surface has been now tested by numerous surgeons, and the fact that these grafts will, under favorable circumstances, unite with the tissue of the ulcer and form so many *foci* of cicatrization, has been well established.

The degree of success, however, as compared with that obtained by other modes of treatment, seems as yet but indefinitely ascertained; and the kind of ulcer to which this treatment is or is not applicable is not clearly set forth. These points can be elucidated only by extended experience and close observation.

I have adopted the grafting process in ten cases, and in each case one or more of the grafts retained vitality and became encircled with cicatrization, evidently aiding materially in the healing of the ulcer.

These ulcers were all on the anterior portion of the leg, and were all, with the exception of one, of several years' duration. Not one of them was dependent on a syphilitic taint, and I was careful, by appropriate preparatory treatment, to secure as healthy a condition of each as seemed practicable. If there was too much inflammation, as indicated by a reddened, angry appearance of the ulcer and the integument around, the degree of inflammation was reduced by rest and the usual antiphlogistic means. If there was a tendency to the formation of a slough, this tendency was first removed. If there was an appearance of extreme sluggishness, stimulant applications were made for a few days.

I would especially call attention to the importance of freeing the granulating surface of any diphtheritic membrane that may be present. My first case, a man, presented this condition over the entire area of the ulcer, it being about the size of the palm of the hand, and of six years' duration. At first the exudation was not observed. On the twelfth day the grafts, failing to take root in the granulations, had entirely disappeared. Now removing the false membrane, which came away in strips, some about four lines in width, and applying new grafts, a favorable result was obtained. In a few days the ulcer was dotted with several islands of cicatricial tissue; and the healing was entirely effected in a few weeks.

In one other case this pseudo-membrane existed. In both it bore a resemblance to the false membrane of croup. The granulations could be seen, but with their florid hue changed by this drab-colored semi-opaque covering.

After having prepared the ulcer, I, with forceps and scissors, clipped, usually from the inner side of the arm, a portion of the integument measuring about three by four lines, and sufficiently thick to comprise the true derm. This section I cut with scissors into eight or ten pieces. Each piece was placed on the granulating surface, the epidermis being uppermost. These pieces were then pressed against the ulcer and held *in situ* by strips of adhesive plaster. The entire ulcer was covered with similar strips, and the limb surrounded with a bandage.

This dressing was permitted to remain for two or three days, when the plaster was found in position, but no longer adherent to the granulations, being loosened by the discharges. The grafts at that time could be detected as pale, transparent specks among the florid granulations. The same dressing was continued, usually until the ulcer was healed, being reapplied every two or three days.

During the early portion of this treatment the patient was confined to his bed, and when permitted to sit up was required to keep the leg elevated, and was strictly enjoined not to walk much, nor to stand long at a time until after the cure was obtained.

On the sixth or ninth day the transplanted integument will present a pinkish appearance, and close observation will find evidences of union and vitality. Do not, however, pronounce the attempt a failure too hastily if these appearances cannot at that time be discovered, for a point of cicatrization may be hidden among the granulations, to come to light in a few days. In one case, on the twelfth day after I did the first transplanting, I did a second, having lost sight entirely of the grafts. But on the fifteenth day, again looking at the ulcer, I found two of the first grafts distinct, and cicatrization established about them. Some of the second took hold, and the process went on to a cure.

The length of time occupied in the cure of an ulcer, under whatever treatment, seems to be so much influenced by the individual character of each ulcer, and every attempt at a description of its characteristics always so decidedly unsatisfactory, that no one without a personal experience extensive and varied can form an opinion as to the comparative value of this curative process.

However, after a rather protracted service as interne in the surgical wards of this hospital, which is a favorite resort of leg-ulcers, and with ample opportunities to observe and adopt various kinds of treatment, I am inclined to look with decided favor on this plastic operation, and to think that in many cases a cure may in this manner be greatly hastened.

MORBID ANATOMY OF THE EPIZOÖTIC.

(Communicated by FRANK WOODBURY.)

PROF. GROSS, at the Jefferson College clinic, recently exhibited the post-mortem specimens obtained from a horse which died during the late epidemic, upon which he made the following remarks: "The horse was of medium size, and fourteen years old; he had been previously healthy during seven years in the service of Dr. Maxwell, his last owner. During the prevalence of the horse disease he suffered in common with his solipede brethren, and, although treated with the greatest care, he relapsed, when apparently convalescent, and died. This may be taken as a typical case of death from the disease, complications having been avoided by the treatment.

"The examination, carefully made by Mr. West, disclosed a large quantity of serous fluid in the thoracic cavity; the lungs were partially adherent, and a section sank in water, showing a condition of infiltration or hepatization. In the trachea and larger bronchial tubes spots of lymph and numerous ecchymoses indicated the severity of the inflammation, and the mucous membrane, as far as the anterior nares, was discolored and covered with a muco-purulent secretion. Many of the bronchial lymphatic glands were enlarged. There was no evidence of disease discovered in the œsophagus or remaining viscera, and death evidently resulted from pleuro-pneumonia. The sweeping character of this disease and its rapid spread over the continent lead me to consider it of the nature of dengue. It is not communicable by ordinary contact; the morbific germs float in the atmosphere, making it epidemic rather than contagious."

THE INFLUENCE OF ALCOHOL UPON THE TEMPERATURE OF THE HEALTHY HUMAN BODY (Professor Binz, of Bonn: *Virchow's Archiv*, vol. liii., part 4, 1871).—The old opinion that alcohol in the form of spirituous liquors increased the temperature of the body has been altered in later days by experiments. From experiments performed on the lower mammals it appears that the temperature is decreased by the introduction of alcohol into the system, though by no means to a dangerous degree. Respecting the human mammal the question has remained undecided, until recently one of Prof. Binz's pupils, Dr. Mainzer, has performed a series of experiments, mostly upon himself, for the purpose of determining the facts concerning the action of alcohol upon the temperature of the human body. The empirical statements of Todd had already rendered it probable that alcohol does not increase the temperature of the fluids of the body. Dr. Binz gives the results of his pupil's labors as follows, and says that nothing has been neglected to make the experiments perfect. Thirty observations, three to four hours long, were made, after which twenty-four were made upon Dr. Mainzer, and six upon one of his companions.

Both are healthy men, and accustomed to the use of alcohol in the daily enjoyment of the German national drink.

The observations were made upon Dr. Mainzer and his friend while undressed, lying in bed, with light covering thrown over them. The temperature was taken by means of a thermometer inserted into the rectum. This remained in the rectum twelve minutes,—being inserted every fifteen minutes.

The time for making the observations was from 7 to 10 in the forenoon, from 3 to 7 in the afternoon, and from 9 to 12 in the evening.

The alcohol was 98 per cent., and the quantities taken were 15, 40, 50, 75, and 80 cubic centimetres. It was usually mixed with twice or three times its bulk of water.

Mainzer concludes his labors with these words: "No important change in the temperature of my body can be discovered after drinking 98 per cent. of alcohol in doses of 15 to 80 cubic centimetres." Mainzer's friend appears to have been somewhat more sensitive to the effects of alcohol, and his temperature fell relatively lower, although *no toxic influence* of alcohol was observed. These results agree with those already obtained by Ringer and Rickards from experiments upon the human body.

Neumann obtained similar results from experiments upon rabbits; in which the administration of alcohol produced the characteristic effects more slowly in those already accustomed to its use by previous experiments.

Bouvier has drawn the conclusion that alcohol can reduce the temperature of the body in fevers only when given in continued and *not small* doses.

It is yet an open question when this administration of alcohol should occur. That under certain circumstances it may prove beneficial, Manassëin and Bouvier have shown upon septicæmic animals. Mainzer thinks that his experiments prove that alcohol cannot produce objective heat in the human economy, but that, on the contrary, it brings about a decided diminution of the temperature. [See also an article on this subject in the *Times* for October 5, 1872, p. 13.]

PHILADELPHIA
MEDICAL TIMES.
A WEEKLY JOURNAL OF
MEDICAL AND SURGICAL SCIENCE.

The Philadelphia Medical Times is an independent journal, devoted to no ends or interests whatever but those common to all who cultivate the science of medicine. Its columns are open to all those who wish to express their views on any subject coming within its legitimate sphere.

We invite contributions, reports of cases, notes and queries, medical news, and whatever may tend to increase the value of our pages.

All communications must bear the name of the sender (whether the name is to be published or not), and should be addressed to Editor Philadelphia Medical Times, care of the Publishers.

PUBLISHED EVERY SATURDAY BY
J. B. LIPPINCOTT & CO.,
715 and 717 Market St., Philadelphia, and 25 Bond St., New York.

SATURDAY, DECEMBER 14, 1872.

EDITORIAL.

THE ANNUAL REPORT OF THE SURGEON-GENERAL U.S.A.

THIS concise and business-like document, now before us, contains some facts of general interest, and some which will specially engage the attention of members of our own profession. We will mention them in this order.

The United States army consisted, during the fiscal year ending June 30, 1872, of an average strength of 24,101 white and 2494 colored troops,—making 26,595 in all. During the year, this force required the disbursement, for medical and hospital purposes, of $177,753.66.

Among the white troops the cases on the sick-list amounted to a proportion of 1974 per 1000, or nearly two entries for each man during the year; of this, 1671 per 1000 were cases of disease, and 303 per 1000 were wounds, accidents, or injuries. Among the colored troops the proportion on the sick-list amounted to but 1409 per 1000, viz., 1178 cases of disease, and 231 of wounds or accidents.

Among the white troops the proportion of deaths was 15 per 1000,—11 per 1000 of disease, and 4 per 1000 of wounds or injuries,—1 in 130 of the cases treated. Among the colored the deaths were 22 per 1000, viz., 18 per 1000 of disease, and 4 per 1000 of wounds,—1 in 65 of the cases treated.

The discharges on "Surgeon's Certificate of Disability" were, among the white troops, 846, or 35 in 1000 of mean strength; among the colored, 76, or 30 in 1000 of mean strength.

Now, when we look at these figures, the first impression would be that the colored troops were the hardier, since they had 565 per 1000 fewer on the sick-list in the year. On reading further, however, we find that the proportion of deaths from disease was twice as great among the colored as among the white troops, while that from all causes was 1 in 65, to 1 in 130 among the white. The explanation of these differences would perhaps appear if a statement were made of the service on which the sets of troops were respectively engaged, the facilities of obtaining supplies, the forms of disease prevalent, and some other modifying circumstances which may not now suggest themselves.

Some of our readers will doubtless be surprised to learn that during the last year (seven years having elapsed since the close of the war) 28,481 applications for information, "chiefly in regard to the cause of death or discharge from service, and the hospital history of soldiers dead or disabled during the war of the rebellion," have demanded attention at the record and pension office.

The Army Medical Museum has been enriched by the addition of 1022 specimens. The library contains 19,000 volumes and 7000 pamphlets.

A curious fact appears in the following statement:

"The number of applications approved during the year for artificial limbs or commutation for the same was as follows:

COMMUTATION.		LIMBS IN KIND.	
Legs	148	Legs	75
Feet	7	Feet	4
Arms	219	Arms	27
Apparatus	132	Apparatus	1"

We trust that such action will be taken by Congress as will provide for the early distribution of the first portion of the Medical and Surgical History of the War. This great work, which has been carefully prepared under the supervision of the intelligent attachés of the Surgeon-General's office, will form a most important addition to our professional literature. We cannot but feel a pride in the volumes already issued from the same source, which, for accuracy, scientific value, and elegance of execution, have been at least equal to those of older countries.

In concluding this notice, which we trust will not seem longer than the importance of its subject warrants, we must allude with some surprise to the large number of vacancies in the service,—fifty-nine, four of which are surgeoncies, and *fifty-two* assistant-surgeoncies. The report justly urges the necessity of filling up the medical corps to the

number provided for by Congress in 1866; a recommendation which it is to be hoped will have due weight.

THE FEE-BILL.

PHILADELPHIA stands alone among cities in the possession of a rigid fee-bill, carrying a certain weight of authority as having been adopted by the College of Physicians, and employed as a guide by many practitioners in making out their accounts. We have so recently alluded to the matter of compensation for medical services, that we need hardly go over the general ground again, but would urge once more the absurdity of assuming that the value of every man's professional attendance is the same, and to be charged for at the same rate. Skill, experience, reputation,—all these should be worth something pecuniarily, and the public would recognize the fact if the profession did. It is recognized by the army and navy authorities of every civilized country, in the increase of rank and pay accorded to medical officers in proportion to their length of service. Again, to reckon by visits only, without regard to the varying trouble and responsibility involved in different cases, or to the ability of the patients or their friends to pay, is manifestly absurd.

In point of fact, the fee-bill, if binding at all, is so only upon the Fellows of the College of Physicians. It is practically disregarded by many of them, and indeed must be, unless those who attain success in business are willing to be overworked and underpaid. Lawyers have no such tariff; they charge what they can get,—that is, what the public consent to pay them for their services.

Let us suppose the fee-bill done away with entirely: who would be the worse off? Surely not the physician, for he knows well what his professional brethren consider the average value of their services, or he can readily find out; and he can tell what his investments in labor, time, money, and the acquisition of skill and experience have been. As surely not the public; for they must, by an inexorable law of compensation, if they want underpaid doctors, have inefficient ones. We think the results of observation in other departments of skilled labor will show that, in the long run, good work must be well paid for, or the energy and ability it demands will flow into other channels.

It is earnestly to be hoped that this futile fee-bill may be abolished altogether at no distant day.

DR. ANGUS MCLEOD, an East Cambridge physician, was arrested, December 6, for concealing a case of smallpox.

PROCEEDINGS OF SOCIETIES.

PATHOLOGICAL SOCIETY OF PHILADELPHIA.

THURSDAY EVENING, OCTOBER 24, 1872.

(Continued from page 156.)

DR. JAMES TYSON exhibited the following specimens:—

1. *Aortic and mitral disease; perforation of one leaflet of the mitral valve.*

T. McF., shoemaker, intemperate, aged 40, single, born in Ireland, was admitted to the Philadelphia Hospital January, 1872. Parents quite healthy. Has already been in the house nine different times, exclusive of the present admission, for the same ailment. He has suffered much from inflammatory rheumatism, and at certain periods of his life had typhus and intermittent fevers. In 1860, after two severe attacks of rheumatism, he noticed a failure of strength and shortness of breath, and an inability to lean forward, run, or lift anything, without getting unpleasantly out of breath. Two years afterwards he applied for treatment at the Northern Dispensary in this city, where he was told, for the first time, that his heart was diseased. Since then the symptoms have increased in intensity. He has occasionally had swelling of the feet, knees, and hands, but no two members were ever swollen at the same time. Cough sometimes troubles him; he sleeps very well.

May 21.—On physical exploration, inspection reveals a concavity produced by depression of the lower two-thirds of the sternum and the attached costal cartilages. There is at present no undue movement of the chest. The seat of the impulse is less than an inch to the right of the nipple, where there is no marked upheaving produced. The superior border of the heart's dulness is in the fourth interspace. The right lateral border is between the middle of the sternum and its left edge, whence it extends half an inch to the left of the nipple. Inferiorly the tympany of the stomach is noted in the sixth interspace.

Auscultation reveals a double rasping murmur heard over the entire organ, but more loudly at the base.

He remained in the house during the entire summer, scarcely at all relieved by any treatment which could be suggested. For two weeks previous to his death he was the subject of an obstinate dysentery, and one week before he died there supervened an acute purpuric condition of the extremities, which made its appearance in a single night.

Post-mortem examination.—The body was œdematous throughout. There were numerous purpuric spots on the extremities, most abundant upon the hands and feet.

On section, the *pericardium* contained something more than the normal quantity of fluid. The *heart* itself was enormously hypertrophied, weighing 27 oz. when emptied of clots, and presented two opaque white patches on its exterior, one about an inch in diameter over the right ventricular surface, and a second half an inch by an inch and a half over the left ventricle, near its apex. The aortic valves were enormously thickened, the deposits on the edges of two of them having undergone calcareous change; one of the cusps was perforated at its base by an opening half an inch in diameter, the edges of which were formed by a ring of cauliflower-like deposit of calcareous matter. The mitral valves were also greatly thickened, and contained deposits on both surfaces, those on the auricular face of the valve having undergone calcareous change. The tricuspid valve was also thickened, but the pulmonary cusps were normal.

The *liver* was enlarged, weighing 4 lbs. 3½ oz.,

and was also fatty. The *spleen* was normal in size, but was somewhat nodulated in its upper extremity and presented, in this situation, an infarctus the size of a horse-chestnut, most probably the result of capillary obstruction caused by an embolus from the valves of the heart.

2. *Chronically contracted kidney.*

P. D., aged 52, a native of Ireland, and intemperate; considered himself a well man until January, 1871, for a number of years before which date he was engaged in driving a hack night and day, being often subjected to the severest exposure. At this time he was taken with a shortness of breath and a cough, notwithstanding which he continued to pursue his occupation until July of this year, when he entered the house for the first time. In April he first noticed a swelling in his feet, which gradually became worse, until his thighs and genitals became involved. He remained in the house four weeks, during which time there was apparently no improvement. Returning to his home, he continued to grow worse, and re-entered the wards early in September, when he presented œdema of the extremities, genitals, and abdomen; he had also a cough and much shortness of breath.

Examination of the urine, September 17, 1872, gave the following result:

Quantity in past twenty-four hours 30 oz.; reaction acid; sp. gr., 1020; quantity of albumen very slight. The microscope revealed granular and hyaline casts, some of which contained fragments of epithelial cells. He was ordered solution of acetate of ammonia and tr. chl. iron thrice daily, with nourishing diet and stimulants. The amount of urine passed continuing the same, cloths steeped in inf. digitalis were applied to the abdomen; for a few days the urine was augmented in daily amount, but soon fell to 25 oz. in the twenty-four hours.

October 4, 1872.—His face is swollen, and he is enormously œdematous in legs, thighs, genitals, arms, hands, and thoracic and abdominal walls. There is also ascites, and effusion into left pleuritic cavity. The lungs are also suffused with moist râles, and his dyspnœa aggravated, especially during paroxysms of coughing, when his face becomes livid. He was ordered a stimulating expectorant mixture.

October 8, 1872.—Condition not materially changed, except that he has less difficulty in breathing; respiration is, however, still labored. For the last few days he has had diarrhœa, during which the œdema has slightly decreased.

He died suddenly on the morning of October 10.

The *post-mortem examination* was made three hours after death. There was general œdematous infiltration of the connective tissues, ascites, and left hydrothorax; firm adhesion of the entire right lung to the corresponding chest-walls. The lungs were, however, normal.

The *heart* was enlarged, weighing 18 oz., its cavities dilated, and walls firmer and thicker than in health. The edges of the mitral valve were thickened, and a few small atheromatous patches were on its auricular surface. The aortic valves were unchanged, but the aorta itself was the seat of atheromatous deposit. The valves of the right cardiac cavities were unaltered.

The *liver* was small, weighing 2 lbs. 3 oz., "nutmeg" in appearance, yet very firm. The spleen was very small and contracted, weighing but 2½ oz., its trabecular tissue unusually distinct.

The *kidneys* weighed conjointly 9½ oz., and exhibited the same peculiar firmness noted in the case of the other tissues, but even more marked. The capsule was adherent, and when stripped off exposed a granular surface. On section, the appearance could scarcely be said to be other than normal, though upon fracture of the organ the granular appearance was again evident.

Remarks.—It is not unimportant to observe that the extensive dropsy so uncommon in connection with this form of Bright's disease (the contracted kidney) is accounted for in this instance, at least partially, by the cirrhotic liver also present.

3. *Cancer of cardiac and pyloric orifices of the stomach,* from H. W., aged 70, a Pennsylvanian. He has been apparently healthy, except as to occasional attacks of rheumatism, until about the middle of June, 1872, when he began to complain of a dull burning pain in the epigastrium, which continued and became worse after eating, when a sense of distention and weight was superadded. Later, he vomited his food, and complained of nausea at other times, especially in the morning before eating. Occasionally, also, he vomited small quantities of blood. His bowels were obstinately constipated, being often without a dejection for five or six days.

There was exquisite tenderness on pressure in the epigastrium, and percussion-dulness in the median line two and a half inches below the end of the ensiform cartilage, and thence towards the left to the edges of the ribs, and towards the right as far also as the edges of the ribs, but an inch lower down. There was, however, no sense of a tumor communicated on palpation.

About the 10th of September it became quite impossible for him to retain any solid food, when he was restricted to a diet of milk, of which he took a pint daily in divided portions. Thus administered, the milk was retained, and the plan was so successful that the quantity was soon increased to a quart daily. About the 6th, however, he was no longer able to retain the milk in any quantity, while he seemed to reject it, not by an act of vomiting, but by a species of regurgitation. Thenceforward emaciation progressed, and he died on October 18, 1872.

The *post-mortem examination* was made six and a half hours after death. On opening the abdomen, no visible derangement was present until the omentum was removed, when a white, glistening prominence was noted, which proved to be the pyloric end of the stomach, thickened to the extent of three-fourths of an inch in section, and for two and a half inches towards the centre of the stomach. The cardiac end was similarly involved, and to a like degree, while the body of the stomach was normal. To the naked eye the appearances were rather those of a hypertrophy of the muscular substance of the organ in these situations.

Remarks.—The regurgitation of food here noticed is probably explicable by the condition of the cardiac orifice of the organ. The temporary benefit derived from the milk-treatment is quite in accordance with recent experience in similar cases.

4. *Pneumonic phthisis of right lung; miliary tuberculosis of the left lung as a sequel.*

Susan B., unmarried, but having given birth to one child, was admitted to the Philadelphia Hospital August 8, 1872. She was previously quite healthy. In July, while very warm and menstruating, she took a cold bath. This was followed by suppression of her menses, and a "cold," from which she never recovered. She however, continued at service until a few days before admission.

When Dr. Tyson assumed charge of the wards, on September 12, 1872, she had constant high fever, hurried respiration, a hot skin, and a temperature of 103° to 104°; also an annoying cough, with tenacious dark-gray puruloid expectoration.

Physical exploration showed resonance impaired on the right side anteriorly, and in the axilla; blowing respiration over the whole of this region, with moist râles and cooing sounds in the lower part of the chest. On the left side anteriorly, and in the axilla, there seemed no deficiency in resonance, though respiration appeared harsh in these situations. The pos-

terior part of the chest was not examined, because of the great inconvenience it gave the patient.

These symptoms continued unabated until she died.

The *post-mortem examination* revealed marked thickening of the pleural covering of the *right lung*, while the organ itself was riddled from apex to base with small cavities, varying in size from that of a pea to that of an English walnut, and chiefly oval in shape.

The *left lung* was the seat of diffuse miliary tuberculosis.

REVIEWS AND BOOK NOTICES.

THE MICROSCOPE AND MICROSCOPICAL TECHNOLOGY. A Text-Book for Physicians and Students. Translated from the German by GEORGE R. CUTTER, M.D., Clinical Assistant to the New York Eye and Ear Infirmary. Wm. Wood & Co., New York, 1872. 8vo, pp. 658.

Those who are familiar with Frey's admirable manual will feel gratified to Dr. Cutter for this very readable translation, which enables our American and English students who are unacquainted with the German tongue to participate in the instructions of the renowned Zurich professor. Any attempt to criticise a text-book whose merits are so pronounced that (as we learn from the translator's preface) it has already, in the few years since its first appearance, passed through four large editions abroad, would of course be useless; and we shall therefore confine ourselves to pointing out some of the numerous excellencies and few deficiencies in the scope and character of the work.

Professor Frey commences with a clear and concise account of the theory of the microscope, its varieties, accessory apparatus, and use, which extends over about one hundred pages; after which, full and elaborate directions for preparing, staining, injecting, and mounting microscopic objects occupy a nearly equal space. The remaining portion of the volume treats of the different normal and pathological tissues, secretions, etc. of the human body, with occasional illustrations from the domain of comparative histology, when required for complete elucidation of the subject. These directions for investigation possess an especial value to the American observer, on account of the explicit manner in which are described the manifold improved methods of demonstrating the various structures in their healthy or diseased conditions, which have rendered the German pathological laboratories so famous throughout the scientific world.

The imperfections of the volume are, in the first place, that its instructions, like those of most similar manuals, are often couched in technical language, and preceded by such scanty explanation of minute difficulties (which so fatally obstruct the path of a beginner) that only advanced students can reap their full benefit. Secondly, the number of diameters which each specimen is represented as being magnified is generally left undesignated, and this neglect occurs even in Fig. 171, copied from Prof. L. Beale, who has so justly and ably advocated the importance of always specifying the amplification under which each microscopic figure is drawn. Thirdly, whilst most of the references are to German instruments, etc., and, therefore, sometimes almost useless to Americans, their value is still further impaired by the fact that no uniform standard for prices, measurements, and so forth, is adopted; the cost of various articles being given as occasion serves, in thalers, francs, pounds, or dollars, and dimensions stated in millimetres, parts of a Paris line, or subdivisions of an English inch, without any attempt at reduction. Lastly, among the minor deficiencies we note the omission of Dr. Fenwick's invaluable method for detecting lung-tissue in sputa, of which both author and editor appear to be entirely ignorant, notwithstanding it adds so much to the certainty of our diagnosis in phthisis; the absence of any drawings explanatory of the dermatophytic affections; and the less than scant justice done to our leading microscope-dealers in Philadelphia. The work is declared upon the title-page to be profusely "illustrated with 343 engravings on wood," although this seeming wealth of embellishment is to a certain extent fictitiously augmented by the somewhat ingenious and altogether economical device of making wood-cuts 105, 117, 204, and 211 do duty a second time over slightly different letter-press, as Figs. 326 241, 228, and 248 respectively.

To sum up all, we think that this handsome volume is one which the advanced student and working microscopist cannot afford to do without; but, at the same time, we fear that the novice who consults it as a guide in his elementary studies will often turn from its pages with disappointment and regret.

ON CEREBRIA AND OTHER DISEASES OF THE BRAIN. By CHARLES ELAM, M.D. Lond., etc. 8vo, pp. 142. Philadelphia, Lindsay & Blakiston, 1872.

Dr. Elam states that cerebritis uncomplicated with meningitis is a disease "unrecognized and undescribed," some authors even doubting its existence. In fact, all inflammatory affections of the brain have, in the opinion of our author, failed to receive from recent writers the attention they deserve: he has therefore written this little work with the object of giving his own experience in regard to them.

The chapter on tubercular meningitis is an example of the manner in which the book is written. It consists of a single case of the disease, in which recovery took place, and of another case which was not meningitis at all,—simply an instance of gastric disturbance with brain-symptoms.

In regard to cerebritis unaccompanied by meningitis, there is no doubt that Niemeyer was aware of its existence, although he does not describe it at length, and speaks of all forms of encephalitis as being rare; and Aitken, in his "Practice of Medicine," says, "While dissection demonstrates the fact that inflammation may exist either in the brain alone or in the membranes alone, yet, clinically, it is found that meningitis generally complicates cerebritis." Reynolds believes that inflammation of the brain is never met with without inflammation of its membranes.

Cerebria is defined by the author as "a spontaneous, acute, general inflammation of the substance of the brain, uncomplicated with meningitis," and he has given this name in contradistinction to cerebritis, which he says has so long been described as a compound of inflammation of the brain and its membranes.

The account of the disease appears to be based on but three cases; at least there is no reference to any others, and its most marked characteristics are said to be its uniform beginning and end. It begins with vomiting, and ends with death. In no instance was there any evidence of suppuration. In the first case, the only departure from health was the brain-substance being "closely dotted with red points, the gray matter darker than usual, and the white slightly rosy." In the second, the brain was so much softened that it could not support its own weight; but the microscope showed no pus. The post-mortem, in the third case, was similar to that in the first. In neither of these was any microscopic examination made.

The observations on the study of cerebral affections, and on the circulation of the brain, are of interest, and show considerable original thought; but our limited space will not allow us to discuss them.

JOURNAL OF THE GYNÆCOLOGICAL SOCIETY OF BOSTON. Monthly. Edited by WINSLOW LEWIS, M.D., HORATIO R. STORER, M.D., and GEORGE H. BIXBY, M.D. Vol. vi., January to July, 1872, pp. x., 480.

This journal is devoted to the consideration of the diseases peculiar to women. It includes reports of the meetings of the Gynæcological Society of Boston and the Obstetrical Society of Philadelphia; the latter extracted from the *American Journal of Obstetrics*. A large number of the articles have been contributed by members of the first-named society, but a welcome has been extended to every communication treating of subjects within the scope of the society. Some of these articles are of great practical value, among which we may mention a case of hysterical insanity depending upon cystic disease of the ovaries and extensive inflammation of the cellular tissue of the pelvis. The only symptoms during life were arrest of the menstrual secretion, and a phantom tumor; the latter was for a long time considered to be hydatids of the liver. The true state of the case was ascertained only by autopsy.

A history of Uretero-Uterine Fistula, by Drs. Wilhelm Alex. Freund and Ludwig Joseph, of Breslau, translated from the German by Mary Safford, (*homœopathic*) medical student at Breslau, contains more information on this form of fistula than can be found in any other work.

The society, in compliance with an invitation received from Dr. Henry A. Martin, paid a visit to the farm of the latter at Boston Highlands.

Fifty pages of the journal are given to a description of the methods, results, and comparative effects of animal virus, first remove, and long humanized, with respect to inflammatory consequences, eruptions, the danger of conveying blood-poisons, etc. Dr. Martin's virus can be obtained only from himself, as he supplies no agents or dealers with it.

BOOKS AND PAMPHLETS RECEIVED.

Outlines of Surgery and Surgical Pathology, including the Diagnosis and Treatment of Obscure and Urgent Cases, etc. By F. Le Gros Clark, F.R.S., etc. Second Edition. Crown 8vo, pp. 350. Philadelphia, Lindsay & Blakiston, 1872.

What Physiological Value has Phosphorus as an Organismal Element? An Essay to which was awarded the Prize of the American Medical Association for 1872. By Samuel R. Percy, M.D., etc. 8vo, pp. 56. Collins, Printer.

Nebulæ, Comets, Meteoric Showers, and the Revelations of the Spectroscope regarding them. By Prof. H. Schellen and others. Coral and Coral Islands. By Prof. J. D. Dana, of Yale College. (Half-Hour Recreations in Popular Science, No. 5.) Small 8vo, pp. 47. Boston, Estes & Lauriat, 1872.

Annual Report of the Surgeon-General of the United States Army, 1872.

GLEANINGS FROM OUR EXCHANGES.

TRAUMATIC ICTERUS.—M. Verneuil (*Le Mouvement Médical*, Sept. 14, 1872) recently announced to the Académie de Médecine the following propositions:

1. Icterus may be developed as a consequence of a traumatic lesion, an accidental wound, or a surgical operation, whether affecting the liver or some organ more or less remote.

2. In the first case there is traumatic icterus properly so called, or direct; in the second case it is indirect.

3. This latter form comprises two varieties, clearly distinct in causes, course, prognosis, and pathogenesis.

4. The first variety, *pyæmic* icterus, is a symptom of purulent infection; it is due to septicæmic alteration of the blood, with or without the occurrence of metastasis. The second variety, *reflex* icterus, not pyæmic, is doubtless owing to perverted innervation.

5. Neither direct traumatic icterus nor the pyæmic variety implies any previous change in the liver. Organic lesion of this gland seems, on the contrary, to be a predisposing condition necessary to the production of the reflex variety.

6. The diagnosis between these three forms is generally easy. For the first, it suffices to recognize the lesion, direct or indirect, of the liver; for the second, we have the whole train of pyæmic phenomena; for the third, we must investigate, above all, the circulatory organs and the thermometric changes.

7. Although generally grave, the prognosis of icterus occurring consecutively to lesions varies much, according to their nature and complications; the severity of the direct traumatic form depends upon the effect of the primary cause upon the gland. Pyæmic icterus is, and always must be, a very serious affair, like the general disorder of which it is merely a symptom. Reflex icterus is comparatively innocent, except where the previous disorder is of a nature necessarily fatal.

8. Reflex icterus does not seem to modify unfavorably the process of repair of the injury causing it.

9. This condition belongs to the great class of "deutéropathies traumatiques éloignées" (remote traumatic secondary lesions). It constitutes one of their rarest forms. Judging from the meagreness of the reports concerning it, its history can only be completely made out from the results of fresh investigation.

DETERMINATION OF THE AMOUNT OF SUGAR IN DIABETIC URINE BY THE DIFFERENCE IN THE SPECIFIC GRAVITY BEFORE AND AFTER FERMENTATION (W. Manassëin, *Deutsch. Archiv für Klin. Med.*, Bd. x., S. 73–88; quoted from the *Central-Blatt für Med. Wiss.*, No. 35, 1872).—The experiments of Manassëin corroborate the statements of Roberts (Memoirs of the Manchester Lit. and Phil. Soc., 1861), that the amount of sugar in diabetic urine may be determined in the manner indicated by the title of this article. Roberts found that for every difference of 0.001 in the specific gravity before and after the process of fermentation, we must use a multiplier, 0.23, in order to obtain the percentage of sugar in the urine. Manassëin suggests 0.219 as a multiplier, instead of which, however, he prefers the use of a divisor, 4.56, for the calculation of the amount of sugar. With this he divides the difference in the specific gravity multiplied by 1000, and obtains the percentage of sugar directly. For example, let the

Specific gravity before fermentation be . .	1.0298
" " after " " . .	1.0055
The difference	0.0243

Multiply this by 1000, and

Divide by . . . $4.56 = \frac{24.3}{4.56} = 5.33$,

the percentage of sugar.

The temperature which most speedily accomplishes the fermentation (usually in twenty-four hours) is 20° to 24° C.

The cheapness of this process is one of its advantages, but the length of time, eighteen to twenty-four hours, required for its completion is objectionable in many cases. The method is applicable to diabetic

urine largely diluted with water; hence it may be put down among the delicate tests for sugar in urine.

Treatment of Fissure of the Anus (*Med. Times and Gazette*, June 8, 1872).—A lecture on this subject, by Dr. Dolbeau, is reported by Dr. Osborne Powell. He observes that each evacuation of the bowels is accompanied by a feeling of something cracking, followed by intense pain; nevertheless, in many instances no fissure can be found, even after the most careful and minute inspection. He consequently regards it as of the nature of neuralgia. It commonly occurs between the ages of eighteen and thirty, and most frequently in women. In the treatment the first thing to do is to abolish the muscular element. Récamier, whose name is inseparable from the history of this malady, well comprehended that the fissural lesion is an element without importance, and he cured several patients by what he termed *cadenced massage*. Chloroform was then unknown. He had the patient held by some strong assistants, and he introduced first one finger, then another, and so on, until he had passed his whole hand into the rectum; he then closed his fist, and drew his hand from the intestine. This was a most rational operation, and the employment of chloroform in the present day permits us to practise it in a much less barbarous manner. Thus, the patient being put under the influence of chloroform, the surgeon introduces his two thumbs into the rectum, and endeavors to bring them in contact with the two ischia; at that moment one hears a strong cracking noise, and the operation is finished. The first stool after the operation is painful, but this pain is simply the result of the region being contused, and does not in the least resemble the pain which characterized the spasmodic attacks. The succeeding stools are without any pain, and the cure is assured.

Fischl on Pneumonia Migrans (*Prager Vierteljahrsschr.*, Bd. 114, S. 112–123).—Schiffer calls attention to this article, in a review in the *Central-Blatt für Mediz. Wiss.*, No. 35, 1872. It appears that up to the present time only Waldenburg and Wiegand have contributed accounts of this rare affection; the former relating one case, and the latter two cases. The chief characteristic of the disease consists in many parts of the lung being successively attacked by the croupous process, the portions first attacked healing as the disease advances to the healthy parts.

The course of this disease may be anatomically continuous, as in the case of Waldenburg, where the disease began as a pneumonia dextra inferior, passed upwards through the entire right lung, attacked the apex of the left lung, and by steady advances reached the base of the lung on the left side. This course was passed over *twice* by the disease in the same individual. On the other hand, there may be no such regularity in the course pursued by the disease, and the same lung may be attacked first in one part and then in another. In any event the disorder is very tedious, and, as Waldenburg has observed, highly suggestive of erysipelas migrans. The case related by Fischl, of a strong woman, 36 years old, showed the last-mentioned characteristics. When this patient was first seen, fourteen days after the beginning of the disease, the infiltration was discovered in the left lung, upper part; two days later the infiltration was found at the base of the right lung; a few days subsequent to this the disease was found in the infraclavicular region, left side, etc. Twice, parts were attacked which had been already affected. The infiltrations were quickly developed, without initial chills, and were very quickly absorbed. The disease lasted six weeks, with continuous fever, and the sputa continued of a catarrhal nature during the entire course of the affection, with at no time the appearance of any blood in them.

Treatment of Pemphigus.—Mr. Hillairet (*Le Mouvement Medical*, Sept. 14, 1872), reasoning from the analogy between this disease and burns of the second degree, believes that a similar treatment—dressing with cotton-batting (*ouate*) and lime-water liniment—will be found to answer well in both.

MISCELLANY.

Another Quadruple Amputation.—In our issue for Nov. 16 (Miscellany, p. 110) we quoted from a foreign exchange an account of a quadruple amputation by Dr. Begg, of Dundee, which was said to be the only one on record in which all four extremities had been removed. Dr. Woodhull, U.S.A., has been kind enough to call our attention to a case detailed in Circular No. 3, U.S.A. War Department, S. G. O. (Case DCXII., p. 216), in which "a similar set of operations was performed by Acting Assistant-Surgeon Alfred Muller, at Fort Ridgely, Minnesota, Jan. 13, 1866. This antedates the Scotch operation, and the patient appears to have been in a more deplorable condition—if this were possible—than the other, in view of the condition of the nose and patellæ." The operation in Dr. Muller's case was done for frost-bite, on the nineteenth day; the tip of the nose had perished, and the patellæ subsequently exfoliated. "The probable inability to use artificial limbs is a misfortune that gives to the American a very different termination from that of the British case. This same case—the American—was also briefly published in 1867, on pp. 522–3 of the Catalogue of the Surgical Section of the Army Medical Museum."

Jewish Mortality.—According to Dr. Stallard's work on "London Pauperism," the mortality of Jewish children under five years of age is much less than among other children. There is no hereditary syphilis, and scarcely any scrofula. The mother engages in no employment that takes her away from her children. From one year to five the Jews lose only ten per cent., while the Christians lose fourteen. The average life of the Christian is thirty-seven years,—of the Jew, forty-nine years. Beyond sixty years, only a quarter of a Christian population will be alive, but a quarter of a Jewish population will exceed seventy-one years. In Prussia the Christian population requires fifty-one years to double itself, but the Jewish population will double itself in forty-one years.

Prizes.—The Royal Institution of Science, Literature, and Arts, in Venice, offers a medal of the value of three thousand francs (£120), to be awarded in 1874 to the author of the best essay on the following subject: "The advantages derived by the medical sciences, especially physiology and pathology, from modern discoveries in physics and chemistry; with a retrospective view of the systems which prevailed in medicine in past times." The competition is open to foreigners; and the essays may be written in French.

A Good Example.—It will be remembered that a few weeks since the Reverend Canon Charles Kings-

ley, in his presidential address to the Birmingham Midland Institute, recommended with great earnestness and eloquence the teaching of the art, and also the encouragement of the practice, of preserving health. We have just learned from the Birmingham papers that this good advice has been followed by an anonymous benefactor investing £2500 to establish a professorship on that subject.

THE Medical Society of London offers the prize of the Fothergillian gold medal for 1873, of the value of twenty guineas, for the best essay on cancer. The subject for 1874 is the therapeutic means for the relief of pain. The prize is open for universal competition. Essays, *not in the handwriting of the author*, must be forwarded to the Society's rooms on or before the 1st of November next preceding the 8th of March in the years 1873 and 1874 respectively.

AT a meeting of the Medical Society of Victoria held in June last, the following collection, taken from the stomach of a lunatic upon whom a post-mortem examination had been made, was exhibited :—Twenty-five pebbles, sixteen pieces of glass, twelve nails, one screw, two bones, a button, five bits of tin, a peach-stone, six fragments of a pipe-stem, and a whole cutty pipe. The cutty pipe was found fixed in the ileo-cæcal valve.

MEDICAL MICROSCOPICAL SOCIETY.—A new society has been proposed, and is probably by this time in operation, in London, with the above name. A writer in the *Medical Times and Gazette* says, and we should think justly, that it would have been better had the medical members of the already existing Microscopical Society constituted themselves into a medical section.

ANOTHER NEW JOURNAL.—The prospectus of a new monthly, to be called the *Central New York Medical Journal*, has been issued by Dr. Ely Van De Warker, of Syracuse, N. Y. It is to be published subject to the approval of the Medical Association of Central New York, upon a guarantee of a subscription-list of three hundred.

A CAUTION.—A surgeon of Leominster, England, Mr. David Davies, has been fined £1 and costs for having twice kissed a lady who came to consult him as to the beating of her heart, which, he declared, beat "naturally enough."

ACCORDING to the census of the German empire, which was taken in December last, the total population (including Alsace and Lorraine) amounts to 41,058,000. The females exceed the males in the empire by no less than 768,000.

THE number of paupers relieved in England and Wales at the end of July last was 10.6 per cent. less than at the corresponding period of the year 1871.

THE Augusta Medical College of Georgia has been made the Medical Department of the University of Georgia ; a compliment well bestowed and fully merited.

DR. W. R. GIBBES, of Columbia, has been elected Professor of Anatomy and Surgery in the University of South Carolina, in place of Dr. Darby, resigned.

DR. GEORGE COCHRAN, health officer of Brooklyn, died of congestion of the lungs, at his residence in that city, on the 19th ult.

DR. WARREN STONE, a distinguished surgeon of New Orleans, died in that city on the 6th inst., at the age of sixty-five.

DR. SAMUEL WILLEY, one of the oldest practitioners in St. Paul, Minnesota, died recently.

MORTALITY OF PHILADELPHIA.—The interments reported at the Health Office for the week ending Dec. 7, 1872, were 302 ; 165 adults, and 137 minors. 23 were of bodies brought from the country ; making the mortality of the city 279. Among the causes of death were :

Consumption of the Lungs	39
Other Diseases of the Respiratory Organs	41
Diseases of the Circulatory Apparatus	20
Diseases of the Brain and Nervous System	52
Diseases of the Digestive Apparatus	16
Zymotic Diseases (Scarlet Fever 5, Hooping-Cough 6)	17
Typhoid Fever	6
Casualties	8
Cancer	9
Debility (including "Inanition" and "Marasmus")	31
Still-born	26
Old Age	14

(The interments reported for the week ending Dec. 9, 1871, were 470.)

THE meteorological record kept at the Pennsylvania Hospital was as follows :

	THERMOMETER.		BAROMETER.
	Max.	Min.	(2 P.M.)
Dec. 1	34.5°	18.0°	30.24 in.
" 2	48.5	36.5	29.99 in.
" 3	45.0	35.0	30.20 in.
" 4	40.0	35.0	30.39 in.
" 5	38.0	33.5	30.36 in.
" 6	45.0	28.5	30.39 in.
" 7	39.0	32.5	30.37 in.

OFFICIAL LIST

OF CHANGES OF STATIONS AND DUTIES OF OFFICERS OF THE MEDICAL DEPARTMENT U. S. ARMY, FROM NOVEMBER 26, 1872, TO DECEMBER 2, 1872, INCLUSIVE.

ALEXANDER, R. H., SURGEON.—Assigned to duty as Post-Surgeon at Fort Vancouver, Washington Territory ; relieving Surgeon J. H. Bill, U.S A. S. O. 154, Department of the Columbia, Nov. 14, 1872.

JAQUETT, G. P., ASSISTANT-SURGEON.—Granted leave of absence for twelve days. S. O. 208, Department of the Platte, Nov. 22, 1872.

HUNTINGTON, D. L., ASSISTANT-SURGEON.—Assigned to duty at Camp Harney, Oregon, but, owing to lateness of season, to proceed to Fort Stevens, Oregon, for temporary duty at that post S. O. 155, Department of the Columbia, Nov. 15, 1872.

PHILLIPS, H. J., ASSISTANT-SURGEON.—Granted leave of absence for thirty days, and leave to go beyond the limits of this Department. S. O. 153, Department of the Columbia, Nov. 13, 1872.

STYER, CHARLES, ASSISTANT-SURGEON.—Granted leave of absence for four months from December 1, 1872. S. O. 309, War Department, A. G. O., Nov. 29, 1872.

WEISEL, D., ASSISTANT-SURGEON.—Granted leave of absence for thirty days. S. O. 306, War Department, A. G. O., Nov. 26, 1872.

MATTHEWS, WASHINGTON, ASSISTANT-SURGEON.—Assigned to temporary duty at David's Island, N Y. Harbor. S. O. 228, Department of the East, Nov. 25, 1872.

ORIGINAL LECTURES.

CLINICAL LECTURES ON PROLAPSE OF THE WOMB.

BY WILLIAM GOODELL, M.D.,

Physician-in-Charge of the Preston Retreat; Clinical Lecturer on the Diseases of Women and Children in the University of Pennsylvania.

LECTURE II.

(Continued from page 162.)

GRANTING, then, that this elongation arises in the main from traction, and not primarily from any constructive energy inherent in the cervix; what are our resources for its cure? Could I put this woman to bed for a few weeks, and thus relieve the cervix from its own dead weight and from that of the vagina and bladder, it would shrink back very materially, but not to the standard length of the healthy womb. It would act, as I have before said, precisely like an over-stretched rubber band. I might then adjust some suitable pessary which would keep the prolapsing organs in their proper positions. Unfortunately, the poverty of this class of patients renders such a treatment inadmissible. At best, the womb is too ductile, the vagina and perineum too lax, even when contracted by appropriate operations, to render this treatment other than tedious and unsatisfactory.

The desideratum here is something that can furnish a support to the unstable pelvic organs, and, at the same time, consolidate the ductile womb by giving a fillip to the now dormant process of involution. Both indications are often met by the mere amputation of the vaginal portion of the cervix, although in bad cases the former may further demand the constriction of the vulval opening. From a misconception of the nature of this disorder, Huguier recommends an unnecessarily severe and dangerous operation, by which the whole vaginal portion is removed, and with it a conical core of the supra-vaginal portion. You will naturally ask, "How can the removal of an infra-vaginal slice cure a supra-glandular elongation measuring three or four inches?" I shall reply, first, by two illustrations: after the ablation of a uterine polypus, its pedicle, however long and broad, will disappear; an elongation of the uvula is curable by snipping off merely its tip. In the second place, the hemorrhage during the operation, by depleting the womb, causes shrinkage; the rest in bed furthers this contraction; whilst the prolonged suppuration necessary for the repair of an open wound sets up so alterative an action as will carry out the process of shortening and finally consolidate the whole uterine body. Once more, this operation lessens the weight of the cervix, and establishes a retrogressive metamorphosis of the subinvoluted vagina and of its thickened mucous investment, giving, thereby, tonicity and stability to those parts.

One danger attaching to this operation is that of hemorrhage, but with care this can be avoided. Such accidents as peri- and para-metritis, tetanus, and septicæmia will occasionally happen, but not with a frequency greater than in any other surgical operations upon the cervix. To avoid the loss of blood, and to obtain a deeply granulating wound, the amputation is usually made with the chain- or wire-écraseur, or by the galvano-caustic loop. But, whatever the instrument, the operation is always attended with the risk of invading the bladder and especially the retro-uterine pouch. Hence, I should advise you, whenever you can closely watch your patient, to use the knife or the scissors. For, thereby, not only can you remove with greater safety a larger slice of the cervix, but also can, in case of this accident, bring together, by metallic sutures, the cleanly-cut edges of the vesical or peritoneal wound. Whereas no union would be likely to take place were the edges crushed by the écraseur or seared by the galvano-cautery. This mishap has happened to the most skilful operator; but, if every case has been reported, no great fatality attends it. Whenever amputation with a cutting instrument is resorted to, it will be safer first to transfix the cervix, as high up as prudent, with a long straight needle; then to place above this, as a tourniquet, the loop of an écraseur, and, finally, to slice off all that portion of the cervix on its distal side, making the incision between it and the needle. If, upon loosening the loop, any smart bleeding occurs, you may either sear the wound with the hot iron, or plug up the vagina; for, to catch up and tie a vessel in a hypertrophied cervix is no easy task. The only sure way of using the ligature is to transfix deeply each bleeding point with a curved pin, and then to ligate under it the raised-up flesh *en masse;* the pin being left *in situ* for several days.

I have described this operation somewhat fully, because, although it offers several advantages, I shall not perform it this morning, but shall use the wire-écraseur. My reasons for this seeming inconsistency are, that the excessive heat of the weather forbids the use of the tampon except as a sheer necessity, and that I shall not to-day be within call should a secondary hemorrhage take place. After placing our patient in the lithotomy position, I first catch up with a forceps the cluster of vegetations dangling from the meatus of the urethra, and snip off its base with the scissors. To prevent its otherwise sure return, I rub the raw surface with the frayed end of a match moistened with fuming nitric acid, and with a little olive oil decompose any excess of the acid. I next draw off the urine, and at the same time measure, with the catheter, the depth of the vesical pouch, and also sound the bladder for stone. In order to make myself easy on the score of wounding the bladder, I shall follow Huguier's example, and explore that organ with my finger. By gently opening the blades of a dressing-forceps in the urethra, I have, in a few minutes' time, so dilated this short and elastic canal that it will now permit me to coax in my little finger. Note how

low its tip reaches,—certainly not more than half an inch from the apex of the everted cervix. So far, good! We have accurately defined the lower boundary-line of the bladder; but very unfortunately there are no diagnostic criteria for ascertaining the depth of the retro-uterine fold. Usually, this fold does not descend so low as the pouch of the bladder; but this rule is not invariable, and the peritoneal cavity will occasionally be opened in spite of the greatest care. Guided by the tip of my little finger inside of the bladder, I now transfix the cervix antero-posteriorly by a sharply pointed skewer, entering it just below the lower margin of the bladder, and slanting it upward and backward so that its point may emerge somewhat higher up on the opposite side. The bladder is, therefore, safe, whilst the pouch of the rectum is so small, and so far from the course of the skewer, as also to be out of harm's way. Could this be affirmed as positively of the peritoneal fold, the operation of itself would be without any hazard whatever; but, with regard to that, much must be left to chance. It remains now to adjust the wire loop of the écraseur, and this is done by slipping it over the cervix and close up to the distal side of the skewer. I give a few turns of the screw; and now see how bloodlessly the whole vaginal portion of the cervix has been amputated.

Some of you may perhaps wonder why the écraseur was not used without the skewer. There is a good reason for this: Whenever the wire or the chain of an écraseur begins to bite into living flesh, it tends not only to slip in the direction of least resistance, but also to drag into its loop the more relaxed tissues of that side. Now, since the vaginal portion of the cervix is clubbed and tuberous, the direction of least resistance and the looser tissues lie above the surgical neck. Hence, unless guarded by the skewer, the loop might slip upwards and pinch off a piece of the bladder or of the peritoneum.

Our patient will now be put to bed, where she must stay for at least two weeks. Should secondary hemorrhage take place—which is improbable—I shall be forced either to sear the raw surface with the hot iron, or to plug up the vagina. As soon as pus begins to form, the vagina will be washed out several times a day with carbolized injections. If left to itself, the wound will not cicatrize under four weeks; but the healing process can be hastened by an occasional touch with the nitrate of silver.

This operation will most likely result in our patient's cure, so far as the elongation of the cervix is concerned,—that is to say, after the lapse of five or six weeks her uterine cavity will not measure over three inches in length. But it may not prevent more or less prolapse of the relaxed vagina and bladder, and another operation will perhaps be needed to repair the torn perineum. Some surgeons advise in every case an operation either for contracting or shortening the vaginal canal or for narrowing its outlet; but this is by no means necessary. Whenever the fundus has barely sagged down, I believe that, whatever the degree of cervical elongation, the removal of the vaginal portion will alone effect a cure in the majority of cases. For the same stays which have hitherto sustained the fundus will afterwards, through the medium of the now contracted and consolidated cervix, sustain also the vagina and bladder. On the other hand, whenever the fundus is found to be displaced to any marked degree, and especially when wholly extruded,—as in Fig. 3,—then, in addition to the amputation of the cervix it will be necessary either to lengthen the perineum and at the same time narrow the outlet by the operation of episio-perineorrhaphy; or to perform some one of those operations for contracting the vaginal canal which you will find described in Dr. T. G. Thomas's excellent work.

A Lumbricus discharged through an Abscess about the Hip-joint—Recovery (*Lancet*, Nov. 30, 1872).—The following curious case occurred in the Mansfield Workhouse Infirmary in May last:

J. W., aged thirteen, was suffering from strumous disease of the hip-joint, but able to get about on crutches. The usual abscesses kept forming and bursting about the joint: one abscess, however, after bursting, discharged as part of its contents a large lumbricus, fully eighteen inches long, and coiled upon itself. How did it get there? At any rate, the wound healed rapidly, and the boy's health improved considerably.

ORIGINAL COMMUNICATIONS.

PARESIS.

Read before the Northern Medical Association of Philadelphia, September 27, 1872.

BY ANDREW K. MINICH, M.D.

THE term paresis is from the Greek παρημι—"I relax," and was introduced by Saloman, a Swede, as a substitute for "general incomplete paralysis of the insane,"—a very unwieldy term, and only partially expressive of the disease under consideration.

Since the days of Calmeil, one of the earliest writers on paresis, it has been recognized as existing in three distinct stages. The symptoms in the first stage are various, and chiefly mental.

There is often a disposition to wander from home, to neglect every-day duties, and to commit petty thefts. Generally there is a change in the morals of the patient; a religious man may become profane, and *vice versâ*. Undue importance is attached by the patients to themselves. They imagine they have become wealthy, hold honorable positions, and express determinations to erect churches, colleges, establish new lines of railroads, or project other schemes of great magnitude. The voice in this stage is changed to a slight stutter or stammer.

The more marked symptoms in the second stage are disturbed locomotion and difficult articulation. The walk in this stage is peculiar. Dr. Sankey has well observed "that there is in health a kind of expression in a person's gait, from which we may almost divine what kind of errand or business a man is upon." A man walking for exercise has a gait differing from one walking to attend to business. The two chums, with arms hooked, as they saunter along, contrast in a marked manner with the excited broker on Wall Street. The gait of a person with paresis is that of a man walking "without a definite object;" and later in the disease, walking becomes more a "matter of business." The feet are raised but slightly, are widely separated, and fall flat upon the floor. His arms are to him what the balancing-rod is to the tight-rope walker,—a means of maintaining his equilibrium. All the muscles seem affected. Any act requiring muscular interference is attended by phenomena due to a want of harmony in their action. To compare the movements and actions of a paretic to a drunken man would not be amiss, save that the paretic is cautious and deliberate, the drunkard "reckless and garrulous." Later in this stage, walking is very difficult, and, from the labor spent upon its performance, a looker-on might well surmise that the performer was making it a specialty. The articulation is drawling and difficult, often the syllables are run into each other, and mumbling takes the place of articulate sounds. Twitching of the muscles around the mouth is common. The tongue when protruded is very tremulous, and is quickly drawn back into the mouth, in spite of urgent requests to the contrary. Grinding of the teeth is frequently indulged in,—a most unpleasant symptom to those within hearing-distance. It grates sufficiently hard upon the ear to have such a symptom show itself in a bedridden patient, but to see and hear a man, with a confused stare, with reason dethroned, wandering around grinding his teeth simultaneously with every short step he takes, is almost beyond endurance. The intellectual, moral, and motor faculties are all more or less influenced. The senses of touch and taste are impaired to a more marked degree. If a paretic is asked concerning health, the reply generally will be, "first-rate," "bully," "beautiful," or some other brief expression. I would lay special stress upon the first of these answers, for almost invariably he will be "first-rate." The conversation of the paretic in this stage, as well as in the first, is not disconnected. Fixed delusion is very rare. His ideas bear the impress of change; they are not fixed like those of the monomaniac; *now* he may be worth a hundred thousand dollars, and cashier of some bank, and one hour hence be a millionaire and chief executive of the nation. He grows *richer*, but never *poorer*. "Excelsior" seems to be his motto. The symptoms, then, in this stage are, —a want of power to control perfectly the motor, intellectual, and moral faculties.

The third stage manifests its advent by dementia, and inability to stand upright or to execute any movement requiring the use of more than a few muscles. This muscular feebleness is more marked in the morning. In this stage the utterance is thick, and often unintelligible. The muscles are constantly twitching. The knees of the patient when sitting shake like those of a man suffering from a chill. His teeth chatter, he looks cold, although he tells you that he is "first-rate." Urine and fæces are passed apparently unconsciously. The urine in all the cases that I have observed was extremely phosphatic, not alone in this stage, but also in the second, although somewhat less in the latter. The temperature, according to Mr. Dodge, resident student at the Philadelphia Hospital, who carefully observed it at my request, was found to vary from one-half to one degree, according to the time of day. In the morning it was, in confirmed cases, one hundred, to one hundred and five-tenths degrees. In the evening the mercury invariably rose to one hundred and one degrees. The appetite is good, almost voracious, up to the time of dissolution. This, no doubt, assists in prolonging the life of the patient when to the observer death seems imminent. I saw poor John Ambrose, a fine minstrel, whose voice once charmed enthusiastic audiences, literally, like Herod of old, eaten by worms, numbers of which, thick and fat, crawled from his anus and large putrefying burrowing sores. He was a mass of rottenness when death entered his chamber. He partook of a hearty breakfast but a few hours beforehand.

Picking at the bedclothes, and tearing them into shreds with hands and teeth, afford hours of employment to the bedridden paretic. Irritation applied to the soles of the feet produces immediate reflex action. Epilepsy and epileptiform convulsions often occur. Sometimes the patient is seized by apoplexy: indeed, not a few meet their death in this way.

Bed-sores are prone to occur in this stage, their formation being due to the patient's continued supine position, and to the frequent presence of irritating matter. The symptoms then characteristic of paresis are, mental derangement, difficult articulation, and disturbed locomotion.

The cause of this strange malady is still wrapped in mystery. Excess in some form upon the part of the patient, at some period of life, no doubt, lies at the bottom of this disease, as of so many others. The histories of cases confirm this belief. Medical science cannot, however, explain why it is that one person using alcoholic drinks as a beverage will, as a consequence, die of a cirrhosed liver, and another of a cirrhosed brain.

The diagnosis of paresis is not difficult. It may, however, be confounded with muscular atrophy, lead- and mercurial palsy, chronic alcoholism, and certain cases of spinal paralysis. It differs from general muscular atrophy in this, that the latter is free from mental derangement. Symptoms of mental derangement, however, might occur in a case of muscular atrophy. In such a case the peculiar form of insanity in paresis, and the condition of the muscles, would serve to distinguish the two affections. Lead- and mercurial palsy are less likely to be confounded with paresis. Lead-palsy manifests itself more locally. The imperfect locomotion is more circumscribed. The wrists are chiefly affected, and the muscles of the affected parts become wasted. The condition of the gums and the absence of delirium in lead-palsy would also serve as distinctive features. Mercurial palsy can also very readily be distinguished. The peculiar trembling of the hand does not occur in paresis, neither is there mental derangement in mercurial palsy. Chronic alcoholism, the result of an abuse of alcoholic drinks, in which the motor and mental functions are affected, is more likely to be mistaken for this disease by a casual observer. This, however, is only true of decided cases of a chronic nature. They present distinctive characteristics. According to M. Thomeuf, the form of mental symptoms usually presented in alcoholism "is a kind of melancholia, with exaggerated fears, frights, delusions of being followed or watched, or of being accused of guilt. The paretic is never afraid, is not melancholy, generally entertains grand ideas, and is never unwell." All those that came under our own observation confirm this statement of Thomeuf. All would express themselves as being "first-rate," and this in tones, to use the words of Dr. Bucknill, "in which could be detected the signs of incurable disease." The appetite in alcoholism is deficient; that of the paretic can scarcely be appeased. Epileptic and epileptiform convulsions occur in paresis; delirium tremens in alcoholism. The latter is curable; the paretic always dies. Certain cases of spinal disease in which the paralysis is more or less general may be complicated with delirium, and thus be mistaken for paresis. The history of the case, the condition of the spinal cord, and the nature of the delirium would serve to point out the true diagnosis.

The pathology of this strange malady has been a fruitful source of discussion in later times. Observers do not agree as to its nosological position. Some view it as a form of mania upon which are engrafted paretic symptoms. This view is refuted by the fact that symptoms of paresis never occur in cases of chronic mania. Others maintain that paresis may exist without paralytic manifestations, and recognize it by the name of "ambitious mania." Ambitious mania, though it resembles paresis in the character of its delusions, is a separate affection. Paresis is ambitious mania, but it is something more. We have seen cases of chronic mania, of simple insanity, without any apparent physical disturbance, that even now pace the wards and strut along the corridors of the Insane Department of Blockley Hospital, whose imagination knows no limit. One sports with millions, another is the Saviour of the world, while several proudly march along, conscious that the world recognizes them as ruling monarchs. The majority of observers, however, look upon paresis as a separate affection,—a disease *per se*.

It presents characteristics similar to other affections. It is influenced by locality. Dr. Grey makes mention of the fact that in the Edinburgh Asylum there are usually to be found from twenty to twenty-five cases, while Montrose Asylum, about twenty-five miles distant, and containing about three hundred patients, has none. The disease is more prevalent in the eastern and northern parts of America than in the southern and western. Males are much more subject to paresis than females. Statistics prove the proportion to be about seven of the former to one of the latter. Age exerts an influence. Most patients are between the ages of thirty and forty years. Cases occur occasionally, however, to prove that neither the young nor aged are wholly exempt. All paretics are insane. Insanity is one of the principal symptoms. This mental derangement is manifested by an exalted imagination,—very rarely presenting itself in a different form. Respecting the pathology of paresis, some view it as an inflammation. M. Parchappe says, "all facts afforded by pathological research agree in confirming the inflammatory nature of the characteristic lesion of the cortical substance of the brain." M. Belhomme expresses a belief that "paresis is an encephalitis of a peculiar kind."

The post-mortem appearances are not constant in every respect. Sometimes there is softening, sometimes the brain is abnormally firm. This difference is probably due to the comparative duration of the disease. The arachnoid and pia mater generally present traces of inflammatory change. The microscope has detected in most cases a varicose condition of the capillary vessels of the cortical substance, and also a marked increase of its connective tissue. This increase of the connective tissue of the cortical substance is the most constant of the morbid conditions. It is, pathologically speaking, a cirrhosis of the cortical portion of the brain, the result of a slow inflammation. There is no doubt that the disease is cerebral. The impaired locomotion is not owing to muscular paralysis, but to something interfering with co-ordinate

action. The constantly cheerful answer which the patient ever gives in regard to his or her health is due to one of two conditions, or to both. It may be but the result of a feeble conception. The brain in its diseased condition, with its cells compressed by the superabundant connective tissue, may be incapable of taking cognizance of the body's condition. The fault does not seem to be in the afferent or efferent nerves. They faithfully transmit impressions, as is shown by the immediate reflex movements that take place in response to any irritation applied to the surface of the body. It may be that even though the patient's brain is capable of appreciating pain and poverty with their accompanying shadows, yet his peculiar form of insanity, his ambitious mania, his radiant line of thought, will scatter those shadows as the wind scatters the leaves of autumn. His judgment has fled, and as his idea of wealth and splendor is not corrected by his bed of straw and lonely cell, in like manner his idea of personal comfort and perfect health may not be corrected by painful sores and fatal disease.

The prognosis is always unfavorable. A few cases of recovery are reported. It may be that the diagnosis was not correct. Recovery, it is stated, was preceded by a general breaking out of boils.

Of the treatment very little can be said. Aside from attention to the general comfort and cleanliness of the patient, it consists merely of a "meditation on death;" of reading from time to time the inscriptions upon the mile-stones as our buoyant patient totters along the downward road to meet his inevitable doom. He is an inmate of that ward above the entrance of which is written, "For Incurables,"—a department which, through the deeply-searching spirit of modern science, may ere long, we hope, be made vacant, and the unfortunate paretic among the rest be restored to health, and ushered from that abode of fate.

NEW METHOD OF PRESERVING TUMORS AND CERTAIN URINARY DEPOSITS DURING TRANSPORTATION.

BY JOSEPH G. RICHARDSON, M.D.,

Lecturer on Morbid Anatomy in the University of Pennsylvania; Physician in the Out-Patient Department of, and Microscopist to, the Pennsylvania Hospital, etc.

Read before the Biological and Microscopical Section of the Academy of Natural Sciences, and recommended for publication in the Philadelphia Medical Times.

IN the early days of medical microscopy, partly because all revelations of the science were looked upon by most practitioners with suspicion or positive distrust, partly, I presume, on account of real unskilfulness among its students, microscopic examinations were rarely called for, and there was little need of devising plans for securing the portability of specimens. At present, however, when the value of the microscope, not merely as an aid, but even as the most reliable guide for diagnosis, prognosis, and treatment, in many forms of disease, is becoming almost universally recognized, some means of transporting urinary and other deposits, tumors, etc., over long distances, in the unaltered condition, has become a great desideratum. As a contribution towards this important object, I offer to the profession the subjoined method, originally contrived to meet the exigencies of a recent case in my own practice.

The clinical history in this particular instance, being accurately noted by the patient himself, a highly intelligent physician, gives such an exquisite picture of one form of the special renal malady in question, that I am confident most of my auditors will feel some interest in its relation, which is briefly as follows:—

About the 20th of August last, I received a letter from Dr. ——, residing in one of the trans-Mississippi States, informing me that he had forwarded to my address two specimens of deposit let fall from samples of his own urine, which he wished me to examine. In speaking of his condition, he remarked,—

"I am forty years of age, and for the last four years my health and strength have been steadily failing. From my normal weight of 165 pounds, I have declined gradually to 132, at the rate of about eight pounds per annum. My condition at first was attributed to malarial fever, but this cause has not involved the case for more than two years. My symptoms have, during this time, been as follows: great general debility, more or less dyspeptic symptoms, aggravation of rheumatic stiffness and soreness (not pain), from which I have suffered for years. A constant tendency to lose the erect position, and droop in the neck and shoulders. A gradual impairment of virility, amounting for the last six months almost to extinction. In fact, to sum up all in a word, general debility without apparent cause covers the case. I have run the gamut, under the ablest advice, of tonics, stimulants, and nutritious diet, and have taken a sea-voyage of three months' duration, with no appreciable benefit. A few months ago I accidentally discovered—what had never before been suspected—the presence in my urine of albumen in large amount. Its presence is persistent, and its quantity on the increase. The deposit after being precipitated, and allowed twelve hours to settle, just half fills the tube. I have never had any sign of dropsical effusion, but for the last year or more have suffered from periodical attacks of almost uncontrollable diarrhœa, developing themselves with much regularity about every two months, and lasting from three days to as many weeks. The amount of urine secreted is about thirty-two ounces for twenty-four hours, variable in color, but never turbid when fresh. I micturate a little oftener than when in health, always having to rise at least once during the night; urine much inclined to foam, sp. gr. normal (1021). Prof. ——, of Philadelphia, has pronounced my liver, spleen, and heart healthy, while my vital capacity as indicated by the spirometer is fifteen per cent. above par. . . . May I trespass upon your professional courtesy so far as to ask you to solve the problem, in which I am so much interested, by a microscopic examination? The presence of casts will of course demonstrate renal degeneration; but suppose no casts are found, what then? How in that case would my malady be termed? Certain it is I am suffering from something which, unarrested, must hurry me to a goal not dim or far distant. Please give me your views in reference to diagnosis, prognosis, and treatment. . . . Soliciting an early reply as the greatest favor that could be rendered to one in my present condition of suspense,—it is the *suspense alone* that tries me,—I subscribe myself, etc."

This letter—which, I should mention, Dr. —— with brave unselfishness, and in the spirit of a true philanthropist, has most generously given me permission to make free use of in preparing any paper upon the subject—was accompanied by a small box, enclosing the two samples of urinary deposit. Each specimen was contained in an ordinary two-drachm vial, stopped with a cork that previous to its insertion into the mouth of the bottle had been wrapped in a piece of thin India rubber, and then, being pressed in to the level of the lip, had been firmly tied down with another small circle of sheet caoutchouc. The ingenious precautions thus employed to prevent leakage were entirely successful, but the long journey of some twelve hundred miles, occupying more than a week of the hot weather with which we were visited during the past summer, had given time enough for complete decomposition to occur, and, although one of the specimens was prepared with a small portion of carbolic acid solution, entire putrefaction had taken place in both before their arrival. The vial which had been merely sealed up gave forth when uncorked a strongly ammoniacal odor, and its deposit was composed only of amorphous granular matter. The other specimen, to which carbolic acid had been added, contained an abundant white coagulum, without any tube-casts, epithelial cells, or leucocytes. Numerous mycelial threads of fungous vegetation presented themselves, and were probably capable of developing in the solution to which carbolic acid had been added, because that acid was deprived of its parasiticidal properties when it combined with the albumen of the urine.

On mentally reviewing the preservative agents at our disposal, and rejecting, of course, alcoholic and arsenical fluids, on account of their power of coagulating albuminous substances, it occurred to me that solution of acetate of potash, whose admirable properties as a preservative menstruum for microscopic objects formed the subject of one of my communications to this Section last year, would best serve our purpose; and I therefore wrote to my correspondent, informing him of the ill success of his first venture, and requesting him to prepare another specimen by filling a similar small vial with dry acetate of potash and then pouring in a fluid drachm of the sediment let fall from his morning urine after standing twelve hours in a cool place.

On the 12th of September I again received two samples, one of which had been mixed with the washings of a bottle that had formerly contained acetate of potash, and which comprised the doctor's entire stock of the salt; the other prepared with a small portion—about twenty drops—of alcohol. Both of these were worthless for microscopic examination; and I therefore procured a two-drachm vial of solid acetate of potash and forwarded it to my patient by return mail, requesting him as before to add to its contents a fluid drachm of his urinary deposit.

This last experiment in the preservation of a urinary sediment for transportation, the fifth of the series it completed, was entirely successful, the preparation reaching me about the 1st of October, not only in such a condition as to show well-defined hyaline, granular, and fatty epithelial casts of the uriniferous tubules in great abundance, but likewise embalming, so to speak, those pathognomonic signs of Bright's disease so perfectly that a drop of the fluid, which I have placed beneath one of the Academy's microscopes this evening, exhibits numerous tube-casts with admirable distinctness, even although more than six weeks have now elapsed since this identical sample which I here hold in my hand was prepared for examination, upwards of twelve hundred miles away.

During the past few years I have repeatedly felt the need of some method for preserving specimens of tumors and other pathological formations for microscopic investigation, which might prevent the alterations in the cellular elements which are so apt to occur with the media now in use, and also avoid the difficulty of sending fluids by mail, or the delay and expense attendant upon carriage by express. Since employing the plan described above, for insuring the portability of specimens of tube-casts, in spite of their exposure to either very high or very low climatic temperatures, I have made a few observations upon the effects of the acetate of potash solution upon morbid growths, and, as a result of my researches, recommend the following method.

Place a small fragment of any tumor or pathological structure, say a quarter to half an inch square and one-tenth of an inch thick, in a couple of drachms of saturated solution of acetate of potash, and allow it to fully imbibe the fluid by soaking therein for forty-eight hours. The solution referred to is best made by simply pouring half an ounce of rain-water upon one ounce of dry granular acetate of potash, in a clean bottle. When the tissue is thus freely saturated with this saline liquid, remove it by means of a pair of forceps, without much pressure, and insert it in a short piece of India rubber tubing, or wrap it up carefully in a number of folds of thin sheet rubber or of oiled silk, tying the whole firmly at the ends with strong thread. When thus prepared, specimens can be enclosed with a letter in an ordinary envelope, and sent long distances, doubtless thousands of miles, by mail, without danger, on the one hand, of decomposition, because of the preservative power of the potassic acetate, or, on the other, of desiccation, on account of its exceedingly deliquescent nature.

One very important advantage which this plan has over those in which alcohol or glycerin is employed as a preservative agent, is that the menstruum has little or no effect upon the oil-globules contained in cells. Hence by its aid we are enabled to recognize fatty degeneration in the cellular elements of a tumor, and easily to detect the same metamorphosis in the kidneys from minute oil-drops in the epithelium attached to tube-casts of Bright's disease, under circumstances where specimens preserved in glycerin or alcohol would afford a doubtful or wholly negative result.

Urinary deposits composed of oxalate of lime or of triple phosphate are not, according to my experience, readily preserved in solution of acetate of

potash, possibly on account of chemical decompositions which occur. When these crystalline bodies are met with, as is usually the case, in non-albuminous urine, they could probably be best retained in an unaltered state by adding from twenty to thirty per cent. of solution of carbolic acid to the renal secretion in which they are found.

No. 1620 Chestnut Street.

ANOMALOUS CASE OF PARALYSIS FOLLOWING DIPHTHERIA, AND SIMULATING LOCOMOTOR ATAXY.

BY WILLIAM C. KLOMAN, M.D.,

Baltimore, Md.

I WAS recently called to see S. R., a girl, aged five years and nine months, whom I attended during the latter part of September for diphtheria of the fauces. It proved to be a very mild case, from which she recovered without difficulty. Upon the establishment of convalescence, I ordered her a solution of the citrate of iron and quinine, which I directed should be taken for some weeks in cod-liver oil. The mother assured me that the remedies had been taken for at least ten days, when, the child appearing to have entirely recovered her strength and looks, she ceased giving them. Two days before I was again sent for, they had noticed an irregularity in her gait, and that her speech was indistinct.

Upon seeing the child, the first thing that struck me was her position,—she was standing at the time,—which was exactly that of one afflicted with Duchenne's paralysis. Her shoulders were thrown back, her abdomen projecting, and her spine incurved. Upon desiring her to walk, I found her gait to be staggering, like that of a drunken man, apparently showing great want of co-ordination, and it reminded me strongly of one suffering from locomotor ataxy. *There was no paralysis of any limb.* As far as I could judge, there was no loss of sensation, although this could not be made out with accuracy, because of the child's reticence and bashfulness. I tried to get her to place her feet close together and to close her eyes, in order to see if she could maintain the upright posture, but it was not satisfactory. She was unwilling to comply. Her speech, as much as I could get her to say, was thick and nasal, indicating faucial paralysis. She protruded her tongue without difficulty, which was somewhat coated. Her pupils were normal, acting under the stimulus of light, and her sight not affected. Her hearing was also good. At first I supposed I had a case of what the books call locomotor ataxy, which is said occasionally to follow diphtheria; and certainly many of the phenomena simulated that form of disease.

I mentioned the case to my friend Prof. F. T. Miles, of this city, and desired him to see the case with me. He pointed out phenomena in which there was a marked deviation from those attending locomotor ataxy. He was likewise struck with the child's position in the upright posture. He requested the child to place one of her feet upon a low stool, while she supported herself with one hand upon a table. She placed her foot upon the stool in a perfectly natural manner, and then did the same with the other. There was no incoordination of movement. She did not raise the foot too high and then bring it down with a slap upon the stool, and she raised it sufficiently high to avoid striking it against the edge of the stool and stumping her toe. Of course the conclusion was evident that this was not a case of locomotor ataxy. The child was directed to pick up a small object placed at her feet upon the floor, and after bending over to get hold of it she had considerable difficulty in again assuming the erect posture, and the conclusion was arrived at that there was paresis of some of the muscles of the spinal column, probably of the erector spinæ. Her mother also stated that if she was lying upon the floor she had great difficulty in getting up, unless there was some object near, as a table or chair, by which she could assist in raising herself, by using the muscles of the arm. Assuming, then, that there was paresis of some of the muscles of the spine, this would satisfactorily explain the peculiar phenomena of the case, viz., her peculiar position when erect, shoulders reared back, abdomen projecting, and buttocks protruded backwards; also the apparent want of co-ordination in her movements while walking; all of which are due to her efforts to preserve her equilibrium, in the absence of the firm column of support usually afforded by the spine. This child is rapidly improving under the use of strychniæ gr. $\frac{1}{32}$ with 2 grs. citr. iron and quinine, and a teaspoonful of cod-liver oil three times daily, together with stimulating frictions to the spine.

TRANSLATIONS.

OUTLINES OF A SYSTEM OF PHYSICAL OTIATRICS.

From the German of Dr. Erhard, Instructor in the University of Berlin,

BY C. H. BURNETT, M.D.

AFTER investigating the hearing-power in all persons hard of hearing *per ossa et per cavitatem*, respecting irregular as well as periodical vibrations, I have come to the following conclusions:

I.—Respecting those hard of hearing who perceive sounds and musical notes normally *per ossa*. These must possess normal fenestræ, labyrinths, and labyrinth-contents, normal innervation, normal ventilation by the Eustachian tube, and normal pressure in the labyrinth. Among these are—1. Such as perceive ordinary noises imperfectly *per cavitatem*, but possess normal perception for music, and good hearing for speech. These cases are rare. The conductor, in an isolated condition, is still elastic, but on account of the increase in its bulk has become relatively impeded. In such cases the membrana tympani is seen to be loaded with calcareous deposits.

2. Such as hear noises normally *per cavitatem*, but hear musical tones imperfectly, and speech, relatively, badly. In these cases the conductor, in its isolated con-

dition, possesses too little resonance, for the membranæ tympani often show great defects, other things being normal: these also are very rare cases.

3. Those who hear *per cavitatem* neither noises nor musical tones normally. Under the latter head we may, by ocular inspection, recognize two distinct groups.—*a*. Those cases in which the membranæ tympani neither are defective nor have been, and in which otorrhœa is not present. In these the membranes are retracted, and the conductor, *i.e.* membrane and ossicula, in consequence of deposits, have not the proper degree of freedom in motion, in fact are impeded, yet without producing an interference in the resonance of the fluid in the labyrinth by pressure,—a fortunate as well as rare issue of these anomalies; or the conductor may still be in a condition of cellular integrity, but improperly situated, by means of the collapsed and retracted membrana tympani, which forces the head of the malleus and body of the incus upward against the roof of the tympanum, thus destroying both their normal isolation and resonance. In all of these last-mentioned cases the important object is to place the ossicula in a normal position. This can sometimes be accomplished, even in chronic cases, by means of a powerful introduction of air into the tympanum, or by means of a fortunate incision or perforation of the membrana tympani; but for one successful incision we may make one hundred fruitless ones. *b*. The membranæ tympani may be or may have been defective, and otorrhœa may have been or still is present. Generally the hearing is imperfect because the ossicula are imperfectly supported, or, as is more likely to be the case, they are in a disconnected state. Such cases are often those which furnish the most brilliant results of physical treatment. In these cases, if we insert into the meatus a piece of moist cotton, and allow it to press upon the remnants of the membrane, so as to exert pressure upon the ossicula, we may overcome the imperfect connection of the bones, *i.e.* their dislocation, and render the perception of ordinary sounds normal, although musical tones are not heard any better by this procedure in such cases. If now we take a small stick, —say a match,—and fasten to one end of it a membrane with a superficies of one square inch, or a card, and place the free end upon the cotton, or, in other words, lengthen the reconstructed conductor, uniting it with a freely moving and isolated membrane, we shall at once find that musical tones are normally heard.

II.—Those hard of hearing who perceive *per ossa* musical tones correctly, yet hear ordinary sounds imperfectly. These must possess, just as those in Class I., normal fenestræ in the labyrinth and normal ventilation by the Eustachian tube. If the affection is confined to one side, they hear the fork, when placed upon the forehead, best on the affected side, and the watch, similarly placed, only on the healthy side.

This kind of affection on both sides may be attended by certain exceptions, such as—1. Those who perceive musical notes *per cavitatem* absolutely normally, and also noises relatively normally; or we may say absolutely normally in comparison to their deafness *per ossa*. In such cases the entire membrana tympani must be intact, and therefore, in these cases, *ceteris normalibus*, the cause of the disturbance in function must be an insufficient innervation of the ramus vestibuli, or a loss of the acoustic hairs (Hörhärchen) in the vestibule, a result of a former morbid pressure exercised upon the labyrinth *per cavitatem*.

The first of these causes is always ambilateral and congenital; sometimes, though very rarely, it may be unilateral, and then it is the result of a powerful concussion, or of a long-continued closure of the Eustachian tube and absorption of the air in the tympanum on the affected side. In the congenital cases the patients are affected with tinnitus. These come to our notice only casually. Not so the cases of induced trouble of this kind. The former understand speech very well, but unconsciously fix their eyes upon the speaker. A distinguished general, who supposed he possessed normal hearing, asked me to see a friend who presented the acoustic conditions of those described in I., 3 *a*. During the consultation the general was very anxious to test his own hearing, and upon applying the tests it was found, to his great astonishment, that he was unable to hear the watch *per ossa*, but heard both the tuning-fork and the watch normally *per cavitatem*, the latter absolutely normally in comparison to his inability to hear it *per ossa*. He was unable to hear *per ossa* a "repeater," but heard easily an ordinary ticking watch held close before the ear. His deaf friend heard all noises better than the general, but the latter perceived all musical notes and sounds much better than the former.

2. We often find this condition of hearing during a painful unilateral affection of the external auditory meatus,—viz., furuncle. In such cases I believe that the infiltration of the cellular tissue exercises a pressure upon the ultimate parts of the organ of hearing—even upon the acoustic hairs of the vestibule. When the infiltration disappears, the pressure is diminished, and the hearing for the watch *per ossa* is usually, though not always, restored. Also in cases where cerumen touches the membrana tympani, the watch is not heard *per ossa* until the removal of the inspissated mass. Formerly I regarded these symptoms in cases of inflammation in the external auditory meatus as those of a participation of the labyrinth in the inflammatory process of the external ear,—assuredly with error; for why should the vestibule be a participant in the inflammation, and not the much more vascular cochlea?

3. In cases of chronic progressive deafness we often meet the following conditions: normal hearing for the tuning-fork *per ossa*, yet very abnormal *per cavitatem*, —in fact, they hear the fork *per ossa* after it ceases to be heard *per cavitatem*. They also show a progressive abatement in the perceptive power for the watch *per ossa et per cavitatem*.

In these cases the cause is found to be the increasing amount of pathological deposits in the conductor, and an increasing obstruction to its proper isolation in the cavity of the tympanum; increasing anchylosis of the base of the stapes, with, of course, an increased pressure upon the *crista acustica*, etc., although the membrane of the round window may remain perfectly intact. These are the individuals who hear better with the ear-trumpet between their teeth than with it in the meatus auditorius externus, for they possess only a normal cochlea and its appurtenances.

(To be continued.)

Uræmic Encephalopathia.—This is the designation given by M. J. Parrot, in a series of elaborate papers published in the *Archives Générales*, to that disease generally known by the profession as tetanus of infants, or infantile trismus. The author asserts that the resemblance to true tetanus is slight and only apparent; that the disease is one of the forms of eclampsia; and that, so far as the causes and the symptoms are concerned, it is directly connected with *uræmic encephalopathia;* in that variety where tonic convulsions predominate, is absolutely the same.

Dr. Otterson succeeds the late Dr. Cochran as Health Officer of Brooklyn, L. I.

PHILADELPHIA

MEDICAL TIMES.

A WEEKLY JOURNAL OF

MEDICAL AND SURGICAL SCIENCE.

The Philadelphia Medical Times is an independent journal, devoted to no ends or interests whatever but those common to all who cultivate the science of medicine. Its columns are open to all those who wish to express their views on any subject coming within its legitimate sphere.

We invite contributions, reports of cases, notes and queries, medical news, and whatever may tend to increase the value of our pages.

All communications must bear the name of the sender (whether the name is to be published or not), and should be addressed to Editor Philadelphia Medical Times, care of the Publishers.

PUBLISHED EVERY SATURDAY BY

J. B. LIPPINCOTT & CO.,

715 and 717 Market St., Philadelphia, and 25 Bond St., New York.

SATURDAY, DECEMBER 21, 1872.

EDITORIAL.

BLACK LISTS.

FEW physicians practise their profession long without finding out that earning money is one thing, and collecting it another. There is a certain class in the community who seem to prey upon recent graduates,—sending for them, flattering them, relating how Dr. So-and-so said, "Never allow any one, my dear madam, to give you morphia in any form," or how Dr. Something-else said, "The most remarkable case I ever saw,"—who take many airs of patronage upon themselves, but who afterwards ignore the bills sent to them, and perhaps grievously malign the aforesaid young men for ever after. Others there are who take less trouble; who, when they want medical attendance, send for it, knowing that they cannot or will not pay for it, and simply expecting to change their doctor every time they need one. Still another class, unfortunate but well intentioned, get from year to year deeper into debt to physicians, who, one after another, find their unrequited labors too great a burden.

To remedy these evils, it has been from time to time proposed, and the experiment tried, that "black lists" should be made out of those who do not pay their doctors, and that attendance should be refused to such as figure in these gloomy catalogues. But there are two elements wanting in all the attempts of this kind that have been made within our knowledge: first, that the lists should contain the names of those only who could pay if they would, and, secondly, that the agreement to withhold medical service should be general.

We are fain to believe that most professional men are too generous to make a personal matter of their desertion by patients who have paid their dues, and therefore that it would only seldom happen that a name would be inserted in the black list on this ground. And no one knows better than a struggling physician how urgent and imperative are the demands of the butcher and the baker and the landlord, of the tailor and the bootmaker. No one ought to know better how hard it is to meet every claim, and how strong the temptation is to postpone those which seem least pressing. No one, therefore, can know better how difficult it is to tell who the real delinquents, the doctor-swindlers, are. If we had lists of these, and these only, it would be well.

Then, if the whole profession were a unit in declining to submit to any further imposition on the part of these non-paying patrons, there would be some prospect of the nuisance being abated. But, as it is, only a very few are in possession of the lists, such as they are; and of those few we doubt whether one in ten, being sent for to a new patient, looks for the name among the proscribed, or, finding it, would resolutely refuse to render the required service. Humanity, indeed, would be thought to be outraged, if a life should be lost because the patient had employed other doctors without paying them.

We do not believe all the "black lists" in the world would do as much good as the establishment of the custom of sending out monthly bills to our patients, and of demanding prompt payment. And if it were recognized as common law that no patient with an unpaid doctor's bill could claim further service from him, or from any other doctor who chose to decline it, and that the profession owed mutual support to one another in this respect, we believe that the need of black lists would become less and less, until—perhaps with the beginning of the millennium—it would cease altogether, and medical attendance be as much "value received" as merchandise now is.

THE WARD'S ISLAND SCANDAL.

IN our issue of December 7 we noted editorially the fact of the summary dismissal of Dr. Echeverria from the post of Resident Physician to the Insane Hospital at Ward's Island, where he had refused to abet or sanction abuses which were at least winked at by the Commissioners of Public Charities and Correction. The reports, in the daily papers of New York, of the coroner's inquests in the cases of some of the

alleged victims of maltreatment in the Asylum, and letters published by Dr. Echeverria, have satisfied us that the affairs of the institution were certainly very bad.

We refer to the matter again, not perhaps for the last time,—for it is to be hoped that a searching investigation will be made into the conduct of the attendants, the mode of employing them, and the degree to which the commissioners were collectively and severally responsible for the neglect and cruelty exercised towards those who were placed in their charge,—but to speak of the professional aspect of the trouble. Here is a physician who, for trying to do his duty, is abruptly and discourteously turned out of his situation in a public institution. Who is to take his place? It will not do for the field to be abandoned to any more willing tool of the corrupt authorities, and yet it is hardly to be supposed that other men of good character and honorable standing will readily or of choice assume an office vacated in such a way. Under the circumstances, however, we believe that the best interests of all concerned would be promoted by a successor of the latter kind. Dr. Echeverria would assuredly find his most effectual vindication in the testimony of one who should take things as he left them. The patients would of course be equally certain to benefit by the proper care they would thus receive. And the public would have the advantage of knowing far better how things really had been going on, and how trustworthy or untrustworthy their commissioners had proved.

We make these remarks, not knowing who has been appointed to the position, but well aware that the profession in New York affords many men who, unless deterred from assuming the duty by the ill treatment of their colleague, would be found equally incorruptible; and hoping that one of these may have been selected to succeed him.

THE NEW HOSPITAL OF THE UNIVERSITY OF PENNSYLVANIA.

WE are glad to be able to report that the important movement for the establishment of a General Hospital in connection with the University of Pennsylvania, which has been noticed several times before in these columns, is advancing very satisfactorily. The plans have been, during the past summer, under the consideration of a committee of gentlemen of experience, and it is believed that, as finally adopted, they represent a combination of advantages unsurpassed by any modern hospital. The proposed building will consist of a large central structure containing the offices of administration and amphitheatre for clinical lectures; the pavilions for the accommodation of patients will be connected with this by corridors. Each of the pavilions is designed to accommodate about ninety patients, and the plan is so arranged as to admit of the successive addition of pavilions on either side of the central building, until the entire completed structure will present a front of over six hundred feet, and be able to accommodate between five hundred and six hundred patients. Unfortunately, this is merely the prospective future of the Institution, and we fear it may be years before it is fully realized. The present intention is to erect only the central building and two pavilions, which will accommodate one hundred and seventy-five patients. Work has been actively begun upon the foundation-walls of these, and it is expected that the first wards will be opened before the end of 1873. The hospital, in general appearance, is to be in harmony with the building of the Academic Department, and will stand opposite to the latter on the south side of Spruce Street. The preparation of the plans and the supervision of the building have been intrusted to the architect of the University, Mr. T. W. Richards,—whose success with the Academic Department leaves no room for doubt that the present work will be most efficiently accomplished.

CORRESPONDENCE.

To the Editor of the Philadelphia Medical Times:

BY a typographical error occurring in the report of the Pathological Society, published in the December 7th issue of your journal, in speaking of the cartilaginous tumors of the larynx and trachea, we are made to designate them as "*enchondroma*," instead of *ecchondroma*. It is maintained by eminent authorities that the term enchondroma should be strictly limited to heterologous growths which do not arise from pre-existing cartilage, but from some non-cartilaginous matrix; ecchondroma being reserved for such as spring from cartilage. Accepting this view, cartilaginous tumors of the respiratory tract should be designated as ecchondroma.

Operation for Extra-uterine Pregnancy.—The *Lancet* of Nov. 9 says, "A case of extra-uterine gestation was operated on last Saturday by Mr. Lawson Tait, at the Birmingham Hospital for Women. The abdominal section was made, and a dead child removed. The case is doing well."

PROCEEDINGS OF SOCIETIES.

BIOLOGICAL AND MICROSCOPICAL SECTION OF THE ACADEMY OF NATURAL SCIENCES.

November 4, 1872.

Director W. S. W. Ruschenberger, M.D., in the chair.

Dr. JOSEPH G. RICHARDSON read a paper entitled "A New Method for Preserving Tumors and Certain Urinary Deposits during Transportation," in which he urged the employment of an acetate of potash solution for this purpose, and detailed a case illustrating the advantages to be derived from its use. (See p. 181 of the current number of the *Philadelphia Medical Times*.)

Dr. James Tyson remarked that he had several specimens of urinary deposits, sent from distant points, indeed as far as the Gulf States, merely sealed up, which had arrived in good condition; but thought that in warm weather this proposed plan might be very useful. In regard to morbid growths his experience was that such as had been put up for transportation in glycerin had done better than those preserved in alcohol, although good sections might occasionally be cut from the centre of a large mass of tumor-substance if not very long immersed in the latter medium. He had found nothing in the way of a preservative liquid so satisfactory as the saturated solution of the acetate of potash, whose precise qualities in this respect he was now testing in his own laboratory, and proposed to report to the Section at some future day.

Dr. Hare observed, in reply to a question, that he did not think any chemical decomposition would occur between oxalate of lime crystals and acetate of potash, and was inclined to attribute the disappearance of the octahedra mentioned by Dr. Richardson to a process of simple solution in the liquid.

Dr. Tyson stated that he had mounted oxalate of lime in lime-water and in various other fluid media, entirely without success, although he had found that the crystals keep well for a considerable time when imbedded in balsam.

Dr. Ruschenberger remarked that he had seen the octahedra gradually disintegrate even when mounted in Canada balsam.

Dr. Hare mentioned that in the course of some experiments on the production of large octahedra of oxalate of lime, he had observed the crystals grow constantly larger on several successive days in urine charged with the salt, after eating food containing the oxalates, such as rhubarb-plant or tomatoes.

Dr. Tyson added that he had even mounted those crystals in urine from which they had been deposited, and yet in a short time they disappeared.

Dr. Hare inquired of Dr. Tyson whether he had ever known the tube-casts of Bright's disease to be preserved in the urine from which they had been let fall, for so prolonged a period as those in the specimen upon the table.

Dr. Tyson stated that samples of urine forwarded to him from considerable distances had almost always arrived in good condition, but it had so happened that they were transported during cold, or moderately cool, weather.

Dr. Richardson observed that, in his experience, during the hot season, the tube-casts of Bright's disease commenced to undergo disintegration on the third or fourth day, and very soon afterwards became unrecognizable, being obscured by myriads of bacteria, which seemed to feed upon, or at to least develop at the expense of, the nitrogenous matter in the casts. In marked contrast to this rapid disintegration was the uninjured condition of the casts beneath the microscope on the table, although they had now been preserved for six weeks, including part of the warm weather in September last.

Dr. Tyson inquired whether the early destruction of casts met with by Dr. Richardson was not found to occur in specimens exposed to the air by standing uncovered in a conical glass.

Dr. Richardson replied that he had noticed the changes alluded to, both in unprotected samples and (although somewhat less promptly) in those contained in tightly-corked bottles, but, like his friend Dr. Tyson, had frequently seen casts preserved unaltered for several days in cool weather. He also called attention to the fact that, in cases where specimens were exposed *in transitu* to extremely low temperatures, their immersion in this solution of acetate of potash would enable them to escape without injury from freezing.

Dr. Tyson remarked that since the discussion had assumed so decided a urinological character it might interest the members to hear certain points in the history of two cases of Bright's disease which he had recently met in the Philadelphia Hospital, which bear on this subject, and which illustrate some of the difficulties in an accurate diagnosis of the different forms of this malady.

One was the case of a boy in the wards of his friend Dr. Pepper, with a scrofulous history, and the subject of phthisis. He was passing, before death, 130 ounces of pale urine, which contained numerous hyaline casts, all pointing to the existence of an albuminoid kidney. From the mode of accession of the attack, however, Dr. Pepper was led to suspect a *large white kidney*. This, on post-mortem examination, proved to be correct. But further examination also furnished the most beautiful albuminoid reaction of the Malpighian bodies of the cortex, and straight vessels of the cones. Thus was presented an instance of a mixed form of Bright's disease, the albuminoid and smooth white organ combined.

The second was a case which occurred in Dr. Tyson's own wards, in a woman 45 years old, who entered the house with partial suppression of urine, passing but two to four ounces in the twenty-four hours, of a smoky-hued fluid, which contained seven-eighths of its bulk of albumen, blood, and epithelial casts, commingled with granular and hyaline casts. A volumetric analysis exhibited a secretion of but 1.48 grammes of urea in the twenty-four hours. These are all the conditions of a case of acute inflammation of the kidneys. The history of the case previous to admission, however, led Dr. Tyson to diagnosticate granular kidneys, and to believe the symptoms present during the entire period of her residence in the house to be the results of an acute exacerbation. Such proved to be the case on post-mortem examination. The kidneys were perfect examples of the granular contracted organs.

REVIEWS AND BOOK NOTICES.

The Pathology, Diagnosis, and Treatment of Diseases of Women. By Graily Hewitt, M.D. Philadelphia, Lindsay & Blakiston, 1872. Second American, from the Third London Edition.

Dr. Hewitt's book on the diseases of women was so thoroughly reviewed and criticised by the various journals which greeted the appearance of the first and second editions, that any further extended notice would be superfluous, were it not that the third edition has been so modified, in fact so completely re-

written, that we are unconsciously reminded of the bright-eyed Fräulein at Prague to whose lot it had fallen to exhibit the horse which the ill-starred Wallenstein had ridden at the battle of Lützen: "The head, neck, part of the body, and the legs, sir, have been restored, but all the rest is the original animal." The unfortunate arrangement of the first edition greatly impaired its usefulness; its object was to facilitate diagnosis, and, in order to do this, "symptoms, not pathology, were made the basis of arrangement,"—so that, as in a homœopathic vade-mecum, a certain combination or group of symptoms could not but suggest the diagnosis and treatment, utterly ignoring the various morbid conditions which could alike give rise to the same clinical phenomena. Like a house without foundations, such a structure could not possess either strength or durability, and in the second edition a new element was introduced, viz., Pathology,—which was dexterously inserted under the old, as builders by means of screws and rollers lift up an old tenement and supply the wanted story or foundation. But the result was not successful; pathology and diagnosis were united, it is true, but they were only chained together, not organically one, and hence the endless repetitions irritated the reader and prevented the work from ever becoming a generally popular one. But now at last, tired of this patchwork, Dr. Hewitt has abandoned the attempt, and has erected a new edifice, of which pathology is the corner-stone; but, alas! this tearing down of the old idol was only to erect another and a greater one. In the first edition we found an excellent account of the diseases of the ovaries, those tiny organs, which, hidden away in the deep recesses of the pelvis, exert so powerful an influence on the entire existence of the woman, functional or organic diseases of which must be productive of such serious consequences; but in the present edition the symptoms referable to ovarian irritation are deprived of their usual significance, attributed to uterine displacement, and the statement which Dr. Hewitt himself makes is unquestionably true, viz., "that many cases which he has put down as diseases of the uterus would be claimed by some eminent authorities as diseases of the ovaries."

But what is this new mechanical system of uterine pathology, the importance of which seemed so great to our author as to lead him to revolutionize his own labors? It may be that, like the dishes in a French bill of fare, we fail to recognize an old friend by its new name.

In the first chapter the author gives a résumé of the cases which have come under his care in the University College Hospital, in justification of his statement that he is no longer dealing with "speculative theories," but eternal truths, for his ideas "have been in conformity with daily observation" at a bi-weekly clinic during *all* this time. Dr. Holmes tells us that he once inhaled ether in the hopes of being able to study psychologically its effects on the mind. While recovering from the stupefaction produced by the drug, it suddenly seemed as though the great secret of existence was revealed to him. With tottering steps he approached his study-table, and by a mighty effort wrote down the mystic words. When he finally became conscious, still impressed with the importance of his great mission, he opened the paper and read this revealed truth: "A strong smell of turpentine pervades the room."

On the second page of the new system we find this axiom,—"Patients suffering from symptoms referable to the uterus are almost universally *affected with flexion* or alterations in the shape of the uterus of an easily recognized character." Dr. Hewitt will not argue the question, whether or not these women who to-day are "affected with flexion" were previously affected with an inflammation of the organ, although his own views on the subject are shown in the following sentence: "logically and practically there are good reasons for placing flexions first in the order of sequence." But this is not the important issue to-day: time was when under the leadership of Kiwisch, Scanzoni, Martin, Simpson, and Hodge, the battle would have raged fiercely around this point, but now Dr. Hewitt directs our attention to the fact that, "putting aside the cases of cancer, fibroids, and pelvic cellulitis, the residue of cases of the entire number seen in the University clinic where the diagnosis was confirmed by an examination, in which no flexion was found, was *very trifling indeed*." And, indeed, as an eye-witness, we too will gladly bear testimony that a woman entering the consulting-room "presenting uterine symptoms" was indeed an anomaly if she did not suffer from anteflexion of the uterus to such a degree as to demand imperatively the use of Dr. Hewitt's "cradle-pessary;" and yet how significant the fact that within five minutes' walk the surgeons of the "Soho Square Hospital for Women" attended every morning from fifty to one hundred patients, and the use of a pessary was a rare exception, and that, too, when one of the surgeons in attendance has identified his name with one of the best intra-uterine pessaries yet suggested. Yet in this hospital, as in the other, under judicious general treatment, and the recognition of other more comprehensive causes than mere displacement in the production of uterine diseases, the results were most satisfactory. Crede's paper on "The Normal Position of the Uterus"—so often referred to in this journal—makes a far better exhibit with regard to the frequency of anteflexion than these selected cases of Dr. Hewitt's; but after a critical review of the statistical results, which is a model for vigorous exclusion of extraneous matter and philosophical deduction, what is the result reached? "That the normal position of the uterus involves a greater or less degree of anteflexion; that the pathological conditions which arise coincidently are the important element, while the displacement is of no consequence, and hence that the mechanical intra-uterine treatment with sounds and pessaries, which is at least superfluous, and in many cases dangerous, must be more restricted in its field of application." The extreme degrees of anteflexion of the uterus, such as sometimes occur, and which always constitute an exceedingly intractable condition, as well as cases of retroflexion, which is always a pathological condition, producing in most cases real and serious trouble, are not, of course, included in this category.

Fortunately, the treatment of flexions—the principal disease to which the generative organs in the woman are liable—is such a one as can be easily followed by the many victims of this Protean malady. Rest, absolute rest, is the essential element of success. In cases of retroflexion, "a position upon the face is secured by a kind of inclined plane of pillows, by which means a very comfortable position is secured," which must be maintained, "in cases where there is much irritation about the uterus, for some weeks." Ennui is prevented, however, by the introduction of the sound once in two or three days, and by the continuous use of the ring or "cradle-pessary," care being taken that "the cervix is not caught between the two projecting arms of the instrument," which accident, we are assured, is now guarded against by the addition of a cross-bar.

The value of Dr. Hewitt's book in other points is well known. Its great fault, which has prevented its adoption as a general text-book, was its arrangement, which has now been so modified that it is beyond criticism. It is its very excellence which makes us unwilling to pass over in silence the great danger, which is imminent, of its usefulness being impaired by the in-

troduction of the so-called mechanical system of uterine pathology, which at present so completely occupies the author's attention. Yet, as Scaliger wrote, "*ars etiam maledicendi;*" and we trust that we have not overstepped the limits of criticism in protesting against the undeserved prominence which displacements of the uterus occupy in this work.

The Physician's Visiting-List for 1873. Twenty-second year of its publication. Philadelphia, Lindsay & Blakiston.

Probably very few of our readers will need to have their attention called to this indispensable little volume, —the best of its kind within our knowledge. Convenient in size and arrangement, it has acquired a well-deserved popularity, attested by the yearly increasing demand for it.

BOOKS AND PAMPHLETS RECEIVED.

A Manual of Histology. By Prof. S. Stricker, of Vienna, Austria. In co-operation with Th. Meynert, F. von Recklinghausen, Max Schultze, W. Waldeyer, and others. Translated by Henry Power, of London, James J. Putnam, and J. Orne Green, of Boston, and others. American Translation edited by Albert H. Buck. With 431 Illustrations. 8vo, pp. 1106. New York, William Wood & Co., 1872.

Obstetric Aphorisms: For the Use of Students commencing Midwifery Practice. By Joseph Griffiths Swayne, M.D., etc. Second American, from the Fifth revised English Edition, with Additions. By Edward R. Hutchins, M.D. 12mo, pp. 189. Philadelphia, Henry C. Lea, 1872.

A Discourse commemorative of the Life and Character of Samuel Jackson, M.D., late Professor of the Institutes of Medicine in the University of Pennsylvania. By Joseph Carson, M.D., Professor of Materia Medica, etc. 8vo, pp. 32. Philadelphia, 1872.

Report on Climatology and Epidemics of Pennsylvania for 1871, particularly the Epidemic History of Smallpox in Philadelphia. By W. L. Wells, M.D. From the Transactions of the American Medical Association. 8vo, pp. 26. Philadelphia, 1872.

A System of Oral Surgery. Being a Consideration of the Diseases and Surgery of the Mouth, Jaws, and Associate Parts. By James E. Garretson, M.D., etc. 8vo, pp. 1091. Philadelphia, J. B. Lippincott & Co., 1872.

A Hand-book of Post-Mortem Examinations, and of Morbid Anatomy. By Francis Delafield, M.D., Curator to Bellevue Hospital, etc. 8vo, pp. 376. New York, William Wood & Co., 1872.

In Memoriam. Proceedings of the Medical Society of the District of Columbia, June 7, 1872, in reference to the Death of George Richards Miller, M.D.

GLEANINGS FROM OUR EXCHANGES.

Origin of Pus-Corpuscles.—Dr. R. H. Fitz (*Boston Med. and Surg. Journal*, October 17) says that F. A. Hoffmann (*Virch. Arch.*, vol. liv., 4 Heft), with P. Langerhans, has already shown that some time after the injection of cinnabar into the blood-vessels, grains of the same could be found in the fixed cells of the connective tissue, and that whenever an irritation had occurred, the accumulation of pigment in these cells became so great that one could recognize the place with the naked eye, by the red color.

Hoffmann (in the present article) states that wounds were produced and afterwards cauterized, or dilute acetic acid was injected; twenty-two to twenty-four hours after inflammation was thus excited, injections of cinnabar were made.

The pus from the wounded surface contained no cinnabar, yet the tissues from which the pus came contained cells in which were numerous particles of cinnabar; these cells corresponded completely with the so-called fixed connective-tissue cells. The pigment was also found in clumps, imbedded in a dense fibrous stratum; tearing apart these clumps, there were found grains of cinnabar, free or sticking to the tissue-fibres, cells containing pigment, and débris of cells. These were, doubtless, the remains of encapsuled abscesses. Apart from them, free cinnabar granules were not found in the connective tissue. Hoffmann infers that the fixed cells take no part in the production of pus, but remain wholly passive. Were they destroyed, the cinnabar must be set free after seven to nine days' suppuration, and be found as such, or taken up by the wandering cells. Were they active, it would be probable that cinnabar would appear in the pus, especially as the pigment was found in large amounts in the vicinity of the suppurating surface. Hoffmann had previously shown that cell-proliferation in the extirpated cornea occurs, and, from negative testimony, he inferred that the increase proceeded from the fixed corneal corpuscles.

Stricker has found that the wandering cells are capable of division after leaving the vessels, so that the previous inference cannot be regarded as doubtful.

In conclusion, he states, "Up to the present time, any other source for pus-corpuscles than the blood-vessels has not been proven nor placed upon a scientific basis."

Prof. Schiff, in a lecture before the Academy of Sciences at Florence (*Berl. Klin. Woch.*, 1872, No. 14), asserts that in extensive suppuration the white blood-corpuscles might be replaced in a manner suggested by the experiment of enucleation of the spleen. When this operation is performed on dogs, these corpuscles increase if the animal remains healthy; much more so if peritonitis follows the operation. He asserts that the increase of these depends upon an irritation of the inner coat of the blood-vessels; the more extensive this is, the greater the increase. One can, therefore, regard these as the product or transformation of the epithelial cells clothing the intima. This condition might be called a catarrh of the same.

Post-Mortem Delivery (*Dublin Journal of Medical Science*, September, 1872).—At a meeting of the Dublin Obstetrical Society, May 18, 1872, Dr. Darby detailed the following case:—

"Anna Maria Doyle, a robust woman, aged 24 years, the mother of one child, and in the sixth or seventh month of her second pregnancy, was admitted to the Rathdown Fever Hospital in typhus fever, on the 2d of March, 1871. Was seized with violent epistaxis shortly after midnight on the morning of the 6th. I was at her bedside by five o'clock A.M., and found she had been dead for ten or fifteen minutes. The left shoulder, arm, and side were swollen, black, and covered with large bullæ containing yellowish serum; the smell from the body was unbearable, and I ordered the body to be removed from the ward (in which there were six or seven patients) to an empty room on the same floor. In consequence of her advanced pregnancy when admitted, I desired the nurse to be on the watch for uterine symptoms. None such presented up to the time of her death, nor, after the removal of the body to the vacant room, when it became the duty of the nurse to

make a special examination, was there any discharge or other circumstance to attract attention. In six or seven hours afterwards the nurse had occasion again to enter the room; she then observed that a putrid fœtus of about the sixth month, with the secundines, had, subsequently to her previous visit, escaped from the dead body. All this was reported to me. I saw the fœtus, and have no reason to doubt the accuracy of the nurse's account of the circumstances connected with this rare and interesting case. A question as to whether post-mortem parturition results from vital organic action of the uterus after the death of the individual, or whether rigor mortis may be sufficient to expel a fœtus from an already dead body, or whether the rapid generation of gases therefrom may not, with more probability, be the producing cause of the phenomenon, is a matter of grave consideration both in its physiological and medico-legal aspects; and, while I abstain for the present from offering any decided opinion on these points, I hope some member present may be induced to initiate a discussion which may let in some light upon a subject which requires further elucidation."

The Double Murmur of Duroziez in the Arteria Cruralis, and its Significance in the Diagnosis of Insufficiency of the Aortic Valves (Hoffmann, assistant to Von Ziemssen in Erlangen: *Berliner Klin. Wochenschr.*, Sept. 2, 1872).—Under normal circumstances, a double murmur may always be heard in the large arteries lying near the heart, the first part of which, occurring at the moment of diastole, is caused by the sudden and forcible rushing of the torrent of blood into the elastic vessels; while the second part of the double murmur is systolic, and is caused by the closure of the aortic valves. In the distant arteries, however, as in the *cruralis*, only the first part of the murmur is heard normally; whereas the second part is never heard in the healthy condition.

In cases of aortic insufficiency, the second tone may also be detected, even in the most distant vessels, as described by Duroziez, who failed, however, to give any explanation of the phenomenon.

Traube, Friederich, and Riegel, among German writers, have alluded to this fact, but only the latter has endeavored to account for it.

His views have obtained a complete introduction into German hospitals, and Dr. Hoffmann relates a case under the care of Professor von Ziemssen, which illustrated during life all the phenomena of aortic insufficiency, with the so-called "double murmur" of Duroziez in the crural artery, and, upon post-mortem examination, all the signs noted during life were substantiated by the pathological changes in the heart.

In conclusion, Dr. H. says, "The clinical worth of the double murmur may be said to consist in the indication of the *presence of extensive insufficiency of the aortic valves without stenosis; extensive hypertrophy of the left ventricle, notwithstanding which, there is no degeneration of the muscular substance of the organ; and the presence of normally elastic, non-sclerosed arterial walls; all of which conditions are necessary*, according to Riegel, for the production of the double murmur of Duroziez in the crural artery."

Resection of the Superior Maxilla on account of Cylindroma, with Preliminary Tracheotomy and Tamponnement of the Larynx (reported by Heiberg, from the clinic of Schönborn, of Königsberg, Prussia: *Berlin. Klin. Wochenschr.*, No. 36, 1872).—The operation was performed upon a laborer thirty-six years old. Swelling of the left cheek had been noticed for four years and nine months previous. There had never been any pain, the health has always remained perfect, and the man passed through the recent Franco-Prussian campaign as a private. The tumor was everywhere adherent to the bone,—had the consistence of cartilage, and fluctuated at certain points. His speech was slightly impeded, but perfectly intelligible. The act of swallowing was somewhat inconvenient.

After the patient had been placed under the influence of chloroform, in the usual way, tracheotomy was performed; a stout tampon, fastened to a string, was passed through the wound upwards against the under surface of the glottis; a canule was introduced, and through this the anæsthesia was kept up. During the operation for exsection of the tumor, despite the tampon already alluded to, blood was discovered trickling into the trachea, and a second tampon of cotton was pushed backwards behind the tongue, and thus the trachea was tamponed from above. During these manipulations around the epiglottis and trachea, the administration of chloroform was continued through the canule, and the patient breathed as "quietly as an infant." The incisions through the integument healed by first intention. In twenty-four hours the canule was removed from the tracheal wound, and on the nineteenth day after the operation the patient was discharged cured.

Apomorphine as an Emetic (M. Loeb, of Worms: *Berliner Klin. Wochenschr.*, No. 33, 1872).—The investigations of Siebert, Riegel, and Boehm, concerning the nature of this drug as an emetic, induced Loeb to try its effects in the case of a young man who had accidentally swallowed a large draught of alcoholic solution of oil of bitter almonds. The author says, "I was called to see the patient half an hour after the accident, and decided that an immediate emetic must be given. I therefore injected into the region of the stomach 0.008 of a fresh solution of apomorphine. In eight minutes, after repeated gapings on the part of the patient, copious emesis of a mass smelling strongly of hydrocyanic acid occurred. This recurred in five minutes. Then the patient recovered rapidly."

The success of this treatment is ascribed to the promptness of its action.

As a rule, no more than 0.008 of a solution of apomorphine, made in the strength of 0.12 : 4.0, is to be administered. This usually produces in adults two attacks of emesis. In a child thirteen months old, to whom the author gave 0.002 of a solution of this drug, alarming symptoms followed the first attack of vomiting.

(The above report is literally translated; the precise quantities used are not given, but probably 0.008 of a cubic metre, = 8 cubic millimetres, or a few minims, is meant.)

Electricity in Basedow's Disease (M. Meyer: *Berliner Klin. Wochenschr.*, No. 39, 1872).—Four cases are reported in this article by the author. In conclusion he remarks, "We see the beneficial influence of galvanization of the sympatheticus in these cases of Basedow's disease, in which the right side is affected more than the left. One of the four cases reported showed no symptoms of struma,—an absence of which, in this disease, Dusch, in his 'Lehrbuch der Herzkrankheiten,' Leipsic, 1868, says he has found only three times in fifty-eight cases, but they all manifested great disturbance in the circulation. The galvanization had especially a beneficial effect in reducing the exophthalmos and in removing the strumous condition; on the other hand, we could detect no diminution in the frequency of the pulse, nor any cessation of the palpitation of the heart, perhaps because the cases reported were very anæmic, which fact alone is sufficient to produce the distressing heart-symptoms. The crowning success of the application of galvanization in these cases is the improvement in the circulation of the blood, shown in the freshened color and the return in

one case of the menses after an absence of nearly four years, and the cessation of menorrhagia in another."

Poisoning by Vanilla.—Schroff says that the natives of Mexico and South America use a kind of oil, acajou oil, to make the vanilla bean flexible and soft, and that this oil often contains a sharp substance like cantharides. He attributes the poisonous properties of vanilla to this latter substance.

MISCELLANY.

Somnambulism and Kleptomania.—The following will remind some of our readers of a story contained in the "Ingoldsby Legends:" A retired French tradesman was lately much disgusted at finding various valuable personal articles mysteriously absent from their proper places. Residing with him was an old servant, who had lived in the house thirty years, and a nephew: it was impossible for him to suspect either, and yet there was not the slightest ground for supposing that the robberies had been effected by any one outside the house. He resolved to watch. To his consternation, he observed, one or two nights after, the nephew, in his night-dress, descend, take various valuable articles, and proceed with them to a summer-house in the garden. On his return the uncle confronted him, being duly prepared, we may suppose, for "a scene." He was disappointed. The nephew appeared utterly unconscious of his affectionate relative's presence, and passed quietly up-stairs to his room. Next day the uncle taxed him with his extraordinary conduct. The nephew denied all knowledge of it. The summer-house was searched, and in a cellar beneath it all the missing articles were found. It is bad enough to have either a somnambulist or a kleptomaniac in a family, but the two combined is really a trial which we trust, for poor humanity's sake, will remain rare.

From Japan.—A correspondent of the *Philadelphia Inquirer*, writing from Yokohama, says, "Surgeon H. C. Nelson, United States Navy, who has been in charge of the United States Hospital for some time past, left for home in the Alaska on the 7th instant, being relieved on that day by Dr. King, United States Navy. To Surgeon Nelson belongs the credit of building, organizing, and putting into active operation the finest hospital in the whole East. He has shown excellent judgment in all his selections and appointments, and the Americans of Yokohama take pride in pointing to the American flag flying over a building that is an ornament to the place.

"Dr. Simmons, an American, has been intrusted by the native officials of Yokohama with the establishment and organization of a hospital for the accommodation of sick natives. The government has under consideration the establishment of numerous hospitals and medical schools."

Cider in Rheumatism.—It has come to light that, in certain parts of England, working-people, and even little boys employed to frighten birds away, are compelled to take a considerable part of their wages in cider. Common laborers are required to take three pints per day, carters and shepherds four pints, and boys one pint. Women who work out are required to take one quart daily. Aside from the moral evils of the practice, it is found that the health of the laborers is seriously affected, and that rheumatism is a frequent result; as might be expected on the prevalent theory that that disease is caused by, or is associated with, lactic or uric acid in the blood. The subject has enlisted the attention of the House of Commons, and proceedings have been instituted for the purpose of correcting the evil.

Dartmouth Medical College.—The graduating exercises at the close of the seventy-sixth annual course of lectures at this institution were held October 30, 1872. Addresses were made by Dr. L. French, of Manchester, N. H., and Rev. Dr. Smith, President of the College, after which the degree of M.D. was conferred on twenty young men.

The Museum of Pathological Anatomy, founded by E. W. Stoughton, Esq., by the gift of upwards of ten thousand dollars, is rapidly approaching completion, and is expected to rival any similar collection in the country. The improvements made and in progress, together with the increasing number of students, give promise to this venerable school of extended usefulness in the future.

The Medical Corps of Metz.—Before the siege the medical corps of Metz numbered thirty-six physicians. Scoutetten, Félix Maréchal, Warin, and Crespy paid for their devotion with their lives. Many others fell dangerously sick. After the annexation the medical emigration commenced in advance of the popular, which latter has reduced the population from forty-nine thousand to sixteen thousand. But very few of our confrères—they whom age and association have fixed—will spend the rest of their lives in their old home. The Society of Medical Sciences, having turned over its library and archives to Nancy, has adjourned until better days.

Army Retiring Board.—The following dispatch appeared in the *Evening Telegraph* of December 14: "By direction of the President, the board to retire disabled officers, convened in Philadelphia, May 23, 1871, is dissolved. A board to retire disabled officers is ordered to convene at New York city on the 20th inst., or as soon thereafter as practicable.

"The following is the detail for the board: Major-General W. S. Hancock, Colonel Rufus Ingalls, Assistant-Quartermaster-General Colonel George W. Getty, 3d Artillery, Surgeons John M. Cuyler and John Moore."

Obituary.—Within one week the medical profession in this city has sustained the loss of two of its members.

Dr. René La Roche died on the 9th of December, at the advanced age of 77. Dr. Samuel L. Hollingsworth died on the 14th, in his 57th year. We shall place be-

fore our readers, at an early day, more extended notices of these gentlemen, who, although of late years precluded by ill health from taking part in the active duties of life, were in their day men of eminence, and whose memories will ever be held in deserved respect.

STATISTICS OF LIFE-INSURANCE.—The *Medical and Surgical Reporter* says that the Statistical Congress recently in session at St. Petersburg paid a high compliment to Mr. William Barnes, late Superintendent of the Insurance Department of the State of New York, by electing him to prepare a volume on the statistics of life-insurance in the whole world, to be presented at the next meeting, three years hence.

DR. DRUITT.—Many of our readers will regret to hear that this gentleman's health is so seriously impaired that he is obliged to spend the winter in the south of Europe. He is best known in this country by his work on surgery, so long deservedly popular as a text-book. He has for some years been the editor of the *Medical Times and Gazette*.

THERE were four hundred and seventy-six new medical students registered in the Metropolitan Schools of London for 1872,—the whole number being one thousand four hundred and ninety-six. This is the largest number hitherto registered, being one hundred and ninety-eight more than in 1870, and twenty-one more than last year.

THE GERMAN HOSPITAL.—The Board of Directors of the German Hospital in this city met recently, and among themselves subscribed $7000 towards liquidating the debt on the new hospital building.

APPOINTMENT.—Dr. A. K. Minich has been appointed on the Dispensary Staff of the Episcopal Hospital, in place of Dr. James V. Ingham, resigned.

MATTHEW and John Guy Vassar, the two sons of the man who founded Vassar College, have decided to establish a $100,000 hospital in Poughkeepsie.

MORTALITY OF PHILADELPHIA.—The interments reported at the Health Office for the week ending Dec. 14, 1872, were 290; 168 adults, and 122 minors. 11 were of bodies brought from the country; making the mortality of the city 279. Among the causes of death were:

Consumption of the Lungs	43
Other Diseases of the Respiratory Organs	54
Diseases of the Circulatory Apparatus	16
Diseases of the Brain and Nervous System	41
Diseases of the Digestive Apparatus	20
Zymotic Diseases	16
Typhoid Fever	5
Casualties	12
Cancer	7
Suicide	2
Debility (including "Inanition" and "Marasmus")	27
Malformation	3
Still-born	12
Old Age	12

(The interments reported for the week ending Dec. 16, 1871, were 497.)

THE meteorological record kept at the Pennsylvania Hospital was as follows:

	THERMOMETER. Max.	Min.	BAROMETER. (2 P.M.)
Dec. 8	43.0°	35.0°	29.90 in. (Rain.)
" 9	38.0	22.5	29.89 in. (Snow.)

OFFICIAL LIST

OF CHANGES OF STATIONS AND DUTIES OF OFFICERS OF THE MEDICAL DEPARTMENT U. S. ARMY, FROM DECEMBER 3, 1872, TO DECEMBER 9, 1872, INCLUSIVE.

MURRAY, ROBERT, ASSISTANT MEDICAL PURVEYOR.—To proceed to Washington, D.C., and report to the Adjutant-General (pursuant to instructions from the Secretary of War). S. O. 222, Military Division of the Pacific, Nov. 30, 1872.

VICKERY, R. S., ASSISTANT-SURGEON.—To accompany batteries of 3d Artillery, on Steamer "Magnolia," to New York City, and return by rail to New Orleans, La. S. O. 184, Department of the Gulf, Nov. 28, 1872.

CORSON, J. K., ASSISTANT-SURGEON.—Granted leave of absence for four months. S. O. 315, War Department, A. G. O., Dec. 4, 1872.

JOHNSON, HENRY, MEDICAL STOREKEEPER.—To perform the duties of Medical Purveyor during absence of Lieutenant-Colonel Murray. S. O. 222, c. s., Military Division of the Pacific.

LIST OF CHANGES IN THE MEDICAL CORPS U.S.N., TO DECEMBER 12, 1872.

Medical Director J. S. MESSERSMITH,—Relieved.

Assistant-Surgeon JAMES W. BUELL,—Appointed.

P. A. Surgeon B. S. MACKIE,—To the Naval Laboratory, New York.

Assistant-Surgeon P. P. BEILBY,—To the U.S. Navy Yard, Washington, D.C.

Assistant-Surgeon B. F. ROGERS,—To the U.S. Steamer Tallapoosa.

Assistant-Surgeon EDW. EVERS,—To the Naval Hospital, New York.

Medical Inspector R. P. MACCOUN,—Promoted to Medical Director.

Medical Inspector CHARLES EVERSFIELD,—Promoted to Medical Director.

Surgeon W. T. HURD,—Promoted to Medical Inspector.

Surgeon ALBERT L GIHON,—Promoted to Medical Inspector.

P. A. Surgeon C. J. S. WELLS,—Promoted to Surgeon.

P. A. Surgeon ED. KERSHNER,—Promoted to Surgeon.

Surgeon E. M. STEIN,—To Naval Hospital, Pensacola, Florida.

Surgeon T. L. DUBOIS,—To U.S. Steamer Pawnee.

Surgeon JOSEPH HUGG,—To Receiving Ship Potomac, Philadelphia.

Medical Director J. D. MILLER,—Detached from Receiving Ship Potomac, and waiting orders.

P. A. Surgeon J. W. COLES,—To Naval Hospital, New York.

P. A. Surgeon H. M. RUNDLETT,—To Naval Hospital, Yokohama, Japan.

Assistant-Surgeon G. H. TORNEY,—To the U.S. Steamer Onward.

Surgeon E. C. VERMEULEN,—Detached from Onward, and proceed home.

Surgeon J. S. KNIGHT,—Detached from Saranac, and proceed home.

P. A. Surgeon J. R. TRYON,—Detached from Hospital, Yokohama, and proceed home.

Surgeon S. ROBINSON,—To Receiving Ship Sabine, Portsmouth, New Hampshire.

Surgeon WILLIAM E. TAYLOR,—To the U.S. Steamer Saranac.

P. A. Surgeon J. G. AYRES,—Special duty, Washington, D.C.

Assistant-Surgeon J. W. BUELL,—To Receiving Ship Sabine, Portsmouth, New Hampshire.

SATURDAY, DECEMBER 28, 1872.

ORIGINAL LECTURES.

CLINICAL LECTURE

ON AMPUTATION AT THE KNEE-JOINT.

BY JOHN H. BRINTON, M.D.,
Surgeon to the Philadelphia Hospital.

Reported by FREDERICK WHELEN, Student of Medicine.

GENTLEMEN,—The first case to which I will direct your attention is that of

T. B., aged 57, intemperate, the youngest of thirteen children. States that his mother lived to be more than one hundred years old. Has never had any venereal disease, and has been perfectly healthy until about three years ago. At that time suffered a deep gnawing pain in his left leg, gradually augmenting in severity, especially at night. In a short time the limb became discolored, and an ulcer formed, which gradually increased until it has reached its present dimensions. His occupation has been that of a carter, but for the last nine months he has been unable to work. Within the last year he tells us that many pieces of bone have been discharged from the surface of the ulcer.

Such, gentlemen, is this man's past history; look now at his present condition. You can see at a glance that this is unfavorable, and that his health has been greatly impaired by his sufferings and by his confinement to his bed. His face is pale, his pulse quick and feeble, his appetite capricious and insufficient. He suffers constant pain in the leg; greatly aggravated at night. He cannot sleep, and his strength has been enfeebled by repeated hemorrhages. Upon the leg itself you observe this enormous ulcer, seven inches in length by seven in width,—almost, in fact, girdling the leg. Notice its depth, and you will see that the gastrocnemii, soleus, and tibial muscles are exposed, and in a degree destroyed. The tibia for the extent of six inches has been completely eroded; only a splinter the size of your finger now remaining. The limb is utterly useless, and the destruction, which I suspect to be of a malignant character, has been so great that reparation is beyond all hope.

Now, what can we do for this man? He is evidently running down rapidly, and without prompt and decisive surgical interference he must inevitably succumb. In my judgment, and with this my colleagues agree, there is but one chance for him; and that consists in an immediate removal of the diseased limb. The amputation in this case might be performed either through the upper third of the leg, or through the knee-joint. The latter is the operation I have decided upon, and for these reasons. In the *first* place, the disease, if of a malignant type, will, I think, be less liable to return if the amputation be at the joint than if the tibia and fibula be sawn through. *Secondly*, I am convinced that the knee-joint amputation is attended with less risk to the patient's life than amputation through the lower third of the thigh, or even through the extreme upper third of the leg, the only other possible point of selection in this case. *Thirdly*, according to my experience, the resulting stump, after disarticulation at the knee, serves exceedingly well for the adaptation of a secure and serviceable artificial limb.

Let me now say a few words to you concerning this knee-joint amputation; for it is one which I have done many times, and, I may add, with a very fair degree of satisfaction. The operation is not a novel one, for it is described as having been performed, in some sort, full two hundred years ago. It fell, however, into disuse, and was not revived until the time of the great French surgeon Velpeau. Velpeau's first operations were attended with marked success, but in his later writings he states that perhaps he had been previously too sanguine regarding the safety of this method of amputation.

In the United States the disarticulation at the knee-joint—at first regarded with suspicion—has crept steadily into favor, and articles advocating its performance have at different times been published by Drs. Stephen Smith and Markoe, of New York, by myself, and by others. In the amphitheatre of this hospital the operation has been repeatedly practised, and one of the earliest knee-joint amputations in this country was performed here more than thirty years ago, by that illustrious surgeon, the veteran professor of anatomy in the Jefferson College. In England this amputation is in high repute, and has been frequently resorted to by Messrs. Symé, Lane, Coulson, Pollock, Cooper Forster, Sir William Fergusson, and others.

In endeavoring to arrive at the real value of knee-joint amputation, you will naturally ask me, *first*, what is its mortality rate, when compared with thigh and leg amputations; *secondly*, to what class of cases is it applicable; *thirdly*, what are the dangers of the operation, and how can they be most readily avoided; and *lastly*, what sort of a stump is left after the amputation.

First, as to its Mortality Rate. Regarding this I would state that in April, 1868, I collected and published in the *American Journal of the Medical Sciences* the records of 117 cases of amputation at the knee-joint performed by American surgeons. The resulting death-rates were,—for primary amputations after accident, 44 per cent.; secondary after accident, 42; secondary amputations for disease, less than 17 per cent.,—an average mortality of about 34 per cent. in the 117 cases. The mortality rate in 164 cases, American and foreign, was about 32 per cent. It will be found by comparison that these percentages of death are greatly below those of amputation in the continuity of the thigh, and I think also much less than the ratio furnished by the result of amputation through the upper third of the leg in the vicinity of the joint. So far, then, as a patient's chances of life are concerned, especially in cases of secondary amputations for disease, it seems to me that the amputation in question is from every point of view eminently proper.

Secondly, to what *class of cases*, and under what circumstances, is the amputation at the knee-joint applicable? The answer can be broadly given: to very many cases of injury or disease which have usually been regarded as necessitating amputation at the lower third of the thigh. In this category I would include—1. Cases of crushed, compound, and gunshot fractures of the leg bones, extending up to or involving the knee-joint. 2. Gunshot wounds of the knee-joint. 3. Gangrene of the leg, the result of injury to the great vessels or nerves. 4. Chronic or irreparable diseases of the bones, or tumors of the leg. 5. Degeneration of the knee-joint.

Our *third* topic of inquiry is concerning the dangers of the disarticulation at the knee. In all large amputations, as you well know, there is a certain inevitable amount of *shock*; but in the operation in question, this subsequent shock would seem to be diminished in an extraordinary degree. Whether this be due to the comparatively slight section of the muscular tissue, or to the preservation of the continuity of the shaft and medullary cavity of the femur, or to both, I cannot tell, but I am quite sure that the shock of this operation is comparatively less than that in amputations of the leg or thigh. Then, too, I think that in this disarticulation, as in all other amputations in contiguity, there is less likelihood of pyæmic poisoning. The cancellated and medullary structures are alike spared, the risk of osteo-myelitis is unquestionably decreased, and the chances for the patient's life are proportionately improved.

It has been alleged by many surgeons, but, I think, without due consideration, that the occurrence of synovial inflammation is to be feared in this connection. Regarding this, I can only say that I have never encountered any grave symptoms which could be referred to such a cause. Indeed, how could they exist? when it is evident that the operation itself destroys the articulation, and that in a very few days—I might almost say hours—all traces of the synovial membrane disappear.

There is, however, one accident, not infrequent after amputation at the knee, which deserves your attention. I refer to inflammation of the sheaths of the thigh tendons, especially of that of the biceps muscle, and to inflammation of the bursa over the patella. This inflammation, marked by tenderness, pain on pressure, excessive swelling, arrest of discharges from the stump, and considerable constitutional irritation, occurs between the second and fifth day after operation. It is sometimes so severe as almost to compromise the patient's welfare. The treatment consists in early and free evacuation of the abscesses, and in the proper constitutional support.

The healing of the stump of a knee-amputation is full of interest. Sometimes, although very rarely, a union by first intention may happen. Most often, however, only partial union of the flaps takes place, while, here and there, patches of slough separate at their edges. The articular cartilage is thus left uncovered. Sometimes it softens, becomes thinner, and disappears molecularly, the vessels on the end of the bone beneath the softening cartilage gradually becoming more distinct, and serving as the support for granulations of rapid growth, which spring from the bone to coalesce with other growths from the soft tissues of the inter-condyloid notch. In other cases, on the eighteenth or twentieth day, the articular cartilage, having softened and become sodden, separates in layers from the bone, and may be drawn away by the forceps. Granulation, as already described, then takes place.

You will naturally ask me, what kind of a stump does this knee-amputation give? My answer is, A good one, a very good and useful stump, and one in which, if you are careful to preserve the insertion of the round tendon of the adductor magnus, a great degree of motion, and especially of rotary power, will be obtained. There are now in this city a number of persons upon whom I have performed this operation, and the character of the stumps is very gratifying.

Here let me say a few words to you as to the choice of a mode of operating. Your main object will be so to manage your incisions as to procure a large and, indeed, at first sight a redundant skin covering. This you may do either by the lateral or by the antero-posterior flap method. I shall this morning employ the latter. The lateral flaps have the advantage of affording a good drainage; but should sloughing occur, and to some extent it does in nearly all cases, the condyles are apt to project. The cicatrix too, by the lateral flap plan, falls on a point of future pressure; whereas, by the other method, it will be found behind and rather above the articular line. We will, therefore, employ the antero-posterior flap.

Our patient is now etherized, his leg has been well elevated to drain off the blood, and I tighten the tourniquet, which you notice is adjusted in the ham over the popliteal vessels, a point of application which I greatly prefer. Notice, if you please, now, my mode of incision. Standing upon the right side of the limb, I enter my knife below the head of the fibula, and, sweeping it around anteriorly, cut from the front of the leg a large integumental horse-shoe flap, terminating my incision over the inner head of the tibia. This flap I dissect up, and I then divide successively the ligament of the patella, the crucial and the coronary ligaments. Next, grasping the leg in my left hand, I carry my knife through the joint, and cut *directly backwards*, so as to divide the popliteal artery; I then turn the knife edge downwards, and cut out a short and broad flap, say three inches in length. This flap contains the heads of the gastrocnemii. These I immediately remove, since I wish the flap to be integumental only. I then ligate the bleeding vessels, consisting of the popliteal artery and vein, the superior muscular, sural, and superior articular arteries, and take off the pressure of the tourniquet. The venous oozing ceases, and the closing and dressing of the stump can be proceeded with after a proper interval.

Let me now add a few words as to one or two of the steps in the above procedure. Thus, I began and terminated the incisions of my anterior flap

well below the joint, in order to insure a perfect condyloid covering. I divided the *coronary ligaments*, so as to allow the semilunar cartilages to *remain* upon the articular end of the femur, and in the stump. By thus leaving them in position I have a cap fitted upon the end of the femur, which preserves all the fascial relations, effectually prevents retraction, and guards against the projection of the condyles. I insist somewhat strongly upon this retention of the semilunar cartilages, since I regard it as having an important bearing upon the future well-being of the stump. Then, too, you noticed that I divided the popliteal by carrying my knife *directly backwards*, instead of turning its edge downwards as soon as the posterior ligament of the knee had been traversed. My object was to divide the popliteal vessel *above the points of origin* of the azygos and inferior articular arteries, which, as you know, are distributed to the interior of the joint. Experience has convinced me that perhaps the most annoying feature in knee-joint amputation is the occasional tendency to secondary oozing from the minute vessels which ramify upon the intercondyloid tissues. These vessels, too small at the time of operation to require ligation, are apt to enlarge as the collateral circulation becomes established, and thus give rise to troublesome bleeding, for which in two or three cases I have been obliged to open the stump. By the high section of the popliteal, as above practised, this vascular supply is cut off, and the liability to this secondary hemorrhage obviated. The gastrocnemial origins I remove in consequence of their tendency to become irritated, their awkward fitting upon the stump, and the excessive suppuration they give rise to. It is much better to get rid of them, for I am quite sure that flaps formed from the muscular tissue of the calf do not, as a rule, do well.

You observe that I have tied the popliteal vein. Experience has taught me that the vein in this amputation is peculiarly liable to gape and bleed unless tied. Whether this tendency to hemorrhage be owing to the firmness of the tissues by which the vein is surrounded, to its numerous branches, or, as Mr. Carden has suggested, to the jar of the popliteal pulsation, I cannot tell. I know that the ligature will prevent the bleeding; I have applied it many times already; and, as I have yet to see the first evidence of trouble, I have had no hesitation in applying it again this morning.

There is yet one other matter, to which I will just allude. You have seen that I have left the condyles of the femur untouched, and that I have not sawn them off. Some of my surgical friends may, and indeed they do, criticise me here, urging that a flatter and a better stump may be insured if the condyles be removed. In answer to them, I can only fall back again on my experiences, which have taught me that a prompt convalescence and a serviceable stump may often be obtained by the procedure I have indicated to you this morning. Indeed, I will go a little further, and say that a very careful comparison of all recorded instances of knee-joint amputation shows that although there is but little difference in the mortality rate of the aggregate of all cases in which the condyles have been left, and of all those in which they have been removed in whole or in part, still that difference is in favor of the former method.

As to the patient before us, I scarcely dare venture a certainly favorable prognosis. We have given him his chance, but it is only a chance. The nature of his disease, its extent, and his general condition are against him, and no one can foretell the issue of his case. Let us hope for the best.

ORIGINAL COMMUNICATIONS.

CASES OF CEREBRAL MENINGITIS.

BY JAMES D. McGAUGHEY, M.D.,
Wallingford, Conn.

THE following cases, that occurred sporadically in country practice, differ in many respects from ordinary simple idiopathic meningitis, and may offer some points of interest. The cases came under my notice while practising South, in a region of country celebrated for the salubrity of its climate and its freedom from epidemics. They did not make their appearance simultaneously or follow each other rapidly, but showed themselves in irregular periods during a space of twelve or fifteen months.

Dr. B. F. Bell, a neighbor and friend, related to me the history of three cases that came under his notice shortly after I saw my first case,—two children and an aged gentleman, with the death of one child and the adult. Several months thereafter I saw my second case, and a month or two subsequently Dr. E. B. Smith treated a case of a young man that proved fatal. Following this one came my third case; and a month or two later I was called in consultation to see a negro child which lay in deep coma, eight or ten days before death. Now, it seemed to me—the cases being scattered over a period of time amounting to thirteen or fourteen months, some in the spring, summer, autumn, and winter—that no peculiar poison in the air, with other modifying tendencies, existed sufficient to cause an endemic or epidemic form of cerebro-spinal meningitis. Two-thirds of the cases coming under my observation had a clear history of either pulmonary tuberculosis or scrofula. One case made its appearance shortly after the discharge of a tuberculous deposit and an apparent healing of the vomica; and another after the discharge and healing of a large scrofulous abscess of the hip. Such cases seemed proof, presumptive proof, against epidemic influence, although the history of some of the cases seemed to approach almost identically to that of some of the cases occurring in cerebro-spinal epidemics. Perhaps, though, a *cerebro-spinal tendency* existing for a period of twelve or fourteen months *may have been the cause* of the susceptibility of those suffering under tuberculosis and scrofula to become the subjects of fatal meningitis. Extending the space

of time from fourteen to twenty-two months, I can count twelve cases of meningitis—cerebral—coming up within a space of seven miles square of a rather thinly settled district, with the result of *eleven* deaths and *one* recovery; one case, the first of the series, in a child one year old, was pronounced to be cerebro-spinal meningitis by the attending physician, a competent man. The cases I saw, in their history and symptoms, resembled sporadic cases of tubercular meningitis more than cases of cerebro-spinal fever.

The following cases I mention are more for individual peculiarities than to discuss their identity with cerebro-spinal meningitis, or to show that the atter was epidemic, or to say anything of the *phenomena peculiar* to that singular disease.

Case I.—W. N., girl, aged 10 years. Complained a day or two of cephalalgia and pain in the limbs. This was on Sunday and Monday. During Tuesday, though walking about, appeared at times delirious. Tuesday night, in bed; lies quiet. Complains of pain in the head; has mild delirium; head not unnaturally hot; eyes, pupils somewhat dilated, and tolerant of light; ears tolerant of sound; face but little flushed, rather pale; tongue coated heavily; respiration regular; had been vomiting; constipated; abdomen swelled, and intensely red all over its surface; almost continuous contraction of the flexor muscles of the right forearm; pulse frequent, but no unusual pulsation of the carotids. A singular phenomenon of the case was the metastasis of the pain from the head to the right hip; and when the pain was in the hip it seemed to be much more acutely painful than when in the head. The muscles of the legs were sometimes spasmodically contracted, continuing in this condition for a considerable space of time, then a relaxation, which in its turn was succeeded by contraction. Thus the case progressed, with a return to consciousness after cold constantly applied, purging, and blistering, but in a short time relapsed into the same condition, with increased frequency of pulse, somnolency, and drowsiness. This condition lasted several days, with considerable conscious intervals, but the somnolency deepened; asthenia made rapid advance; pulse small, and very frequent; eyes glazed, sordes, carphology, and death; profoundly unconscious.

Remarks.—This case did not follow nor show the general order of symptoms of acute idiopathic cerebral meningitis, as laid down in the books. There was no wild delirium; no rapid, bounding, full pulse; no throbbing carotids; no injection of the eyes; no intolerance of light or sound. It seemed in some respects to resemble the phrenitic form of Rilliet. Complete consciousness was not abolished till just a day or two before death, and there were but few symptoms indicating effusion. As the case did not closely resemble acute idiopathic cerebral meningitis, neither did it have the appearance of cerebro-spinal meningitis: "the onset was not sudden," nor "the course rapid;" indeed, there were many and peculiar symptoms of cerebro-spinal fever that were absent in this case, not necessary to mention. On the mother's side there exists *strong tubercular predisposition*, and a *scrofulous diathesis* on the father's side, and, after taking into consideration the complete history of the case, with a close study of it as it presented itself before the eye, I concluded that the diagnosis of tuberculous meningitis would be more correct than that of any other form of meningeal inflammation. C. J. B. Williams, in his work on Pulmonary Consumption, gives, in Case 71, the history of a boy, aged 13, who, *without any premonitions of tuberculosis, was attacked* with meningitis, and died in twenty-one days. On a post-mortem being made, partially *granular tubercles were found at the base of the brain; granular tubercles scattered through both lungs. "One caseous tubercle in right lung; and the right bronchus was also enlarged, with cheesy matter."* Williams remarks on the case, "This case is remarkable *for the entire latency of the pulmonary tubercles*, which must have existed before the commencement of the fatal attack of meningitis." I feel pretty well assured that, if a post-mortem had been permitted, the lungs and brain would have been found in a tubercular condition, although I had no proof of such an assertion, except the strong family predispositions, and the *pale, delicate condition* of the child *before* the meningeal attack. When the pain transferred itself from the head to the hip, it became atrociously painful, extorting cries from the patient. The hip—the right one—was carefully examined by three other physicians besides myself, but no organic trouble could be discovered, neither in the hip, appendix vermiformis, nor any neighboring organ. These curious epiphenomena of pain in the limbs and joints of those suffering under cerebral and spinal disease are very puzzling, and often distressing, and are not easily explained. Mercury was thoroughly tried in this case, without any benefit whatever.

Case II.—Child, 10 months old. Was taken, nine days before my first visit, with vomiting and purging. I could get no accurate history from that time up to my first visit, only that the child seemed to suffer a great deal. When I saw it, it had lost flesh and was weak. Respirations frequent; tongue brownish, dry, and coated; lips and mouth dry; vomited yesterday and to-day; pulse frequent, and weak. Head thrown back spasmodically—lies in this position all the time; eyes rolled up; jumps and starts in sleep; grinds the gums constantly; protrudes its tongue to the full length, and withdraws it, all the time; eyes bright; frets and cries; will not suck; scrofulous abscess on the neck; quantity of urine small; anterior fontanelle raised and strongly pulsating. As the disease progressed, the pulse became more frequent, respirations irregular; convulsions, and vomiting. Convulsions increased, and child sank rapidly.

Remarks.—This case derives interest principally from its history. A month or two previous to the meningeal attack, a very large *scrofulous abscess* formed over the hip, which, on being opened, discharged a large quantity of pus. On this healing up, another abscess appeared on the side of the neck, just posterior to the angle of the jaw; this opened itself after a while, and continued to discharge matter until the meningeal trouble came up, when it ceased, and could not be stimulated to discharging again. As there existed no cause that could explain the case as one of acute idiopathic meningitis, —this disease being rare without a cause, such as blows, insolation, reflex irritation, etc.,—and a strong scrofulous diathesis pre-existing, I con-

cluded the case to be one of tubercular meningitis, although the invariable custom of the country of not allowing post-mortems precluded the possibility of my confirming my diagnosis by actual dissection. No fault could be found with the teeth as a cause; the gums were not swollen. Iodide of potassium seemed not to do the least good. Another symptom of some value was the gradual loss of flesh the child had suffered for some weeks previous to the brain-trouble.

(To be continued.)

FLUID EXTRACT OF CASTANEA VESCA IN PERTUSSIS.

BY THOMAS D. DAVIS, M.D.,

Dayton, Ohio.

HOOPING-COUGH has already so many vaunted remedies, that I hesitate to call attention to one but slightly noticed heretofore. There are so many sources of fallacy in estimating the effect of a medicine in this disease that very many cases are required before a correct conclusion can be obtained. The fickle nature of the disease itself, the surroundings of the patients, and their food, clothing, and attention, all exercise a powerful influence on the course and severity of the attack. It is impossible, therefore, to compare the value of a remedy in the pampered child in its luxurious home, to its effect among those in the lower walks of life, who frequently have improper food, thin clothes, and insufficient warmth. Hence it is with more satisfaction that I present the following fifteen cases, as they were all exposed to the same surroundings, having the same kind of food and clothing, living and sleeping in the same rooms, and all receiving the same care and attention.

In the winter of 1870, while a resident physician in the Philadelphia Children's Asylum, an epidemic of pertussis broke out among the children. They were treated with different medicines until the disease was well marked and some of the cases had assumed a severe type. So severe were the paroxysms that several of the children's eyes were black and blue and very much swollen and congested, from forcing the lids together and pressing them with their hands during the fits of coughing. At this stage, on the suggestion of Dr. J. S. Parry, one of the visiting physicians to the institution, they were put upon the use of the fluid extract of castanea vesca. In order that we might judge correctly of the drug, for two days before using it all medication was stopped. The disease immediately increased, both in the number and severity of the paroxysms. The children were all otherwise healthy, and between four and seven years of age. I have tabulated the cases, so that there can be seen at a glance the number of paroxysms in each case while on the use of belladonna, without it, and for five days after using the other remedy:

Number of Cases.	Paroxysms using Belladonna.	Without Medicine.		Using Fluid Extract Castanea Vesca.				
		1st day.	2d day.	1st day.	2d day.	3d day.	4th day.	5th day.
1	16	20	27	19	11	9	5	2
2	14	24	24	20	9	4	4	2
3	13	13	17	12	5	4	1	1
4	12	16	20	10	6	3	2	0
5	12	18	18	7	4	5	2	1
6	12	15	20	9	5	3	1	2
7	11	11	18	6	4	2	1	0
8	10	9	12	7	2	0	1	0
9	9	12	13	5	4	2	1	0
10	7	9	10	2	2	2	0	0
11	7	8	15	4	3	1	0	0
12	5	6	10	3	1	1	0	0
13	5	7	6	2	0	0	0	0
14	3	4	4	3	1	0	0	0
15	2	4	5	4	2	0	0	0

In this table the cases are arranged in the order of their severity while on the use of belladonna. The first eleven cases all had the characteristic whoop; the remainder had well-marked paroxysms, but not the full spasm, and they recovered without having it. In each case the violence of the spasm was reduced even more markedly than the number of the paroxysms. On the days on which the cases are marked as having no paroxysms, they had slight coughs, but no sign of spasm whatever. The castanea was continued for a week, after which, in a few cases, a simple expectorant was given. The nurse in charge, who had witnessed many epidemics of the disease, declared she had never seen a medicine act like it.

This medicine is made from the leaves of the common chestnut-tree,—Castanea vesca, natural order Cupuliferæ. Another species of this genus, Castanea pumila (chinquapin), for some time held a place in the secondary list of our Pharmacopœia; the bark of this was an astringent and tonic, and was employed also in the cure of intermittents. The first mention I can find of chestnut leaves as a remedy was in a paper read before the American Pharmaceutical Association, in 1862, by Mr. George C. Close, of Brooklyn, N. Y. (*Am. Jour. Pharm.*, 1863.

p. 66). They were recommended to him as a cure for pertussis by a "prominent physician of New York," whose success with them had been very marked. He administered an infusion of them made with boiling water and sweetened with sugar, and reports that in every case it "acted like a charm."

Dr. J. Unzicker, of Cincinnati, called attention to this remedy, with a very favorable account of its virtues, in an article written in 1867 (*Med. and Surg. Reporter*, October 26, 1867, p. 355). He claimed that it had never failed in his hands to cure or relieve the spasm and bring the disease to a speedy end.

Dr. J. Ludlow, of the same city, commended it highly in articles written two years later (*Cin. Lan. and Obs.*, March, 1869, p. 147, and *N. Y. Med. Jour.*, April, 1869). He gives the credit to Dr. Unzicker for having brought it to his notice first, and says, "In every case that I have treated since, I have invariably used it, and with the happiest result,—in from five to ten days relieving the spasm, and in about two weeks curing it." All of these observers used an infusion of the leaves.

In a paper presented to the Philadelphia College of Pharmacy, Nov. 21, 1871, by Mr. John M. Maisch (*Am. Jour. Pharm.*, Dec. 1871, p. 529), he announces that since 1867, at the request of Dr. A. S. Gerhard, of Philadelphia, he had collected chestnut leaves, and had prepared of them an infusion, syrup, and fluid extract, of which he greatly preferred the latter preparation. He speaks in the highest praise of the medicine in hooping-cough, but mentions two cases in which it did not appear to be of benefit. Mr. Maisch is the only druggist who has preparations of this article: it was his fluid extract that we used in the cases reported. The leaves are gathered from July to October, the preference being given to those procured late in the season. The following is Mr. Maisch's formula for making the fluid extract: Chestnut leaves, dried, cut, and bruised, sixteen ounces; glycerin, five ounces; sugar, eight ounces; and hot water, a sufficient quantity; the extract to measure sixteen fluidounces. His method of preparing this extract is given in his paper. The dose is half a teaspoonful to a teaspoonful every three or four hours, for a child six years old. In urging this remedy upon the notice of the profession, we do not claim for it a specific action, but think it will be found a valuable anti-spasmodic and expectorant, the preparations of which are not unpleasant, and are, therefore, readily taken by children. In the cases we have cited, we are sensible that in the most of them treatment was begun in the height of the disease, and we might consequently expect a decrease in its severity, but scarcely such a marked decline as our cases indicated under the use of chestnut leaves. As a domestic remedy, an infusion of the leaves has been used for many years in regions of the country where this tree flourished.

THE *Dublin Gazette* has published an order prohibiting the importation of horses from America.

NOTES OF HOSPITAL PRACTICE.

JEFFERSON MEDICAL COLLEGE.

SURGICAL CLINIC OF PROFESSOR S. D. GROSS, M.D.

Reported by FRANK WOODBURY.

TRACHEOTOMY.

THIS boy, five years of age, comes to us with a probable history of having inhaled a button or a large bead into his trachea. Twenty-six days ago he came running into the house and told his parents that while holding such an article in his mouth it slipped down the throat, producing a severe attack of coughing, with symptoms of strangulation. This statement was not credited; but a subsequent attack, five hours afterwards, seemed to confirm it. These attacks, of which he has had several since, are attended with great dyspnœa, with apparently impending suffocation, and are evidently caused by the article coming up against the glottis in expiration. Within a few days, symptoms of pneumonia, with fever, cough, and solidification of part of the right lung, have supervened, inducing the attendant to summon me last evening, in consultation. After examining the patient, I concluded that the foreign substance had not yet been expelled, and recommended opening the trachea for the purpose of extracting it. I told the parents that the child might, during one of these attacks of coughing, suffocate in an instant from spasm of the glottis, but, if not relieved, he would, in a short time, certainly perish from the induced pneumonia. I therefore advised tracheotomy to remove the offending substance as the only chance of saving the patient, and I have brought him before you with the object of performing that operation.

On applying the ear we find at the right side of the chest that the respiratory murmur is indistinct, and there is evident bronchophony; there is not absolute percussion-dulness, because in these cases the air never entirely escapes from the lung. He has the rusty sputum this morning, making him an unfavorable subject for operation, as we may not be able to control this pneumonia even after removing the article. Recorded cases show that when the operation is performed immediately after the accident, it is far more likely to be successful than when delayed until the occurrence of inflammation.

The foreign substance may, in a coughing-fit, be expelled unconsciously by the patient, or it may be extruded from the air-passages and slip down the œsophagus unnoticed into the stomach. In either event, the resulting local inflammation, produced by the parts resenting the presence of the intruder, may maintain the irritation and strongly simulate the original symptoms. This fact makes us reluctant to operate, unless we observe the characteristic rattling sound produced by the motion of the substance upward and downward in the trachea during expiration and inspiration. The time since its introduction, in the present case, is sufficient for it to have become plugged in one of the larger bronchi from the increased secretion of mucus, which has probably taken place since those violent attacks of coughing have ceased. The diagnosis is always obscure in these cases; but the symptoms here warrant the operation, especially as the wound is not necessarily dangerous. The article may be expelled during the violent fit of coughing which always ensues upon opening the trachea, or perhaps not for several days, or not at all; it may either come through the opening or through the mouth, or may pass unnoticed down the throat.

The left bronchus is given off from the trachea quite

obliquely, while the right one is almost a direct continuation of the tube; this explains why a foreign substance generally falls into the right bronchus and affects the right lung.

Tracheotomy is a delicate, and in some cases a most difficult, operation, especially in croup,—where the patient has generally a short, fat neck, and keeps constantly crying and struggling. Amputation at the hip is much easier to perform. Having the patient recumbent and well influenced by ether, the trachea is made prominent by elevating the shoulders and throwing the head back. The external incision should extend along the middle line from the cricoid cartilage almost to the top of the sternum. The ribbon-like muscles are separated and the deep cervical fascia divided on a grooved director, when the thyroid plexus of veins are seen, which must be pushed to one side, as they are congested, and if cut would bleed freely. Occasionally the inferior thyroid artery is replaced by a small branch arising from the innominate artery, arch of the aortæ, or left subclavian, which passes up in front of the trachea to the thyroid gland: this is named, in honor of the German surgeon who first described it, the artery of Neubauer, or the middle thyroid, and is present in one out of four or five cases. If this is cut it must be secured, with any other bleeding vessels, and all the blood removed from the wound before the trachea is opened; this is of great importance. Fixing the trachea with the volsella, a probe-pointed bistoury is entered at the lowest point, with its back to the great vessels, and four rings of the trachea are opened, being careful to avoid wounding the isthmus of the thyroid gland. The patient is then immediately turned on his side,—not on his belly,—to avoid bleeding into the trachea, the inhalation of a single drachm of blood having been known to cause death. The mucous lining of the tube, from the continued irritation, is generally congested, and bleeds freely. The edges of the trachea are held apart by a pair of forceps during the violent fit of coughing, which extrudes a quantity of mucopurulent fluid, but not the foreign substance. The patient is inverted, succussion and percussion of the chest are practised, without the desired result. Ingenious instruments have been devised to explore the trachea, a number of which I here show you; they may be useful in some cases, but they are capable of inflicting irreparable mischief.

An anodyne will be given immediately, and the patient kept in a room whose atmosphere shall be kept moist and at about 85° Fahrenheit. The article may be expelled at any time before the closure of the wound, over which a fine piece of gauze is placed, to exclude dust, etc.

A curious circumstance connected with the operation is that the irritability of the larynx and tendency to reflex spasmodic closure cease the moment an incision is made into the trachea, so that instruments may now be introduced into the glottis with impunity. The parts, therefore, are in a better condition to tolerate the presence of the intruder, and a fatal result from spasm of the glottis need no longer be feared. Before the operation the patient is never safe so long as the substance remains, as instant suffocation may ensue upon a fit of coughing. In 1854 I analyzed all the cases on record, and found that this result had occurred in a large proportion of them.

Nov. 2.—The patient died five hours after the operation, from exhaustion.

At the post-mortem examination the wound was found ample for the extrusion of the substance, which was discovered deep, but not exactly impacted, in the right bronchus. The offending substance was this black glass bead. It measures about one-half an inch in length, and is perforated and elliptical in shape. About four ounces of fluid containing flakes of fibrin were found in the right thoracic cavity, showing the extension of the inflammation to the pleura.

FALSE ANCHYLOSIS OF THE HIP-JOINT.

This young woman has had trouble in her left hip for three years, which has resulted in total inability to move the limb.

You observe that the gluteo-femoral crease on the affected side is absent: there is no line of demarcation or fold between the buttock and thigh. The great trochanter is unusually prominent. This portion of the femur is liable to disease such as necrosis, or chronic inflammation of a strumous or syphilitic character. This might go on to thickening of the tissues of the joint, and even lead to anchylosis from extension of the inflammation, or it might result in tuberculosis and produce coxalgia.

In the treatment of this osteitis, or periosteitis, of the great trochanter, counter-irritation is especially useful. Vesication may be tried; but the actual cautery is much better, making an issue to last several months. Inflammation extending to the neck of the bone may produce softening and interstitial absorption, with consequent shortening; this may also be produced by a fall or violence, or arise spontaneously, as in old persons. After an injury the surgeon may assert that the bone is not broken, and yet shortening and deformity may follow, leading the patient to the belief that there was a fracture which the attendant failed to recognize and to treat properly. In this way, a few years ago, several gentlemen were sued for malpractice; but no damages were obtained, and it would have been very unjust if any had been allowed.

There is no syphilitic history to the case; nor is this a strumous affection of the joint, or there would have been an abscess formed here long ago. It is probably rheumatic or due to an injury which has been forgotten. I bring her before you for the purpose of breaking up these adhesions in the joint, under chloroform. I find some mobility but no voluntary motion in the joint. On rotating the limb there is a grating sound, produced by the presence of organized lymph; there is partial destruction of the synovial membrane, and the articular surfaces are dry from absence of synovial fluid.

Having flexed the joint and broken up the adhesions, we will order passive motion to be practised twice every day, in order to prevent their re-formation. The limb is to be washed every day with Castile soap and water, and the joint rubbed several times daily with,

℞ Tr. saponis camph., f℥iv,
Spts. ammoniæ, ℥j. M.

and as a tonic,

℞ Tr. ferri chlorid., gtt. xx,
Hydrarg. chlorid. corros., gr. $\frac{1}{20}$. M.
S. t. d.

ENCEPHALOID TUMOR.

This middle-aged gentleman comes from southwestern Virginia, on account of a tumor occupying principally the left temple. This commenced eighteen months ago as a little nodule, without apparent cause; and is now as large as a goose-egg. It is situated over the zygoma, and extends forward and upward on the cheek, and backward behind the lobe of the ear, and deep under the parotid gland and beneath the sterno-mastoid muscle. The skin over it is discolored, and, in one spot, ulcerated. It is quite solid above and tender to pressure. It has not been attended with much pain, which occasionally is dull and aching. An ineffectual attempt was made to remove the tumor seven weeks ago, but it was rapidly reproduced. There are no enlarged cervical glands.

Whether this commenced in the cellular tissue or in the parotid gland, I am unable to say, but it is certainly malignant, and either an encephaloid or a round-celled sarcoma. I do not deem it proper to interfere in this case with the knife, as it would quickly return after operation; all that can be done is to make the patient comfortable.

Mr. Broadbent, of London, some years ago recommended injection of a few drops of acetic acid into the substance of malignant growths, to accomplish their disintegration and destroy the morbid action. A diminution of the size of the tumor is reported in some of his cases to have followed this treatment, but in the few cases in which I have tried it I have failed to perceive any good result.

ADENOMA.

This patient, æt. 70 years, complains of a constant, and at times intense, pain in this swelling on the side of the neck, which commenced three months ago. There is a hard, circumscribed tumor, partially under and behind the sterno-mastoid muscle, and somewhat movable.

This is probably a diseased lymphatic gland, but, as it may take on malignancy, it is best to remove it. In operating upon the neck, always have the jugular vein compressed so that, in case it were accidentally cut, no air would be drawn into the circulation. If this did happen, it would cause the death of the patient in the twinkling of an eye, from the mechanical obstruction to the circulation, produced by the air-bubbles. We find the tumor deep-seated, and extending towards the pharynx, whence we will carefully remove it by enucleation and avulsion. It is a gland in a state of enlargement and partial suppuration. The wound is united by sutures, and allowed to heal under a water-dressing. An anodyne will be given as soon as the patient recovers from the influence of the anæsthetic.

Perforation of the Frontal Bone by a Gun-Shot Wound (Lederer: *Wiener Mediz. Presse*, Oct. 13, 1872).—The following case shows how great an injury the human organism may survive:

"A hotel-keeper, who had the misfortune to live in a very disorderly district, was annoyed one night by the abusive language of a man and a woman who had stationed themselves under the inn-keeper's window for the purpose of annoying him. The landlord, greatly incensed at this conduct of his patrons, seized a loaded double-barrelled gun from the wall and fired at random into the darkness of the night. One shot struck the man on the right temporal region and orbit, and left behind many traces in the shape of shot, which penetrated from one line to one line and a half into the skin. The second shot had felled the woman to the ground. I was called immediately to the latter. I found her lying on the floor in her own house, fully conscious, and was able by the light of an ordinary candle to see that the frontal bone above and between the eyebrows was broken through, in a direction from right to left, and outward and inward. I was able to thrust my finger an inch into the wound without meeting anything but splinters of bone. What the gun was loaded with remains a mystery to me to the present moment. And, improbable as it may seem, the load, after it had fractured the frontal bone, fell from the wound and was lost. The edges of the wound were blackened by powder, and the hemorrhage was slight. After removing the splinters of bone I filled the wound with charpie and ordered it to be dressed with compresses steeped in ice-water, which was continued during all of the next day.

"The hemorrhage ceased entirely, and never returned, and, without any loss of consciousness on the part of the patient at any time, suppuration set in, in the wound, after a few days. At night there was some delirium, but I always obtained perfectly intelligent answers to all my questions put to the patient. In the course of time, as the suppuration became more copious, the cold-water dressings were abandoned, and careful cleansing by means of tepid water carefully kept up, small doses of morphia administered, the diet regulated, and, as from the beginning, the strictest quiet enjoined. In the course of a few weeks, several pieces of bone came away from the depth of the wound, which were, in all probability, pieces of the wings of the sphenoid bone; and now I beheld a spectacle which should have been seen with one's own eye in order to have been fully appreciated. I saw at the fundus of the wound, which was about one inch and a half in depth, the fissure between the hemispheres of the brain, and parts of the anterior and inferior surfaces of the hemispheres of the brain, covered with the arachnoid and pia mater,—the dura mater having been destroyed during suppuration. I also saw one of the larger arteries pulsating synchronously with the systole and diastole of the heart, and the entire brain was distinctly visible in its motion, forward and backward, as well as upward and downward.

"Since some pus still remained in the deeper parts of the wound, at each recoil of the brain a little air-bubble formed, which burst with the well-known gentle noise at each forward movement of the brain. The patient was seen repeatedly by me, and the phenomenon observed with great interest, until at last granulations hid it from view. By the 24th of October the wound had nearly filled up with granulations, and, the patient moving to another town, I lost sight of the case."

Seven Tæniæ in One Patient, without Symptoms.—The following case is quoted in the *Boston Medical and Surgical Journal* from the *Journal de Méd. et de Chir. Prat.*, July, 1872:

The patient, a hospital nurse at Lariboisière, aged 25 years, had been ill for a few days, with general lassitude, with pains in the epigastrium and left chest. There was no morbid manifestation to draw attention to the alimentary canal; and none of his antecedents led to the suspicion that he was infested with intestinal worms. One morning he noticed in his dejections flat, ribboned, and white masses, which proved, on examination, to be fragments of a tænia. He was ordered twenty grammes (about five drachms) of kousso, very finely powdered, infused in about eight ounces of boiling water, and allowed to stand over-night. He took the whole, powder and all, warmed up and well mixed. In an hour and a half he experienced a little intestinal commotion, and some colicky pains. A dejection soon followed, with considerable masses of interlaced tæniæ. A second dejection, half an hour afterwards, brought away still more. A dose of castor-oil, now given, produced liquid evacuations without further fragments of worms.

On examination of the vermicular mass under water, seven heads of tæniæ were detected, which were also verified by the microscope. The tæniæ, unrolled, measured from one and a half to nine yards in length; or a total, with the other fragments, of about twenty-two yards.

The next day the patient returned to his occupation. On further inquiry, no indications could be discovered which, if previously known, would have led to a diagnosis. He had never partaken of raw meat, nor often eaten sausages.

The case is remarkable for the number of entozoa, and for the readiness with which they were dislodged. The latter may be due to the fineness of the powdered drug and the long time allowed for its infusion.

PHILADELPHIA
MEDICAL TIMES.
A WEEKLY JOURNAL OF
MEDICAL AND SURGICAL SCIENCE.

The Philadelphia Medical Times is an independent journal, devoted to no ends or interests whatever but those common to all who cultivate the science of medicine. Its columns are open to all those who wish to express their views on any subject coming within its legitimate sphere.

We invite contributions, reports of cases, notes and queries, medical news, and whatever may tend to increase the value of our pages.

All communications must bear the name of the sender (whether the name is to be published or not), and should be addressed to Editor Philadelphia Medical Times, care of the Publishers.

PUBLISHED EVERY SATURDAY BY
J. B. LIPPINCOTT & CO.,
715 and 717 Market St., Philadelphia, and 25 Bond St., New York.

SATURDAY, DECEMBER 28, 1872.

EDITORIAL.

THE PUBLIC MEDICAL SERVICE.

CERTAIN duties have to be rendered by physicians to the public, or at least in the public behalf, which ought, as it seems to us, to be placed on a different basis from that upon which they rest at present. These duties vary widely, and are often of great importance; but we propose now to speak of but two of them, with regard to which we think the existing system can be easily shown to be faulty.

In the first place, as to post-mortem investigations made by order of the coroner. We urge that the medical man employed to attend to this duty should be a sworn officer, duly and formally appointed, and with one or more deputies similarly qualified. It is by no means certain that the free choice of the incumbent of the coroner's office would always be so unobjectionable as at present. Dr. Shapleigh has for many years steadily won upon the confidence of the community, by his fidelity in carrying out the often unpleasant tasks intrusted to him. We should like to see him made, by appointment, say from all the judges of the criminal courts in the city, on the nomination of the coroner, a qualified officer, either for a specified term or during good behavior; with two deputies holding their positions by like authority and for a like term. Very possibly some other mode of selection might be suggested, but it seems to us as if this would be highly appropriate, since it would place the appointment in the hands of those with whom the duties to be discharged would bring the incumbent into most constant contact, and by whom his efficiency and faithfulness could be best appreciated.

The community has now no guarantee that in case of any circumstances depriving them of the valuable services of Dr. Shapleigh, his successor might not be either ignorant, negligent, or venal; and a very slight consideration only is needful to perceive that in such case most important interests of public or private justice might suffer. We therefore urge that a law or ordinance ought to be passed, providing for the regular appointment of a surgeon, with one or more deputies, and suitably prescribed fees, to aid the coroner in his special department.

The other duty is that of medical attendance in police cases. As the matter now stands, physicians are called upon by the mere chance of neighborhood, and with a very slim chance of payment, to afford what services are needed at the police stations, or in cases which come under police notice. We submit that here, as in London, Paris, New York, and many other large cities, there should be a regularly appointed board of Police Surgeons, whose term of service, duties, and fees should be prescribed by law.

It would not need any long course of argument to show how greatly the interests of the public would be secured by such an arrangement; while we could easily adduce cases in point to prove that they now suffer. The fearful state of things shown up in the daily papers a week or two since as existing at the "sub-station" in one of the worst and most thickly-populated sections of the city, could scarcely have been possible with medical sanction.

For the present, we shall be content with merely calling attention to these matters, hoping that they may be taken up and discussed until some deliberate and well-considered action may be the result, to the greater security of public and private interests.

JEFFERSON COLLEGE HOSPITAL.

THIS enterprise, rendered a necessity by the change which has come over medical teaching in this country, has been in effect placed by the trustees of the college in the hands of the Alumni Association. It is as yet but in its infancy, but the vigor and determination of its friends will insure its rapid growth and the thorough development of all its capacities.

We cannot better give our readers an idea of the present status of this project than by laying before

them an extract from the minutes of a meeting of the Alumni Association, held December 17; for which we are indebted to the Secretary, Dr. Mears:

"The committee suggested as a plan of organization —first, the collection of subscriptions contingent upon the raising of $250,000 by private subscription by the 10th of June, 1874, for the purchase of a new site, and for the erection thereon of a new College and College Hospital building, and for the support of the latter; second, an appeal to the State Legislature for an endowment of at least $100,000 for said hospital, such appeal to be made in connection with the Trustees and Faculty; third, the private subscriptions, to be called —first, from the resident Alumni, second, from the Alumni throughout the country, third, from the city at large; and that a committee be appointed from the Association, exclusive of the Faculty, with power to act in conjunction with the committees to be appointed by the Trustees and Faculty.

"It was resolved, on motion of Dr. J. H. Brinton, that the Executive Committee be requested to take the necessary measures for the securing of a new site and the erection thereon of a new college, with a college hospital attached, and the means for the support of the latter.

"Dr. Gross made an address, urging the need for increased accommodations, so as to form a museum, library, have chemical manipulations, a hospital with from fifty to seventy-five beds, etc., to secure which a large amount of money would be needed. He stated that they did not intend to move the college across the river, and believed they would have an increased number of cases by not doing so. The college was to have a future, which future depended on the action of the Alumni. No other college could boast of such prosperity as it has had in so short a time."

PROCEEDINGS OF SOCIETIES.

MEDICAL SOCIETY OF THE COUNTY OF ALBANY, NEW YORK.

ANNUAL MEETING, NOVEMBER 12, 1872.

Reported by JAMES S. BAILEY, M.D.

DR. JOSEPH LEWI, PRESIDENT, in the chair.

THE Treasurer, Dr. D. V. O'Leary, read his report, and announced that the Society was out of debt, and with a surplus of funds on hand.

The Chairman of the Board of Censors, Dr. James P. Boyd, reported favorably upon the admission as members of Drs. R. H. Starkweather, John H. Lagrange, and Gilbert H. Uhlman. They were elected members.

The President's address being next in order, Dr. Joseph Lewi then delivered the following upon

IDIOPATHIC PERITONITIS.

The variety of cases of peritonitis, as well as the many different causes by which this malady is contracted, make it very laborious for authors to dwell in detail on each; and while the student is allowed to profit in general knowledge by reading the lengthy articles about peritonitis, he does not derive the necessary information for the management of his cases.

And very naturally so. In most of the cases, peritonitis is the result of a traumatic injury, and the surgical as well as the medical treatment must depend upon the extent of the injury done to the peritoneum and adjoining parts. In other instances, peritonitis is due to effusion of the contents of an abscess into the cavity of the abdomen, or it is the result of a strangulated hernia, in all of which cases the treatment of the peritonitis will be subordinate to the general surgical treatment.

Peritonitis propagated from inflammations of other adjoining organs—stomach, liver, spleen, intestine—are considered and treated as secondary.

To puerperal peritonitis authors devote deservedly particular attention, on account of the frequency of cases, of the virulence of its character, and the great mortality resulting from it at certain times in certain localities. The above-named kinds of peritonitis are especially favored by the different authors of the present time with minute description of the nature, the symptoms, and the treatment of the same, leaving for the *idiopathic*, or, as some call it, the rheumatic peritonitis, only a little space, under the idea that this malady, contracted by a cold, is very rare and hardly ever attacks persons in general good health.

Although this last-mentioned kind of peritonitis is not so frequent as inflammations of other fibrous membranes, especially the pleura, I venture to maintain that peritonitis, especially in childhood, say from two to fifteen years of age, is of more frequent occurrence than pericarditis, and, from causes to be stated, more fatal than pleurisy. I will also state here that a twenty-six years' practice has taught me that this malady presents to a young practitioner more difficulties in forming a diagnosis and adopting a mode of treatment, and more embarrassment in giving satisfaction as to the prognosis, than any other inflammation. I therefore propose to say in this address a few words on *idiopathic* peritonitis.

Sometimes there are no premonitory symptoms; but in most of the cases a chill, slight or violent, will compel the otherwise well-appearing individual to retire from his avocation. After six or twelve hours the inflammation will, in very distinct cases, manifest itself by an intense fever, frequency of the pulse, high temperature, and a more or less violent pain in one or the other side of the abdomen, which side or spot will be very sensitive to the touch, so much so that the pressure of the bed-covers will be intolerable; the patient lying immovably on his back, his lower extremities drawn up. The patient talks little, and in a low tone. After a shorter or longer period the abdomen becomes bloated and filled with gas, which crowds against the diaphragm to such an extent that the lungs are compressed and impeded in their action. Respiration becomes difficult and frequent. Constipation and vomiting most generally accompany these symptoms of ante-peritonitis. In fatal cases all these symptoms increase in intensity, the abdomen becomes hard and tympanitic, the lungs and heart become so compressed that the respiration is very laborious, and the agony of the patient is terrible. At last he becomes apathetic and delirious, the pulse grows smaller and more frequent, the skin is covered with a cold sweat, and the patient dies. In a great many cases the disease does not reach such a desperate height. The symptoms having culminated, the intolerable pains and difficulty of breathing grow gradually less and less severe, and the patient recovers after the lapse of a few days or weeks.

And in some instances, even after the malady has assumed all the bad features described above, it makes a retrograde movement; the symptoms come to a stand-

still, absorption of the infiltrated blood takes place, or an abscess forms, the contents of which either discharge through the walls of the abdomen by nature's effort or by surgical interference, or they penetrate into the adjoining rectum or bladder, whence they are expelled with the fæces or urine,—and the patient may recover entirely, or may be troubled temporarily, or for the remainder of his life, with the results of this extraordinary termination of the disease.

So far the regular process of cases of idiopathic peritonitis, as described by most authors and known to all practitioners.

The management of such cases of peritonitis was, as late as twenty-five years ago, strongly antiphlogistic. Blood-letting by venesection and the application of leeches, mercurial preparations internally and externally, scanty nourishment, and the mildest of drinks in the inflammatory stage, absorbents internally and blisters externally in the stage of exudation,—such has been the treatment prescribed by the authors of former times. This plan has now been almost universally abandoned as irrational and pernicious, and, although it has been demonstrated that by promoting the peristaltic motion of the bowels the symptoms of inflammation will become aggravated, and the inflammation extend, and that the loss of blood (by venesection or leeches) will add so much to the general debility resulting from the disease itself, as to destroy the energy of the constitution of the patient so essential to reaction, and although we must admit that vast numbers of the human race have suffered an untimely death by this course, my long experience and close observation compel me to say here that there are exceptional cases of peritonitis where the application of leeches, and even venesection, is not only permitted, but imperatively demanded to save the life in some instances, and to bring on a speedier recovery in others. If a person extraordinary in development and plethoric in appearance is, after exposure, etc., seized with all the above-described abdominal symptoms to such a degree as to bring, within twenty-four hours, his pulse to 120 or 130, the temperature to 103°, and the respiration to 40 or 50; if delirium and a cyanotic appearance of the face should accompany these symptoms, a practitioner is, in my opinion, not only justified, but morally obliged to resort to blood-letting. I have seen in a large number of cases the most beneficial results from it.

The circulation and respiration improved so much that the inflammation took its natural course and was in time conquered by less heroic means; and it is to be presumed that in a majority of these cases the violent onset would have destroyed the patient before the disease had fairly developed, and before any other measure could have made any impression on the system thus disturbed.

But, with the exception of blood-letting in such exceptional cases, and counter-irritants in the later stages of the disease, all the appliances belonging to the antiphlogistic and depleting mode of treatment ought to be relinquished for all time to come.

In a great many, and, as my experience tells me, in a majority of cases of idiopathic peritonitis, the course is irregular, and therefore not easily to be distinguished from other complaints of the abdomen; and if the practitioner does not take heed, and is over-hasty in forming a diagnosis, the patient's life may be endangered, and with it the reputation of the physician.

In such cases the patient becomes indisposed and morose, loses his appetite, and complains occasionally of a dull, annoying pain in the abdomen. Aversion to all kinds of solid food, and an inclination to vomit, satisfy him or his neighbor that his "stomach is out of order," and a "good, strong physic" is taken on his own judgment, or on the advice of somebody. The remedy so taken generally distresses the patient more or less; he tries, and after awhile succeeds in throwing up the same, with whatever eatables were contained in the stomach, with a good portion of bile. After being relieved of the distress, but exhausted from the exertion of vomiting, the patient imagines that he feels better; but soon after he complains again about the pain all over the abdomen; and at this stage only, even in better classes of society, the physician is sent for. The patient explains to the doctor that "he is not sick; that his stomach was only out of order for the last few days; that he was constipated; that the physic he took seems not to have been strong enough for his constitution; that he vomited the medicine as well as bile, and that a strong laxative to remove the bile would probably be the best for his case."

The physician examines the patient, and ascertains that there is a circumscribed space on the abdomen painful to the touch; that there is no expansion of the abdomen, no tympanites, no fever; all the symptoms of the digestive organs correspond to the narrative of the patient, and he is very apt to act according to the suggestion of his patient, and to aggravate the case most decidedly. If the proper course is adopted, the patient will have the benefit of temporary relief under all circumstances, and, if it turns out to be a mild case, may recover within a few days. If it is a bad case, the symptoms will develop in the course of a day or two, so as not to leave any doubt in the mind of the physician about the nature of the disease and the necessary remedies, and then it will be time to adopt a mode of treatment in accordance with the suggestions of the modern authors. However difficult it may be in the primitive stage of all such cases of semi-acute peritonitis to make a correct diagnosis, and however often the practitioner may become guilty of misconception and the introduction of improper treatment through the interference of the ignorant patient, it is far more difficult to avoid mistakes in similar cases of children under six years of age. Compared with other disturbances of the abdominal part of the body, peritonitis is of such rare occurrence that the parents or guardians, in most cases, resort either to laxatives in the form of castor-oil or rhubarb, or to very drastic vermifuges, and before the physician is called all the mischief is done and the case is desperate. The slight local pain has changed into a violent, excruciating one all over the abdomen. The physic given has not evacuated the bowels, but has caused them to swell up and to be sensitive to the touch. Insatiable thirst, high fever, and a tendency to vomit, are the results of the harmless medicine given yesterday. The physician, if not ripe in experience, is liable to misconception, where the history of the case is given to him by a talkative mother, who prejudices his opinion of the case; and where the general as well as the local symptoms of the inflammation are so indistinct as described above, he is the more liable to make a mistake as the patient is not sensible enough to describe his condition, correct the misstatements about the course and duration of his complaint, and, in his peevish condition, not inclined to answer questions. Misled in this primitive stage of the disease, and induced to administer purgatives, the physician will only find out his mistake when it is too late to correct it, and when, in consequence of his injudicious interference, the symptoms have assumed such a character as to make the prognosis very unfavorable. To avoid the commission of such mistakes in similar cases, I would advise all young and inexperienced practitioners to take the utmost pains in making the examination; to be reserved in expressing a decided opinion at their first and second call; to adopt an expectant course, and to use only such palliative

remedies as will be beneficial to the patient; and to avoid all measures that could in any event have a tendency to promote the peristaltic motion of the bowels or to irritate the serous membranes of the abdomen.

Warm applications in the form of wet flannel or poultices, small doses of opiates in the form of Dover's powder or a solution of morphia, mild drinks, a horizontal position, and positive rest, will, in most of the cases, accomplish a cure and speedy recovery. In some cases the disease may assume a chronic course and require absorbents, counter-irritants, and tonics; in other instances the above-described semi-acute inflammation may after a few days develop into a very violent acute inflammation, and require a more heroic treatment.

But, under all circumstances, even if the diagnosis should turn out to be incorrect, and the patient should suffer from colic or worm-fever, or the painful spot should develop into a muscular abscess, no harm will have been done and no aggravation of the symptoms caused by the mode of treatment adopted.

In all cases of suspected peritonitis where the symptoms are not distinct and conclusive, the physician should call to mind all the diseases that could be mistaken for peritonitis. Catamenial colic, uterine colic, hysterical pain in females, pains from indigestion, bilious colic, nervous colic, inflammation of the duodenum, of the stomach, or of the liver, enteritis, retention of urine, worms, and wind-colic, present in some instances symptoms similar to those described in semi-acute peritonitis. The physician may ascertain the nature of the disturbance by closely examining whether his female patient is at or near the period of menstruation, or whether she is pregnant; he may also be able to determine in a great many of these obscure cases that the tenderness and pain indicating peritonitis are dependent upon the irregular functions of some disordered digestive organ, or the presence of worms or gas in the intestines, and proceed energetically to relieve the patient at once; but if there remains a shadow of doubt in his mind about the existence of an inflammatory process in the peritoneum, he must content himself with the administration of such remedies and appliances as to relieve the patient of pain and distress, to give him the necessary rest and comfort, and to keep his strength and vigor intact for the expected struggle.

Now, gentlemen, let me congratulate you on the happy termination of another year of the Society's existence and prosperity; let me thank you in the highest terms for the support given me, for the numerous attendance at the meetings, for the interesting contributions and instructive debates, as well as for the peace and harmony maintained during the last year's administration. Allow me, gentlemen, also to draw your attention to the memory of one who has been associated with this Society for more than half a century, who has been a useful and efficient member of this as well as the State Medical Society, and who departed this life, after having labored faithfully in the profession that he loved so well for more than fifty years, ripe in years and honored by the profession as well as the community. I allude to our brother the late Dr. Peter Van Olinda; and, while we deplore his loss, it is a matter of congratulation that this is the only loss by death our Society, numbering one hundred and fifteen members, has sustained; and he almost an octogenarian. You have this year admitted fifteen new members,—the largest number during one year since the existence of the Society.

The Society then elected the following named officers, viz.,—

President,—Dr. Albert Van Derveer.
Vice-President,—Dr. A. W. Shiland.
Secretary,—Dr. F. C. Curtis.
Treasurer,—Dr. William H. Murray.
Censors,—Drs. J. P. Boyd, S. H. Freeman, J. N. Northrop, P. P. Staats, C. E. Whitbeck.
Delegates to the State Medical Society,—Drs. Charles A. Robertson, Henry March, Amos Fowler, Daniel V. O'Leary.

PHILADELPHIA COUNTY MEDICAL SOCIETY.

Dr. J. G. Stetler, Vice-President, in the chair.

At a conversational meeting held November 13, 1872, at 8 o'clock P.M.,

Dr. Washington L. Atlee reported the following case. On the 23d of last September he was called to see a lady, 63 years of age, who came to the city from the interior of the State. Previously she never had any disease, and she had no hereditary taint or morbid diathesis of any kind. During the past winter she took cold easily, and complained of general malaise. Early in March last the left side of her throat became affected, the submaxillary gland on the left side enlarged. Tumors then formed in both axillæ, in the parotid regions, and in the groins.

When he saw her first, on the date above mentioned, she was in a cachectic condition, could not articulate, and deglutition and breathing were difficult. The tumor on the left side extended from the external ear to the shoulder; on the right side the tumor was only one-half this size. The sublingual and submaxillary regions were both enlarged. The axillæ were so filled up that the arms stood out from the body a considerable distance. The upper and lower extremities were œdematous. The mouth was filled with a tumor from its middle back into the pharynx, thrusting forward the soft palate, so as to make it become the anterior and upper wall of the tumor, interfering with respiration, deglutition, and speech.

She came to me, thinking to have it extirpated. On the surface projecting beneath the soft palate there was an ulceration the size of a silver half-dollar. These tumors were so hard and immovable that, had it not been for their general distribution, Dr. A. would have considered the disease to be scirrhous cancer. An isolated tumor of such a character, occurring at this age, and accompanied by such decided cachexia, he would not hesitate to pronounce malignant. The growth had been exceedingly rapid; and different modes of treatment, including electrolysis, had been tried, without any improvement. Hesitating to call it malignant, he had given an unsatisfactory diagnosis and a very unfavorable prognosis; but to-day the patient is well, the tumors having disappeared almost entirely. The treatment had been simply three drops of Fowler's solution and ten grains of the muriate of ammonia three times a day, with a locally-applied solution of muriate of ammonia.

Dr. Atkinson spoke of a case in the person of a woman with a child six months old. He had first seen her three months ago, and had been attending her at the Howard Hospital. He considered the trouble to be an ovarian tumor, and had been prescribing ten grains of the muriate of ammonia three times a day. On this statement of Dr. Atlee, he would continue it, with the addition of three drops of Fowler's solution three times a day.

Dr. O'Hara asked if these swellings were not adenoid enlargements from chronic adenitis. He recalled a case in which there were persistent tumors on both sides of the neck, resembling, on a small scale, Dr. Atlee's case, in which arsenic, iron, and iodide of potassium had been used for months, but which now

seems to be improving under iodide of mercury and cod-liver oil.

He also mentioned, in connection with the subject of arsenic, that, owing perhaps to idiosyncrasy, arsenic at times, like mercury, can be exhibited and continued in almost enormous amounts. One of his patients has taken arsenic for twenty years, at intervals, at his own discretion, for psoriasis. To his knowledge he has taken one-tenth of a grain three times a day for six months, always with benefit to the skin-affection and with no apparent ill effects. He asked whether any gentleman had used decolorized tincture of iodine externally. By the addition of hyposulphites to the tincture it can be made transparent, and its external application would not stain the skin. He also added that he had seen a case of epithelial cancer of the vagina, pronounced such by himself and an eminent professor, which seemed to be cured by arsenic and the local application of iodine and the permanganates. This patient subsequently bore a child, and locally there is no trace of the disease.

Dr. ATLEE said that his case was neither one of adenitis nor of parotitis, as the tumors were not sensitive and the patient complained of no pain. Neither was it scrofulous, as scrofula could not be first developed at such an advanced age, nor would it yield so readily to treatment. Neither could he regard the disease as adenoma. He did not know what it was, and desired to be informed by some of the experienced gentlemen present. He would have called the disease scirrhous cancer, had it not been so generally distributed through the system. The contents of the tumor were not microscopically examined. He believed that the cancer-cell could be kept from forming by using arsenic in small doses and keeping the patient under its tonic and alterative action, avoiding its specific influence on the system, as well as gastric irritation, and continuing it for a long time,—one, two, or three years.

Dr. W. M. WELCH asked whether it was not possible for this tumor to have been an enlarged lymphatic gland, deeply seated, pressing forward internally.

Dr. ATLEE said the tumors were entirely distinct and somewhat nodulated.

He also stated that her sister, who is two or three years older, has goitre. For goitre he always uses the officinal tincture of iodine, ten drops three times a day, together with its external application. He has never found this to fail, but has had to continue the treatment one, two, or three years. With regard to arsenic, he wished to be distinctly understood; he does not believe that it will cure cancer. If, however, the cancerous growth be removed, which he believes in many cases to be a local disease, then it is that arsenic will show its remedial power. It will extinguish, he believes, the tendency to cancerous formation in that part or in any other. It will not produce absorption of cancerous material, but simply prevents its development. In several instances of cancer of the breast, after amputation, he has seen, under this treatment, the patients remaining well from five to twenty-five years. In one case of carcinoma uteri which had been pronounced incurable by Profs. Meigs and Gilbert, he had applied to the diseased surface every four days the following:

℞ Iodinii, ʒj;
Potass. iodidi, ʒj;
Glycerinæ, fʒij;

while internally arsenic was administered. This patient was treated several years ago, and is now well. She is over fifty years of age. Similar cases have been treated in their incipient stage with like results. He referred to another case, that of the wife of a physician of this city, in whom the cancerous growth involved the lower portion of the cervix and os, the vaginal fold surrounding the neck not being invaded. She was in a cachectic condition, with anæmia from repeated hemorrhages. The diseased cervix was removed several months ago, and the arsenical treatment adopted. The parts are now in a healthy condition, and the patient goes out daily. The arsenical treatment will be continued for a year or two. If there is no deposit upon the vaginal wall, he would recommend the removal of the os and cervix, even though there was a possibility of some diseased tissue remaining above the point amputated. The patient will recover from the operation, her life be prolonged, and her health much improved; but the disease will again return at some future time.

Dr. W. H. PANCOAST stated that he had witnessed the use of condurango in the case of a gentleman affected with an encephaloid cancer of his upper jaw.

He was called in too late to perform any operation for the removal of the diseased part, and could only recommend cleansing applications, together with a supporting and soothing treatment. The patient finally died of exhaustion. He had been taking, upon his own responsibility, without any benefit, a wineglassful of the fluid extract of condurango three times a day for more than six months.

GLEANINGS FROM OUR EXCHANGES.

ON THE FALL OF TEMPERATURE ACCOMPANYING GREAT WOUNDS BY FIRE-ARMS (By Paul Redard: abridged from a Translation by Arthur E. J. Barker, L.R.C.S.I., *Dublin Jour. of Med. Science*, Sept., 1872).—Though increase of the temperature of the body above the standard of health has attracted so much attention, the reverse phenomenon has not been sufficiently studied. Brown-Séquard, however, has shown that when in illness, or after wounds or poisoning, the temperature falls a certain number of degrees, there is danger of death solely as a consequence of the fall.

Long-continued exhausting discharges, want of sufficient nourishment, and hemorrhage, have been observed to produce this fall of temperature; but in a more marked manner has it been seen to follow extensive burns, and to occur in uræmia, in sudden ammonia blood-poisoning, in certain cases of septicæmia, sometimes in chronic peritonitis, in internal strangulations and wounds of the intestines (Demarquay), immediately after apoplectic seizures (Charcot), generally in lesions of the spinal cord and in compression of the brain, as in hydrocephalus. Hirtz gives as a pathognomonic sign of tuberculous meningitis a fall of temperature coming on at the prodromic period of the malady. A fall of temperature has also been observed after the termination of fever, pneumonia, etc. (the defervescence of Traube), and in various maladies which impede the circulatory and respiratory functions. The administration of digitalis and of tartar emetic has the same effect; alcohol as a veritable retarder of molecular interchange causes frequently a considerable fall of temperature: in the acute stage of drunkenness M. Redard has often observed a temperature of 36° (96° 8′ Fahrenheit).

Placed during the latter period of the French war,—the struggle between the regular army and the Federals,—in the ambulances "*de la Presse*" (in the service of his master, M. Demarquay), M. Redard had ample opportunities of noticing the effect of injuries by fire-arms in lowering the temperature. Every time a patient suffering from a grave wound from a fire-arm was observed by him, a lowering of the temperature of the body was found. In most of the cases the injuries had been inflicted by the bursting of shells, but in some they had been caused by cannon-balls shattering limbs,

and in the instances of the Federals the wounds had usually been received while they were in a state of intoxication. In such M. Redard found a wound produced a much greater fall of temperature than did one of equal extent in men of temperate habits, and in them amputations were most unsuccessful. He, therefore, quite endorses the dictum of M. Verneuil, that the prognosis of traumatic lesions, all other things being equal, presents an exceptional gravity among subjects addicted to drinking chronically. The author narrates his observations in fifty cases, and concludes his memoir with the following deductions:

"1. In great injuries by fire-arms, fall of temperature is a constantly observed fact.

"2. Several elements come into play in producing this fall. Among the principal we will mention,—nervous shock, the excitement of the combat, with consecutive stupor, hemorrhage, and, lastly, alcoholism.

"3. Every wounded man brought into an ambulance with a grave wound, which seems to necessitate an operation, and who shows a temperature below 35° 5′ (95.9° Fahr.), will die, and ought not, consequently, to be operated on.

"4. Every wounded man in whom a salutary reaction is not produced within four hours, and in whom the reaction is not a direct sequence of the fall of temperature, must be considered as very gravely injured.

"5. Burns give rise to an exceptionally great fall of temperature.

"6. The same is the case in wounds of the abdomen. The fall is the more marked the nearer the wound approaches the stomach.

"7. The diagnosis of penetrating wounds may become less difficult, on account of the characteristic thermometric phenomena to which they give rise.

"8. The state of intoxication in which the wounded are sometimes found favors singularly the observed fall of temperature.

"9. Wounds by shells, all other things being equal, produce a fall of temperature more accentuated than those by balls."

Case of Gastrotomy (By Francis Troup, M.D., Auchtermuchty: *Edin. Med. Jour.*, July, 1872).—In the year 1867, a man, æt. 50, asked my advice about loss of appetite, and gnawing pain at the epigastrium after taking food. This pain had troubled him more or less for a year, and now vomiting of bloody-looking fluid containing particles of food had set in. No treatment relieved these symptoms; the quantity of food rejected increased; blood was brought up in small nodules, like "boiled liver," as patient described it; and the act of swallowing was slowly performed, and excited a peculiar suffocative cough.

No tumor could be felt, but a bougie passed down the œsophagus encountered a constriction at lower third of sternum; when this was passed, a second, an inch or so lower; and then it found free entrance into the stomach.

During many months, nine at least, attempts were made to keep the passage open by bougies, the patient himself learning to introduce them; then, as increasing difficulty of passing them was experienced, elastic catheters of gradually-diminishing calibre were tried, and a certain amount of food introduced in this way. Nutrient enemata were also freely used. By-and-by the canal became completely closed, and there was constant hawking and coughing up of clear, tenacious, ropy mucus, and for a month before death patient was almost entirely supported by the enemata. During the first part of this month patient complained much of hunger; during the last fortnight, only of a thirst which was something dreadful to bear. He was anxious to live if possible, or, at all events, to have something done to relieve this tormenting thirst. I carefully explained to him that it was possible to open the stomach and to introduce nourishment; that so doing could not possibly cure him, and might prove speedily fatal; but if he survived, I believed his thirst would cease. He elected to have the operation done; and, assisted by the late Dr. David Lyell, of Newburgh, who gave chloroform, and his father, Dr. John Lyell, now of Glasgow, I proceeded to do it in the following manner: A straight incision, three inches long, commencing a little below the extremity of the xiphoid cartilage, was made to the left of the middle line of the abdomen, and midway between it and the costal cartilages. The thin abdominal walls and peritoneum were easily cut through, and, guided by the liver edge, search was made for the stomach,—a somewhat difficult matter, owing to the tenseness of the abdominal parietes, and the shrunken condition of the viscus itself. Pulled down and firmly held by forceps, an opening into it was made, its edges stitched to the parietal incision, and a tracheotomy-tube of moderate size, and with a large shield, secured in the wound. Milk, in gradually increasing doses, and stimulants, were now easily passed into the stomach, and the three remaining days of the man's life were spent in comparative comfort.

The operation scarcely raised the pulse, and the patient repeatedly expressed the opinion that it was worth while having undergone it, were it for no other thing than the quenching of his thirst. A post-mortem was with difficulty obtained. The cardiac end of the œsophagus was found converted into an epitheliomatous mass, through which, even with the assistance of daylight, no passage could be found. The stomach was very small, and had been struck about its middle. The opposed serous surfaces of stomach and parietal incision were in parts adherent, and the incision itself, in all its length, healing. The peritoneum had not inflamed,—a sufficiently remarkable fact, considering the free handling to which it had been subjected.

Colotomy for Intestinal Obstruction (*Medical Times and Gazette*, Aug. 24, 1872).—Mr. Steele commences by observing that many cases of intestinal obstruction terminate fatally without surgical interference, which, were timely operative measures adopted, would very probably end in recovery. He relates the case of a man, aged 52, who, usually enjoying good health, had lately suffered from diarrhœa. On June 2 he was unable to relieve his bowels; he took castor oil, but without effect. Mr Steele saw him early next day, and found tympanites, colicky pains, and fæcal accumulation in the rectum, with strong desire for defecation. Various aperients and enemata were unavailing; the rectum was cleared out, and galvanism was applied, but without result. Bad symptoms soon set in, succeeded by failing power of the heart. This was relieved by ether and laudanum. Liquid food was well taken and retained. On the sixth day, the patient, who had somewhat rallied, suddenly becoming worse, colotomy was performed. Flatus immediately escaped, and fæces some few hours afterwards. Localized peritonitis, inflammation of the skin, diarrhœa, gastric and intestinal irritation, etc., gave great anxiety for about four weeks. By this time the wound was well healed round the intestine, and the patient improved, and became restored to fair health, but remained weak. No passage per rectum had since occurred; but free discharges of thick mucus had proved troublesome. A swelling high up in the pelvis, which before operation seemed like fæces accumulated in the intestinal coils, afterwards descended, and proved to be a tumor, and the cause of obstruction. The patient was doing well. Mr. Steele concludes with observing that where the cause of obstruction is obscure, and appears to be fæcal

accumulation, all legitimate endeavors should be made to dislodge the same; that when the cause of obstruction is clearly mechanical, opiate treatment should be immediately commenced, and operative interference promptly adopted; that in such a case as the one narrated, surgical aid is the only means of saving life; that a person with a tumor compressing the lower bowel is in a much better condition with an artificial anus than with a constantly forced passage by the natural orifice; that the growth of the tumor will not be nearly so rapid as if it were subject to compression by the fæces and strained defecation; and that operation is most likely to be successful when the obstruction is caused by tumor, there not being sloughing to fear, as in internal hernia, or intussusception.

Effects of Quinine upon the Uterus.—Dr. F. K. Bailey, of Knoxville, Tenn. (*Medical and Surgical Reporter*, Nov. 9, 1872), gives the result of his experience in a malarious district:

"It was very common to find a pregnant woman suffering from uterine pain during a fit of ague, and abortion or premature labor often occurred in cases where timely antiperiodic treatment could not be carried out. In all such cases it was my practice, as well as that of others, to administer quinine promptly and freely. There was no other way to carry a patient over such a period of danger, except to suspend the periodical tendency.

"Again, the question is often asked, Is quinine admissible or ever indicated during labor, to regulate the expulsive efforts of the uterus? In answer to this I can say that in very many instances during labor occurring in the summer or autumnal months I have given quinine with the most happy effects. It was often the case that natural labor at term was ushered in by a chill, and the depressing effects of malaria would render the pains feeble and without expulsive power. At this juncture a full dose of quinine would equalize the circulation and render contractions more forcible."

MISCELLANY.

The *Clinic* of December 7 says that the Prussian government has issued a circular requesting that investigations may be made by the district medical officers on the duration of the incubation of cholera, and the means by which infection is conveyed,—whether by soiled linen, clothing, rags, textures of any kind, skins of animals, animal and vegetable articles of food, etc. If it be answered in the affirmative that any of these convey cholera, it is further asked how long the contagion retains its activity. Four cases of cholera were reported last week to have occurred in Vienna. One of the patients only, a man aged 27, admitted into the General Hospital, was found to have true cholera; the other three were cases of gastro-intestinal catarrh, connected in one instance with psoas abscess. It has been decided to provide a number of cholera-hospitals around Vienna. The *Allgemeine Wien. Med. Zeitung* states that from October 18 to November 3 there were 129 cases of cholera in Buda, with 29 deaths; during the same period one case occurred in the adjoining city of Pesth. Active measures are being carried out in both these places to meet the epidemic. The Hungarian Minister of the Interior, Herr Tóth, has occupied several days in personally visiting the hospitals, prisons, schools, barracks, hotels, and other public buildings in Pesth, in order especially to see that disinfection is carried out, and has sent to the public papers reports expressing, according to the state of the case, his satisfaction or dissatisfaction. The cholera patients have been removed from the hospital at Buda into private houses and barracks.

Mr. Darwin's New Work.—Mr. Darwin's forthcoming work on *Expression in Man and Animals* bids fair (says *Nature*) to be of a more popular character than any of his other publications. It will commence with a statement of the general principle of Expression: that serviceable actions become habitual in association with certain states of the mind, and are performed, whether or not of service, in each particular case. This will be illustrated in the case of expression of the various emotions in man and the lower animals. The means of expression in animals will then be discussed, and the special expressions of animals and man, such as the depression of the corners of the mouth in grief, frowning, the firm closure of the mouth to express determination, gestures of contempt, the dilatation of the pupils from terror, the causes of blushing, etc. In conclusion, the bearing of the subject will be spoken of on the specific unity of the races of man; the part will be discussed which the will and intention have played in the acquirement of various expressions; and the question of their acquisition by the progenitors of man will be referred to. Seven heliotype plates, reproduced from photographs, will illustrate the work.

The Cholera in Europe (*British Medical Journal*, Nov. 23).—During the second half of October, 4477 new cases of cholera occurred in various districts of Austrian Galicia. There were also 1003 cases remaining under treatment on October 15, making in all 5480. Of these, 2909 recovered, 1677 died, and 894 remained under treatment. No cases of cholera occurred in Vienna or the immediate neighborhood during the week ending November 14. In Buda, the total number of cases of cholera from October 18 to November 14 (inclusive) was 535; of these 235 recovered, 181 died, and 119 remained under treatment. In Pesth there had been, up to November 15, 228 cases of cholera, with 41 recovered and 74 deaths. For the purpose of treating the disease, the latter city has been divided into two districts, to which fifteen physicians are appointed. Their residences are denoted in the daytime by flags, and at night by lanterns, so that the public may know where to make application. Sixty men have been appointed to see that cleanliness is maintained; they are stationed at twenty different points, at each of which three men watch in rotation.

Longevity.—The entries on the registers of deaths in England and Wales in the year 1870 represent that eighteen men and sixty-three women who died in that year had attained or passed the age of 100 years.

According to the registers, six men and twenty-two women were 100 years old; one man and fourteen women were 101; three men and eleven women were 102; two men and six women were 103; five men and seven women were 104; two women were 105; one woman, who died in Huddersfield district, was 107; and one man, who died in the district of Stone, Staffordshire, was 108 years old when he died. Of these centenarians, ten died in the metropolis, six in Somersetshire, five in Yorkshire, and four in each of the following counties, —viz., Cambridge, Durham, Glamorgan, Monmouth, Norfolk, and Pembroke.

New York Medico-Legal Society.—This Society held its fifth anniversary meeting, October 10, 1872, and the following officers were elected for the ensuing year: *President*, Clark Bell, Esq.; *First Vice-President*, John C. Peters, M.D.; *Second Vice-President*, Arthur J. Delaney, Esq.; *Recording Secretary*, James Ross, M.D.; *Assistant Recording Secretary*, William B. Wallace, Esq.; *Corresponding Secretary*, Jean F. Chauveau, M.D.; *Chemist*, Augustus Wohlfarth, M.D.; *Treasurer*, Thomas S. Bahan, M.D.; *Librarian*, William Shrady, Esq.; *Pathologist and Curator*, Philip E. Donlin, M.D.; *Trustees*, O. C. Warfield, Esq., T. C. Finnell, M.D., J. F. Miller, Esq., H. L. Richardson, M.D., Stephen Rogers, M.D.

That clerical and lay functions were once conjoined, the following old-time advertisement will sufficiently show: "Wanted, for a family who have had bad health, a sober, steady person in the capacity of doctor, surgeon, apothecary, and man-midwife. He must occasionally act as butler, and dress hair and wigs. He will be required sometimes to read prayers, and to preach a sermon every Sunday. A good salary will be given."

The days of charms and amulets are not yet past. Dr. V. Holsteck announces (*Bordeaux Médicale*) that he is invariably able to suspend the secretion of milk in the breast by suspending in front of the sternum a tube of goose-quill, sealed at both ends, but filled with metallic mercury. The secretion of milk is arrested in twenty-four hours; two hours afterwards the breasts resume their normal state.

Medical College of Ohio, Cincinnati.—The College museum has just received a valuable acquisition in the shape of the artistically prepared skeleton of "Old Man Dead," the College resurrectionist for the past forty years. The skeleton is seated on a tombstone, with spade in hand and pipe in mouth, in perfect self-complacency, apparently, over a recent successful "job."

The Elizabeth (N.J.) *Journal* says that a certain undertaker there sent to one of the prominent physicians of that place a lot of death-certificates with his card on them, as a complimentary present to the doctor. What the doctor sent to the undertaker as an acknowledgment of the compliment we have not heard.

London Items.—*The British Medical Journal* says, "We believe that Sir William Jenner will be nominated by the Council of the Pathological Society as President for the ensuing year; and Mr. Prescott Hewett will be nominated as the next President of the Clinical Society."

After nineteen years of devoted service, Dr. Sharpey is about to give place as Secretary of the Royal Society to Professor Huxley.

A Convalescent Home, which has been erected by the Pease family at a cost of upwards of £12,000, has been opened at Saltburn-by-the-Sea.

Mortality of Philadelphia.—The interments reported at the Health Office for the week ending Dec. 21, 1872, were 332; 192 adults, and 142 minors. 9 were of bodies brought from the country; making the mortality of the city 323. Among the causes of death were:

Consumption of the Lungs	37
Other Diseases of the Respiratory Organs	64
Diseases of the Circulatory Apparatus	19
Diseases of the Brain and Nervous System	60
Diseases of the Digestive Apparatus	11
Zymotic Diseases	17
Typhoid Fever	7
Casualties	11
Cancer	5
Suicide	1
Debility (including "Inanition" and "Marasmus")	32
Still-born	21
Old Age	18

(The interments reported for the week ending Dec. 23, 1871, were 539.)

The meteorological record kept at the Pennsylvania Hospital was as follows:

	Thermometer. Max.	Thermometer. Min.	Barometer. (2 P.M.)
Dec. 15	46.0°	34.0°	30.17 in.
" 16	38.0	31.0	30.18 in. (Rain.)
" 17	34.5	30.0	30.42 in.

OFFICIAL LIST

OF CHANGES OF STATIONS AND DUTIES OF OFFICERS OF THE MEDICAL DEPARTMENT U. S. ARMY, FROM DECEMBER 10, 1872, TO DECEMBER 16, 1872, INCLUSIVE.

Wirtz, H. R., Surgeon.—To accompany Battery "B," 2d Artillery, on 4th inst., to its station in the Department of the East, as Medical Officer, and on completion of this duty return to San Francisco, Cal. S. O. 223, Military Division of the Pacific, Dec. 2, 1872.

Hubbard, V. B., Assistant-Surgeon.—Telegraphic Order of 26th ult., from these Headquarters, directing him to report in person at these Headquarters for assignment to duty, confirmed. S. O. 191, Department of the Gulf, Dec. 8, 1872.

Delany, Alfred, Assistant-Surgeon.—Granted leave of absence for four months, with permission to apply for an extension of two months to go beyond sea. S. O. 323, War Department, A. G. O., December 11, 1872.

Munn, C. E., Assistant-Surgeon.—To report in person to the Commanding General, Department of the East, for assignment to duty. S. O. 319, War Department, A. G. O., Dec. 7, 1872.

Reynolds, Frank, Assistant-Surgeon.—Granted leave of absence for six months, on Surgeon's Certificate of Disability, with permission to go beyond sea. S. O. 323, c. s., War Department.

SATURDAY, JANUARY 4, 1873.

ORIGINAL LECTURES.

CLINICAL LECTURE
ON TWO CASES OF RENAL DISEASE.

BY DR. JAMES H. HUTCHINSON.

Delivered November 13, 1872.

Reported by DR. GEORGE S. GERHARD.

DR. HUTCHINSON began his lecture by reading the following notes:

Margaret K., aged 38, a native of Ireland, married, and mother of seven children, was admitted Nov. 5, 1872. She is free from any known hereditary taint, and until her present troubles began had always enjoyed good health. About five months before her admission she was taken suddenly with pain in the right lumbar region. It was intense at first, and caused her a great deal of suffering; it, however, gradually wore away, and in about a week disappeared entirely. About a fortnight afterwards the part previously the seat of pain became tender to the touch, and this led to the discovery, on the part of the patient, of the "lump" which now exists. She has never had rigors or sweats. She has been subject now and then to a "kind of stoppage" of urine, and this secretion has occasionally had a milky appearance. About three weeks before admission her feet and legs began to swell. The patient has never had menstrual difficulties; she is habitually costive. She is unable to say whether the tumor has increased in size since its discovery.

On admission it is noted that the patient is anæmic and sallow; her tongue is pale, and her bowels are sluggish. The abdomen is very prominent, and begins to rise abruptly about one inch above the umbilicus; its anterior wall is thin, and the peristaltic wave of the intestines is distinctly visible; the prominent part of the abdomen is clear on percussion.

In the right lumbar region a resistant body having obscure outlines can be felt; it is behind the intestines and is not connected with the liver. The posterior part of the right lumbar region is dull on percussion, and notably prominent. Neither the patient's movements nor the movements of respiration affect the position of the tumor.

The tumor, or as much of it as can be felt, has an even surface, and is not tender to the touch.

The area of hepatic dulness is not increased. The feet and legs of the patient are œdematous, and pit readily on pressure.

The pulse is feeble. Over the body of the heart a soft hæmic murmur is heard.

The patient states that she loses a considerable quantity of blood from hemorrhoids.

The urine is light-colored: its specific gravity is 1014, and it contains a large amount of albumen.

On the 12th the following note was made:

The patient has had a severe diarrhœa for several days past, but the size of the tumor remains the same.

She is to use suppositories of tannin and opium.

The temperatures which have been taken at various times since the patient's admission are always above the normal. These are the notes of the case up to the present time.

The patient, you see, is excessively sallow and anæmic, and you will notice when I draw down the lips how pale the mucous membrane is. I call particular attention to this point, because anæmia produces paleness of the mucous membranes sooner than of the skin.

As the notes have told you, there is a hæmic murmur heard at the base of the heart. These murmurs nearly always have their point of greatest intensity at the base of the heart, and at the second costal cartilage near its junction with the sternum.

There is a point worth knowing in connection with blood-murmurs; and it is that they are always heard with greater distinctness when the patient is in the recumbent posture.

The lower extremities of the patient, you notice, are œdematous and pit on pressure. There is no thoracic disease.

Now, in regard to the abdomen. And, first, let me give you some general directions for its exploration. The means we have for examining the chest are equally applicable to the abdomen, viz., inspection, palpation, percussion, auscultation, and mensuration. It would seem only natural that a perfectly flaccid wall like that of the abdomen should offer but slight resistance to the exploration of organs contained within; but in reality it is more difficult to detect abdominal disease than thoracic.

The patient, as the one before you, should be placed on her back, with her head slightly raised, and her thighs flexed upon the abdomen in order to relax the muscles as much as possible. You should take care that your hand is warm, and then, with the palm flattened, make uniform and gentle pressure.

The abdomen of the patient before you, as you have learned from the notes, rises abruptly about one inch above the umbilicus, and has its walls so attenuated that you can see the peristaltic movements of the intestines. It is everywhere resonant on percussion, and when pressure is made on the right side an obscurely defined resistant tumor can be felt occupying the back part of the lumbar region. It is, as the patient tells us, never painful, and is not tender on pressure. Neither the respiratory movements nor the movements of the patient herself affect its position.

What is the nature of this tumor, and with what organ is it connected?

The first organ suggested is the liver; but this occupies its normal position and does not extend below the costal border. Nor is there a possibility of its being connected with the ovary or uterus, because they would, when enlarged, occupy a position more anterior; and, besides, there is no history of either ovarian or uterine disease.

That the tumor is not due to impacted fæces is proved by the fact that the diarrhœa with which the patient has been suffering for several days past has not in the least degree affected its size.

Peri-nephritic abscess would give rise to swelling in the region of the kidney, but at the same time it would in all probability be associated with pain and tenderness on pressure.

We come, then, by a process of exclusion, to the kidney itself, which, you know, in its normal state

occupies a position far back in the lumbar region. It has been said in the notes that the patient has been the subject of urinary difficulties. The urine has had a milky appearance, and there has been at times what the patient terms a kind of stoppage of the secretion; but the latter was probably a reflex result.

I will now show you the patient's urine, and point out to you the ordinary tests for determining the presence or absence of albumen.

There are, as you know, two tests for the detection of albumen in the urine; but neither should be relied upon to the exclusion of the other. One consists in the application of heat to the urine; the other in the addition of nitric acid. It must be remembered that the phosphates are also thrown down by heat, and that uric acid is precipitated by nitric acid, but the urates are dissolved by heat, and the phosphates by nitric acid. It must also be remembered that albumen is soluble in urine to which too little nitric acid has been added, and that it is soluble in urine containing an excess of the acid. I will now pour a small quantity of the patient's urine into a test-tube, and determine its reaction, because albumen will not coagulate in an alkaline fluid. The litmus paper, you see, becomes red; the urine is therefore acid. It is best to apply heat, as I am now doing, to the top of the urine in the tube; the liquid below remains unchanged, and the precipitate can be readily detected. I shall add a few drops of nitric acid to the urine containing the precipitate you now see thrown down. The acid has no effect upon it, which shows that it is not composed of the phosphates.

I shall now pour a drachm of urine in a test-tube held in a slanting position, and add to it about fifteen drops of nitric acid, which, being of a greater specific gravity than the urine, will fall to the bottom. You see, at the junction of the two liquids, a well-marked, sharply-defined white ring, composed of coagulated albumen.

It struck me, when looking at the urine yesterday, that it contained pus. Since then the existence of this element has been determined by microscopical and chemical examination. Urine containing pus will become tenacious when agitated with an equal bulk of liquor potassæ in a test-tube. I will now add liquor potassæ to the urine in this test-tube. The liquid has become, you see, after shaking the tube a few times, very tenacious and ropy.

Now in regard to the nature of the tumor. Although the impression given to the hand is that of solidity, I do not, on account of the absence of pain and nodulation, believe in the existence of cancer. I am inclined to believe that the enlargement is due to purulent collection in the kidney, and that the commencement of the disease was an inflammation of the pelvis of the kidney, or pyelitis, originating, probably, in obstruction of the ureter.

Although the patient may live for some time, I think there is no question about a fatal termination. Her treatment consists mainly in the administration of tonics. She is taking iron, and gets the best food that the hospital affords.

The next case that I shall bring before you illustrates another form of renal disease, but one which, generally speaking, does not give rise to dropsy.

I shall first read you the notes of the case:

Mary K., aged 58, a widow, and native of Ireland, of intemperate habits, was admitted July 31, 1872. She has had five children, of whom all but one died in infancy. The one now living enjoys good health; is about 25 years of age. She states that her own health was always good until six years ago, when she was suddenly taken, while carrying a heavy weight, with spitting of blood. The amount of blood lost was sufficient to cause marked general prostration. Neither pulmonary nor abdominal symptoms followed, but she was under treatment five months, in one of the hospitals in this city, for what she terms "weakness."

She subsequently enjoyed good health until February, 1872, when she contracted pneumonia of the right lung, for which she was admitted into this hospital. She made a slow recovery, and for a long time there was harsh respiration at the upper part of the right lung, with some dulness on percussion.

It was noticed that the patient passed her urine frequently, but there is no record of its having contained albumen.

She was discharged from the ward June 4.

On the 31st of July she was readmitted. She stated that she suffered greatly from weakness, and that she had been obliged to abstain from work ever since her discharge in June.

On November 1, when the ward was handed over to Dr. Hutchinson, the following note of the patient's condition was taken:

The patient is very weak, and remains constantly in bed; her appetite is poor, and her stomach is irritable; the abdomen is full, but there is no evidence of effusion. The area of hepatic dulness is normal. She has a troublesome cough, accompanied by a muco-purulent expectoration. There is dulness on percussion under the right clavicle and in the right superior scapular region. In both of these regions moist, crackling sounds are heard on full inspiration.

She passes her urine frequently, and is obliged to get up several times at night.

The urine has a specific gravity of 1012; it contains a decided amount of albumen, and granular casts are seen under the microscope.

You see there is no evidence whatever of œdema of the lower extremities of this patient, and yet we have positive proof of renal disease, in the presence of albumen and casts in the urine. When I apply heat to this test-tube containing some of the patient's urine, a decided cloudiness is produced, which does not disappear when nitric acid is added.

As you have learned from the notes, the patient is troubled with frequency of micturition, and is obliged to get up several times at night. We have not been able to measure the quantity of urine voided in twenty-four hours, because it is occasionally passed involuntarily. This is important, because in certain diseases of the kidneys—acute nephritis, for instance—the quantity of urine is diminished.

In the form with which I think we have to do in the case before us, viz., the cirrhotic or contracted kidney, the quantity of urine is generally increased, but its solid elements diminished. In albuminoid degeneration the quantity of urine is also increased; but the history presented by the case before us, and

the kind of casts found, point, I think, to cirrhosis rather than to albuminoid degeneration.

As I have but a few minutes before the close of the hour, I shall occupy them in telling you of a case of sudden death from renal disease, that lately came under my observation.

One of the domestics of this institution went to bed on the night of the 7th, Thursday, feeling well, and having at no time presented symptoms of renal disease. Not making her appearance on Friday morning, an examination of her room was made, and the patient was found lying upon her bed in a condition of semi-coma.

I saw her on Saturday morning when she was sent to the ward. She was then completely comatose. She died on the following day.

Some of her urine was drawn off by the catheter, and was found to contain albumen and fatty casts. No autopsy was allowed; but I have no doubt that the patient had fatty kidneys, and that the coma depended upon uræmic poisoning.

[NOTE.—The patient, Margaret K., died on the 19th of December. Previous to her death, enlargement of the left kidney was also detected by palpation, and the probable existence of amyloid degeneration diagnosticated. The following are the notes taken at the post-mortem examination:

The body is much emaciated; the skin is generally sallow; the feet and legs are œdematous. The lungs are very pale, but in other respects are quite healthy.

The heart presents a healthy appearance. The liver is slightly increased in size; its tissue is firm, and presents an appearance of amyloid degeneration in an early stage. On microscopical examination the hepatic cells are found to be fatty; the spleen also is somewhat increased in size. The right kidney is much enlarged, and is tightly adherent to surrounding parts; its surface is not nodulated, and when pressure is made pus is squeezed from the ureter; it is resistant, and does not present any fluctuating point. On cutting open the organ, the pelvis is found distended with creamy pus.

Three calculi, the largest being of an irregular quadrilateral shape and measuring about an inch in its largest diameter, are found occupying the distended calices.

The proper substance of the kidney is entirely replaced by dense white fibrous tissue.

The ureter, as it approaches the hilus, is bound to the inner border of the kidney by bands of inflammatory origin; its canal is pervious.

The left kidney, very much enlarged, presents the macroscopical and microscopical appearances of amyloid degeneration.]

APHASIA FOLLOWING PARACENTESIS ABDOMINIS (*Le Mouvement Médicale;* from the *Union Médicale*, Sept. 24).—About six months ago, a woman aged 45 became almost suddenly aphasic in consequence of tapping for ascites dependent upon hepatic disease, performed by M. A. Guérin at the Hôtel-Dieu. After the liquid was drawn off, care was taken to make pressure on the belly at once, by means of a compress and bandage. Notwithstanding, the patient was seized, immediately after the operation, with complete aphasia, and with symptoms of hemiplegia on the right side. Her intelligence is now perfect, and speech has been restored to some extent; almost every sign of paralysis has disappeared from the lower extremity; the upper limb, on the contrary, is motionless, and the seat of a very marked contracture. The improvement already gained inspires the hope that the lesion is not wholly incurable.

ORIGINAL COMMUNICATIONS.

THE HORSE EPIDEMIC OF OCTOBER AND NOVEMBER, 1872.

BY ALBERT FRICKE, M.D.

With a statement of microscopical appearances of specimens, by Prof. JOSEPH LEIDY.

Read before the Biological and Microscopical Section of the Academy of Natural Sciences, Dec. 9, 1872.

UP to the present time only a few and mere casual observations have been published in our medical periodicals on the scourge which has now over five weeks decimated the horses of this city. From the first outbreak of the epidemic up to the present time I have carefully examined many cases during illness, and after death Drs. William Hunt, James J. Levick, and J. Koerper have kindly seen some of the cases with me. Prof. Joseph Leidy has been present at some of the post-mortems, and has, as well as myself, made microscopic examinations on the nasal discharges, blood, and such lesions as were found in the dead bodies.

One remarkable feature of this epidemic is the great rapidity with which it swept over the continent, appearing first in the far East, and in less than eight weeks reaching the sea-borders of Louisiana and Georgia; and it is still travelling West and South.

This rapid spread, and the first symptoms after the outbreak of the disorder, strongly resemble the well-known influenzas of the human family; in the progress of the disease this similarity seems to disappear. The coryza-influenzas of the human family have never shown great fatality, except by complications. In this horse epidemic the mortality is beyond precedent, and no one who has watched cases of this disease can deny the presence of a blood-poison far exceeding in virulence that which induces influenza.

The first symptom of this disease is a dry, troublesome cough, which, in grave cases, is ushered in with a chill and cold extremities, great depression of strength, a weak and somewhat accelerated pulse, and eyes slightly injected. Soon after, a light, colorless discharge from the nostrils appears; the cough continues without much increasing in violence, but the discharge from the nostrils becomes so copious that it runs like a stream from the nares whenever the animal lowers its head. This may continue for five or six days, and, if the case is a light one, and the animal is allowed proper rest and food, may pass into health again without any untoward symptoms, but not always. (See Case III.)

But if the case is a grave one, or the horse is now exposed to work and the inclemencies of the weather, the discharge from the nostrils increases, changes in color, becoming greenish-yellow, ropy, bloody, and fetid; the cough remains the same, or rather diminishes. The animal now generally refuses food, the respiration becomes labored, and, although the physical examination of the lungs shows

a healthy condition of those organs, the breathing assumes a truly spasmodic character, resembling closely the abdominal respiration of children in the last stage of croup; and the animal finally dies from exhaustion, refusing to lie down almost to the last moments of life. How different from the influenzas of our race! These have been the most striking features of all the cases coming under my observation, and which died in the first and second week of the disease,—twelve cases in all.

After the second, say during the middle or end of the third week, if the case progresses unfavorably, œdematous swellings make their appearance, sometimes to an enormous extent, the hair of the mane and tail falls out, the lining membrane of the nostrils becomes deep purple, the animals are very feeble, and but little hope remains for their recovery. How different from influenza! The mortality in this epidemic must have been very great; according to the estimate of Veterinary Surgeons M. W. Birch and James Marshall, both intelligent and reliable men, from one hundred and fifty to two hundred horses have died daily in this city, from the end of the first week—November 2—until now, November 27.

From my notes I will here relate some cases, and give the result of the post-mortem examination of each, and, later, add the communication of Prof. Leidy on the microscopical appearances of specimens.

Case I.—Horse of Mr. Miller; one of the first horses attacked in town. This horse showed at first no very grave symptoms; light cough, some discharge, fed well, and seemed in good spirits. It was driven out the second day; symptoms all aggravated; left off feeding; discharge from nostrils greenish, fetid, and bloody; difficulty in breathing; auscultation gave no indication of disease of lungs. Respiration finally became spasmodic and abdominal; died on the seventh day. Post-mortem made by Prof. Leidy and myself. The lining membrane of glottis, larynx, and trachea with the capillaries strongly injected and of a mahogany-red color. The whole surface seemed to be covered with a dark-green, bronze-colored paint. Lungs healthy.

Case II.—Mr. Edward Free's horse; sick eleven days; discharge from nostrils very copious, but not so fetid as in Case I. Breathing became daily more labored. Fearing that my auscultation in the previous case might have been inaccurate, I requested Dr. J. J. Levick, and afterwards Dr. William Hunt, to examine the animal. We could not detect anything abnormal. The horse died with the same truly distressing respiration as the first one. The autopsy gave precisely the same result. Deep bronze-colored mucous membrane, and injected capillaries of larynx and trachea; lungs healthy.

Case III.—Mr. Ramsey's pony; duration of sickness three weeks. This horse had hardly any cough or discharge from the nostrils, and fed well; was considered in the stable almost in normal health; was never exposed during its illness; suddenly, towards the third week its breathing became laborious, fetid, discharge from nostrils made its appearance, and it died apparently from exhaustion. Post-mortem made by Veterinary Surgeon Marshall and myself. Same result as in the former case.

Prof. J. Leidy and myself examined, at the skinner's yard, two or three horses which had died of this distemper. We found the same appearances in each. Glottis, larynx, and trachea with the capillaries injected and the mucous membrane of a dark-red and greenish-bronze color. Lungs and all the other viscera in a healthy condition.

I will here remark that not all cases show the green, bronze-colored condition of the mucous membrane, but always highly-injected capillaries, and, if the greenish color is absent, a dark mahogany-red one.

Case IV.—Mr. Saller's mare; duration of sickness somewhat over three weeks. This mare showed all the symptoms of nasal discharge, copious and discolored, but not bloody to any great extent. Respiration very laborious, and abdominal. Auscultation gave no abnormal result. Dr. William Hunt examined this mare several times with me, in the last days of her life. Auscultation showed strong mucous râles. Autopsy made by myself and Veterinary Surgeon Marshall. Same green, bronze-colored appearance of larynx and trachea, reaching deep into the larger bronchi. The whole lining membrane of trachea split at different parts in a longitudinal direction as soon as the trachea was opened. This was the first case where there was a fair appearance of exudation, or false membrane.

Case V.—Autopsy of horse which died at the Second and Third Streets Passenger Railway Company's stables; myself and Dr. W. Keller were present, by invitation of Veterinary Surgeon M. W. Birch. Same result as in the other cases. Took home part of larynx with glottis, and a piece of vomer with Schneiderian membrane; on all these parts were ulcerations. Duration of sickness six days.

Enough cases have now been related to show that this is a blood-disease, exhibiting well-marked anatomical characters in the mucous membrane of the nares, glottis, larynx, and trachea, either by stasis in the capillaries and exudation, or actually by the presence of that pathological product which we call false membrane.

Prof. J. Leidy's statement of microscopical appearance of specimens.

No. I.—Nasal discharge from Mr. Miller's horse; specimen thick, tenacious, and yellow. Beneath microscope (Hartnack No. 11 immersion) exhibited ordinary mucus- or pus-corpuscles, with usually a single and well-defined nucleus; also, multitudes of minute granules in short chains, straight and curved, constituting a form of vibrio not very active in movement.

A second specimen from the same horse, received a day or two later, showed the same character, but the vibrios appeared more broken up into their elementary particles.

Post-mortem examination of parts of the same horse at a later date.—The nasal, pharyngeal, laryngeal, and tracheal mucous membrane in a highly hyperæmic condition, dark mahogany-red, with a thin superficial stratum of a greenish-yellow hue, and numerous deeper minute spots, from the size of a pin-head to a line in diameter, of a still deeper red hue. The greenish layer was found to be the epithelium, and was composed of the ordinary ciliated columnar cells, with multitudes of other cells of various shapes, and without cilia, but with the same constitution.

No. II.—Nasal discharge from Mr. Free's horse;

same as in the preceding specimen, but with fewer vibrios in chains. Some dusky streaks exhibited spores of uredo, simple globular spores, mucor-threads, pollen-grains, and fragments of chaff.

No. III.—Nasal discharge from Mr. Bean's horse; same as in the preceding specimen. Dusky streaks also contained uredo-spores, round spores, germinating spores, and fragments of chaff.

No. IV.—Post-mortem examination of a horse at the skinner's. Mucous membrane in same condition as in the former case. Microscopic examination with the same result.

No. V.—Blood of a horse submitted by Dr. Fricke. Blood-corpuscles appeared normal. White corpuscles exceedingly few,—sometimes not one in three microscopic fields. This blood was remarkable for a great number of minute granules mingled with the blood-corpuscles.

No. VI.—Blood from another horse, submitted by Dr. Fricke, apparently normal. The blood-corpuscles arranged themselves rapidly in rolls in a much more striking manner than in the preceding specimen. White corpuscles few. Granules none.

No. VII.—Portion of the pharynx, larynx, and trachea of a horse submitted by Dr. Fricke. Mucous membrane of the same character as in the preceding cases. A patch of false membrane in the pharynx, in the vicinity of the laryngeal orifice, appeared like a superficial ulcer. The patch adhered tightly, and was of a gray color. On detaching it, it was found to replace the epithelium. The place beneath was bright red. The membrane consisted of large nucleated round granular cells, closely adherent one to another.

No. VIII.—Portion of nasal partition, pharynx, larynx, and trachea of a horse, examined at Dr. Fricke's residence. The mucous membrane of the parts as in previous cases, but upon that of the nasal partition, the pharynx, and larynx, there were large elevated gray patches of ulcers; they had well-defined borders, and the patches adhered tightly to the surface beneath. On removing the patches they were found to have rested in shallow, bright-red excavations of highly vascular connective tissue. The patches consisted mainly of large rounded granular protoplasmic masses or cells, more or less distinctly nucleated. Deeper parts contained shreds of a striated tissue, with multitudes of narrow spindle-shaped cells, apparently connective-tissue corpuscles.

So far Prof. J. Leidy.

Considering now the symptoms of the stated cases during illness and before death, the results of the post-mortem examinations, and those of the microscopic investigations of the lesions found in the nares, pharynx, glottis, larynx, and trachea,—and a sufficient number of cases have been examined,—the presence of false membrane in the named parts, all these seem to point to the conclusion that this disease is allied to the epidemics of diphtheria of the human family. The acute anæmia so generally observed is another proof of the diphtheroid character of this epidemic. The disease broke out in the far East during the autumn, when the cold, damp atmosphere and the prevalence of catarrhs at this season of the year furnished sufficient material for the development of diphtheritis.

This horse epidemic of October and November, 1872, by the rapidity of its spread, the universality of its attack,—few horses escaping,—and by its great fatality,—out of thirty thousand horses owned in Philadelphia, according to the official reports over twenty-two hundred and fifty died in less than three weeks,—marks an epoch in the history of epidemics.

A BRIEF REVIEW OF THE REPORTS ON SCARLET FEVER AND DIPHTHERIA PUBLISHED IN THE "TRANSACTIONS" OF THE MEDICAL SOCIETY OF THE STATE OF PENNSYLVANIA FOR 1871.

BY HIRAM CORSON, M.D.,
Maple Hill, Montgomery Co., Pa.

FOR more than twenty years I have in numerous essays pressed upon the profession the importance of the use of ice, internally and externally, in the treatment of scarlet fever and diphtheria; the value of pouring cold water on the head when in grave cases the brain is affected, and of sponging the surface of the body with cool or cold water to allay excessive heat of the system. My experience teaches me that the gravest cases can be thus controlled. From various parts of the country comes the most cheering testimony in favor of the practice from physicians who have tried this cooling treatment, but yet the great majority of practitioners adhere to the old, empirical, and fatal routine practice. In order to present the subject to your readers in its proper light, I will give a brief review of the modes of treatment made use of in the various counties of our State, that they may see what claims they have for our confidence: nor need I render any apology for so doing, in view of the great prevalence and fatality of those diseases, as set forth in those very reports.

In the Mortuary Report of the City of Pittsburg, the Health Physician, J. Guy McCandless, in Class 1, Zymotic Diseases, gives the number of deaths from each disease; from which it appears that the deaths from scarlet fever and diphtheria were 225, only 45 less than from all other zymotic diseases together, excepting only cholera infantum, namely: smallpox, measles, croup, erysipelas, pyæmia, uræmia, typhoid dysentery, congestive fever, diarrhœa, hooping-cough, typhoid fever, cholera morbus, cholera sporadica, cholerine, gangrene, syphilis, inanition, and intemperance. Nor does this report stand alone. Philadelphia in her Mortuary Table sums up the deaths from zymotic diseases to a total of 2480, of which 956 were from scarlet fever, 172 from diphtheria, and 316 from croup (a kindred disease),—1444 deaths from those three diseases alone,—being 408 more deaths than from all other zymotic diseases together, namely: smallpox, measles, hooping-cough, cholera, syphilis, hydrophobia, typhoid fever, typhus fever, spotted fever, relapsing fever, puerperal fever, malarial fever, and erysipelas. Although the mortality of scarlet fever has been a

subject of deep and painful thought to me for many years, I had not regarded it in the light in which those reports present it. As a slayer of the human family in our State, it yields the championship only to consumption, a disease confined to no locality, which has for its field of operations every foot of our Commonwealth, and "has all seasons for its own." Let us look for a moment at those two diseases which, under the name of blood diseases, have caused physicians to seek after some remedy which, by a chemical or by an antiseptic influence, could neutralize the morbid matter which they believed was acting deleteriously on the blood, and through it poisoning the whole system,—a belief which blinded them to the fact that a fearful local inflammation was rapidly obstructing the principal avenue to life. In both of those affections Death comes to the patient with his grip upon the windpipe,—though he may sometimes, at the onset, stun him for a brief period by a blow on the brain.

And now let us see how the treatment in common use is adapted to ward off the King of Terrors. He uses no strategy, but comes boldly to the work. And what do we? While he is stunning the brain, we are giving chlorate of potash and brandy to produce some effect on the blood; while he clutches the throat, we apply fat meat to the neck and grease the body with lard, but raise not a finger to loosen his grasp. But I must not anticipate; let every county speak for itself. Dr. Asdale, of Allegheny county, had "twenty-two mild cases, requiring but little medication, and nine malignant ones, of whom five died." Omitting what he says of the mild cases, we will consider the grave ones:

"They are characterized by a sudden and violent accession of fever, generally preceded by vomiting; all marked by convulsions, and it was invariable in the fatal ones. In one case convulsions ushered in the disease, abating on the second day, death occurring on the fourteenth. In another, convulsions and death on the first. In the third, death in convulsions on the second. In the fourth, death in convulsions on the third day. In the fifth case, convulsions occurred on the fourth day, and the patient died on the seventh. In all, the eruption was well marked, being florid on all parts of the body, except in one, distinct only upon the face, and in that death occurred on the first day. In all, the pulse was from 120 to 160; temperature very exalted, one case on the second day being from 104° to 105°; in another from 105° to 106°. The former recovered after a protracted convalescence, the latter died. In numerous cases *the throat was at an early period most seriously involved;* in several, *pain in the throat was the first symptom* of the approach of the disease. In such cases the tonsils would become much enlarged, followed by extensive sloughing, extending low in the pharynx, in one case involving the larynx also, the patient having a rasping croupy cough, and difficulty of respiration. In one case, sloughing of the cervical glands was so great as to lay bare the muscles of the side of the neck."

While I have not quoted every word of Dr. Asdale's description of his nine malignant cases, I have omitted nothing of importance. Five of them defied his treatment, and some of the other four recovered only after a "protracted convalescence." My only object in this essay is to turn the attention of the profession to the utter inefficiency of the treatment almost universally resorted to in severe cases of scarlet fever. The above cases so well described by Dr. Asdale are very strong specimens of what are called grave cases; and now let us see what the treatment was:

"In all the severe cases in the acute stage, frequent anointing the body with lard was practised, to the great relief and often decided benefit of the patient. In several cases sponging with spirits diluted with warm water was used with marked reduction of temperature, and, as in the former case, with a soothing and agreeable influence. Cold affusion not practised. Cold drinks *allowed if desired*,—generous diet. Of therapeutic agents the bromide of potassium will claim the first place, very marked benefit being apparent from its use in five to seven or ten grain doses; in all those cases in which nervous phenomena were predominant, combined with tincture of aconite in *tolerably large doses*, and occasionally the addition of carbonate of ammonia, seemed favorably to combat the ataxic symptoms. Further in the cases, carbolic acid, quinine, and stimulants gave results highly gratifying."

Such was the treatment of nine grave cases, five of which died; and yet the means used are spoken of as producing "great relief and decided benefit to the patient," "combating favorably the ataxic symptoms," and producing "results highly gratifying."

As I read Dr. Asdale's treatment, I seem to be with him in the sick-room. It is his first visit, and the patient, a little girl of five years, is in the condition of which he speaks. Yesterday she was attacked by pain in the throat; to-day the throat is seriously involved. Pulse 120 to 160; heat of body 104° to 105°; skin florid; convulsions threatened.

There is no mistaking the disease. We have before us a grave case of scarlet fever. The family are affrighted; and as Dr. Asdale looks at the swelled tonsils, feels the rapid pulse, the burning skin and twitching muscles, and hears the mutterings of delirium, I see in his face despair take the place of hope. He remembers how often in times past, *in grave cases*, he has seen the utter worthlessness of the remedies recommended by authors and teachers. It is not a week since some of his patients in another street were carried off. With me, too, memory is busy. Scenes and incidents of forty years ago are before me; loved ones confided to my care are dying from scarlet fever; mothers are mourning for their children, and will not be comforted; while I, agonized and bewildered by my want of success, though using the means recommended by high authority, try to comfort myself by the assurance of teachers and authors that there "are cases in which no treatment will avail,"—a doctrine as erroneous as their treatment. But Dr. Asdale will do what he can for the case before him, and once more (despite all his former experience) he directs the mother to grease the body with lard (and speaks approvingly of the fat bacon which is already around the throat), and leaves some bromide of potassium, seven grains to be given at a dose, with "tolerably large doses of aconite."

And now we are about to leave, to visit other patients, and will call here again to-morrow to see

the effect of our remedies. Dear child of a loving mother, are you to be left now for twenty-four hours with no defence against the terrible disease which is swelling your tonsils, bloating up your throat, inflaming your nose and sending a burning flame into your windpipe; which is making your heart drive the blood through the arteries like a steam-engine; which is burning your skin and setting your brain on fire, and is just ready to throw every muscle into spasms,—with no defence, I say, against all this but a little lard, a few grains of bromide of potassium, and a few drops of tincture of aconite?

In behalf of the poor child, I ask, cannot we do something to relieve the swelled and burning throat and arrest the swelling of the glands which in your former case sloughed and laid bare the muscles of the neck, and involved both pharynx and larynx? Can we do nothing to allay the terrible heat of the skin,—ay, of the whole body? Nothing to avert the convulsions which are even now beginning to show themselves? He answers, "We are already using the regular treatment of the books for scarlet fever." I reply, Oh, doctor, if we could only forget the *name* of the disease, and prescribe for the suffering body; relieve the brain by *pouring* water on the head; cool the burning skin by sponging it all over rapidly with cold water, until the temperature should be reduced to 100°; give it ice, or iced-water or iced-cream, in its mouth, to cool its burning and suffering throat; apply ice in bladders to the glands of the neck, to avert the inflammation from them, we might then go away and return to-morrow to see our patient comfortable, and her mother's face radiant with joy. But we went away without doing those things. The lard was rubbed on the body, the bromide and aconite were given "to combat ataxic symptoms," the throat and brain were left to suffer, the temperature of the skin, 105° to 106°, was not attempted to be allayed; Death had it all his own way, laughing, as well he might, to see the bromide hunting him through the blood, while he sat enthroned and in full view on the brain, with his hands clenched around the throat, strangling his victim.

In Beaver county, Dr. Jackson reports eight mild cases and one severe one. "Treatment consisted mainly in the use of diffusible stimulants and tonics and externally stimulating and disinfecting lotions. The case ultimately recovered." The last sentence indicates that even that one severe case barely recovered. Look at the treatment. A child in full health taken sick with a febrile disease and an inflammation of the glands of the throat and neck, and the doctor pounces on it with stimulants outside and stimulants inside!

Let us go on to Bradford county, and see what our excellent friend Dr. Horton has done. He says,—

"In November and December scarlet fever appeared in a *grave* form. Depletion and evacuants were badly borne; tonics and stimulants frequently failed. The use of cold, though perhaps more successful than hot applications, has not always been satisfactory."

Well, there is a grain of comfort in the fact that some departure from the old kind of treatment was tried; though, as we know not how any of the means were used, we can profit but little from the report.

Columbia and Montour,—Dr. Suisher reports,—

"In the early part of last December scarlet fever attacked only a few families. It was of the most malignant type I ever witnessed. Of thirteen cases, six died, one a young man twenty years of age. In all the cases except one, death took place in less than forty-eight hours from the invasion of the disease. *The vital forces were so prostrated by the poison of the disease that reaction could not be established.* In no case were the throat-symptoms severe. Treatment appeared to be of little if any avail."

But, mark, we are not told how they were treated: had we been, we would query whether some other mode might not have done better. Indeed, from what Dr. S. says of a subsequent visitation of the disease, and of another mode of treatment, we believe he will soon be able to master cases like the above.

Now here let us pause a moment and look at the disease as it confronted the doctor. There lay the patient, with his vital forces so "prostrated by the poison of the disease that reaction could not be established, and treatment appeared to be of little avail." (What a boon it would be to know the treatment, so that we might avoid it!) But what are the vital forces of which he speaks? It is important to know what is meant by the phrase, for it is in the mouth of every man who meets with a case which proves fatal. The vital forces are prostrated. Do we mean by this that the blood is filled by a peculiar poison, which has changed it from a healthy to a morbid state, and that in this diseased condition it fails to nourish the body and thus death ensues? The early and persistent use of stimulants so early resorted to in such cases, to sustain the sinking or prostrate vital forces, while at the same time antiseptic remedies and chemical antidotes are given, indicates such a belief. And yet it is an erroneous belief, or else the treatment founded on it is not appropriate, for it does not succeed, and in nearly all such cases the physician writes, "treatment was of no avail." Or do we believe that this prostration of the vital forces, manifested by great muscular debility accompanied by increasing dulness of intellect or deep coma, is due to a *weakened* nerve-force caused by some noxious agent acting primarily on the nervous system, and thus prostrating the vital forces (for what is the vital force but the nerve-force?), as occurs in instantaneous death produced when prussic acid is applied to the nose or tongue of a dog, or in death which ensues in a few minutes after strychnia is inserted into his thigh, as occurred in Pennock's experiments?

(To be continued.)

Extraordinary Fecundity (*British Medical Journal*, Nov. 30).—The following is a copy of a newspaper paragraph, cut out some time ago. "The *Northern Ensign* states that a shepherd in the parish of Latheron, named Cameron, who has reached the patriarchal age of seventy-six, has just become the happy father of his fourth child since he passed his seventieth year. When seventy years old, he was married for the second time; and the produce of the second marriage has been four thriving 'coasters.'"—S. H.

CASES OF CEREBRAL MENINGITIS.

BY JAMES D. McGAUGHEY, M.D.,

Wallingford, Conn.

(Concluded from page 197.)

CASE III.—James K., aged 24. Has been tuberculous for several years; cough, expectoration, and hemorrhage. I had been attending him on account of a fresh tuberculous deposit at base of left lung, which ripened and discharged itself through the bronchial tubes. Expectoration and cough grew better, also the pleuritic and neuralgic pains that had troubled the left side and intercostal spaces,—these had previously been sources of great distress. The patient, feeling much better, and his condition greatly improved, though suffering from weakness, concluded to visit a relative, living at some distance, on horseback. He had complained of headache before starting, which in a day or two increased to such severity as to compel him to return home and go to bed. When I saw him again, cough had increased a little, also expectoration and the pains throughout the chest. The pain in the head now was intense, and was greatly aggravated on moving or from any jarring noise. Pain radiated over the whole head, extending into the eyes, sides of the nose, and down into the jaws, back part of the head, and down the spinal column. No delirium. Pain steady, with the exception of occasional paroxysms that produced the keenest suffering. Lies with eyes half closed; they were intolerant of light, though hearing was morbidly dull. Face flushes occasionally, but generally of pale or natural color. Heat of head not abnormal to the hand. Pupils do not respond well to light. Tongue moderately furred. Respiration not greatly hurried. Pulse 60, of a slow, reluctant beat, irregular. Bowels constipated. This is a general history of the case. It progressed with but little variation in the symptoms for three or four days. Some time during the fourth day delirium came on, and the general quiet which the patient had maintained was broken up, and he became very restless; pupils contracted; complete anorexia; feet cool pretty much all the time. Up to this period the treatment consisted principally in moderating the vomiting; overcoming constipation; quieting pain; perfect and absolute stillness in the room; *large doses of iodide of potassium;* blistering over nucha. On the eighth day no change, but a gradual aggravation of all the symptoms; debility becoming more evident, with increase of delirium. Quinine and nux vomica, combined with the cautious use of brandy, were given to sustain life. On the ninth day the delirium assumed a more violent type; patient would forcibly get out of bed and attempt to go out-doors; wild staring look; spastic contractions of the muscles of the neck, and general tonic spasms. Tenth day, lies with eyes half closed; squinting superadded; eyes infected. From this time forward, symptoms grew worse rapidly; countenance of a dark bronzed hue. After a partial convulsion, lost the use of the tongue. Pulse 99 and irregular; surface rather cool, with a slight clammy moisture; bowels not moved for four or five days. Twelfth day, talks incoherently, or rather mumbles, as the tongue is still entirely paralyzed; utter delirium,—entirely unconscious of any one around; pulse weak; will take no medicine; urine dribbles away involuntarily; comatose condition prevailing; respirations irregular; carphologia; paralysis on left side, and, twenty-four hours thereafter, death.

Remarks.—That a considerable number of cases of pulmonary tuberculosis die with tubercular meningitis, there is no doubt; and that that mystical entity, scrofula, is either identical with or closely allied to tuberculosis of the lungs, and renders the nervous system of those suffering under its affixation to the economy more liable to disease, especially of the brain, is becoming more widely recognized every day, and such diathesis of the system taken more into consideration in the treatment of disease. Though tubercular meningitis is much more common in children than in adults, it is by no means a rare disease in the latter; for I know of at least three cases that died not very far distant from each other. It appears to me of some moment to discriminate between those cases of true pulmonary tuberculosis *dying with meningitis*, and those dying in far-advanced consumption,—the system debilitated, worn down,—anæmic, cachectic, with strong cerebral symptoms. In the former the secondary inflammation is set up by actual deposit in the brain (I am not aware of any existing facts going to show that inflammation of any of the cerebral organs precedes the deposition of tubercle), causing meningitis; in the latter the phenomena pertaining to the brain are produced by *cerebral exhaustion* from *inanition* of the nervous system. Thus, the vice being in the lungs, they are slowly consumed, and commensurately with the ravages of the disease in the lungs the entire system sympathizes, and the functions of all the organs are impaired; digestive powers are perverted, assimilation of food imperfect, and the nervous system, failing to receive its wonted healthful stimulus, starved as it were by the unwholesome ingestion of devitalized blood, sets up those cerebral symptoms which are observed in the winding-up of many long, exhausting, and debilitating diseases, as, for instance, the cerebral and spinal symptoms of typhoid fever, called by some *subacute* meningitis, but really a *subacute* exhaustion if anything. We see coma in exhaustion, as well as in acute inflammatory conditions of the brain. I saw a patient die from secondary meningitis produced by concussion of the brain, some years ago; and as he lay in partial coma, with muttering delirium, face deadly pale, cold extremities, and involuntary discharges from the bowels, his attendants, two physicians of twenty years' practice each, strictly prohibited the use of brandy or quinine, fearing it would increase the inflammation or *reproduce* it, when the ebb of life was so low and feeble in the system that the pulse at the wrist was *imperceptible* for three or four days before death. Here then was a patient with complete cerebral and nervous exhaustion, dying for want of proper stimulus, because his case was looked upon as still acute,—simply as it was the brain suffering; forgetting the point where the acute left off and cerebral and general nervous exhaustion came in; forgetting that cerebral exhaustion is the *same in all cases*, whether coming from extraneous organs or the *brain itself*. Then of how great importance it is, not to confound *acute* cerebral symptoms with the same symptoms produced by *exhaustion!* The epiphenomena of the nervous system are so puzzling and peculiar that often cause is confounded for effect, and *vice versâ*. The case now under consideration did not present long-continued or far-advanced phthisis; there was physical evidence of a deposit, softening

and discharge of a tuberculous mass, with subsequent cicatrization, or at least cessation of discharge from the vomica; cessation of cough and pain, the pleuritic pain, and intercostal neuralgia; return of appetite, so that the patient was able to ride on horseback two or three miles. Then meningitis commenced; shortly thereafter, lung-trouble increased, pain in left side became troublesome, expectoration more abundant, return of cough, showing the tendency of tuberculosis, manifested a more general determination of visiting the brain as well as lungs, and perhaps other organs of the system. After the hopeful lull came the fatal reproduction of tuberculosis.

Williams gives in Case 77 of his work on Consumption a history of a case of acute tuberculosis dying with tubercular arachnitis, and says, "Four days ago came on pain in the head and intolerance of light, with fetid discharge from left ear; *increase of cough, feverish heat*, etc." Tubercles were found scattered through the lungs and spleen; granulations in the peritoneum and on covering of the liver; and in the *arachnoid* and *choroid* plexus of the brain. I am sorry I was not allowed to verify my own diagnosis by a post-mortem.

Case IV.—Was called to see a young lady 24 years of age, unmarried, who had been indisposed a day or two; she complained of nothing particularly, excepting a general inexplicable bad feeling, amounting to malaise, anorexia, slight, dull pain in the head; but little fever, pulse quiet. A close examination elicited nothing as to the cause, and I concluded the symptoms were from cold, etc.; gave a mercurial cathartic, to be followed by salts. I found the patient in a day or two a great deal worse; pain in the head greatly increased, extending from the occiput to the forehead. Pulse 80, with a peculiar, contracted, reluctant beat; eyes dull-looking, countenance of a bronzed hue; somewhat intolerant of light and sound; gastric disturbance, also constipation. Pain in the head increased, with delirium; shouts, sings, and whistles; dark suffused look of eyes and face; eyes seem to hang or project out on to the cheeks, bringing into view almost two-thirds of the globe, a phenomenon I never saw before or since in meningitis. Very drowsy, stupid, and dull. After severe, hard, and persistent purging, pulse ran up to 120, and after three days commenced gradually declining, and patient recovered in about three weeks.

The only way I could satisfactorily account for the attack was this: the young lady had a very fine head of hair, and of course was very proud of it, and, to stimulate its growth and keep the scalp free from dandruff, would saturate the scalp thoroughly with Ayer's "Hair Vigor" very often, and then sit before the fire until the hair became dry enough to put up. I supposed the sugar of lead contained in the above preparation to be the prime cause; either in producing a retrocession of some scalp-eruption, or by being put in such close contact with the brain, through absorption, setting up an inflammation by some way or manner inexplicable. If I remember rightly, the analysis of hair-preparations, made at the Bellevue College, gave that of Ayer as containing fifteen grains of acetate of lead to the ounce, a larger amount than in any of the other fourteen preparations examined.

TRANSLATIONS.

OUTLINES OF A SYSTEM OF PHYSICAL OTIATRICS.

Translated from the German of Dr. Erhard, Instructor in the University of Berlin,

BY C. H. BURNETT, M.D.

(Continued from p. 184.)

Class III.—Those hard of hearing who perceive ordinary noises normally, but musical tones abnormally, *per ossa*. These cases are generally rare. Speech is heard always with difficulty, *i.e.*, practically not understood at all. If, at the same time, the hearing for noises *per cavitatem* is diminished, we may assume that deposits in the cavum tympani impede the action of the conductor of sound and interfere with the proper isolation of the ossicles, without, however, exercising any pressure upon the labyrinth-water, but that, with these changes, the resonance of the labyrinth-water has been destroyed, either on account of obliteration of the fenestræ or through absolutely defective consonance of the air in the cavum tympani. If, on the other hand, the conductor in the cavum tympani is normal, *i.e.*, if noises are properly conducted by it, but not musical sounds, we have either a case of defective innervation of the ramus, cochleæ, or of morphological changes in the region of the zonula membranacea. The most interesting case of the kind was the following: A patient lost his hearing for the human voice suddenly, after a plunge-bath, but retained a relatively good hearing for noises. Patient heard the watch *per ossa*, the scratching of a pen in writing was heard *per aërem*, and also a light tap at the door or window, but he could not hear the loudest words. I asked him to describe to me the impression my loudest speaking made upon him.

A high "i," a deep "u," a loud "a," he heard simply as unmeaning noises, or impulses in the air; as, for instance, "hst," "pst," etc.

Class IV.—Those hard of hearing who perceive, *per ossa*, both noises and musical sounds less than normally. The degree of the loss of hearing varies, amounting in some instances to *total* deafness for ordinary sounds, and in others for musical tones. Under this head we have several subdivisions.

1. In some cases of weakened hearing *per ossa*, we find the ability to hear relatively well both noises and musical tones *per cavitatem; i.e.*, they hear speech relatively very well. In such cases, if the entire conducting apparatus as well as the pressure and resonance are normal, and the Eustachian tubes are in a state of integrity, the cause of the existing alterations in function must be sought for in defective innervation of both branches of the acoustic nerve, caused by morphological changes in its terminal apparatus.

2. More frequently we meet at the same time with a diminished conduction and resonance in the cavity of the tympanum. In such cases, the altered function is due to deposits in the cavity of the tympanum, which interfere with its functions and at the same time press upon the water of the labyrinth, overcome the elasticity of the membranes of the foramina, and also bring about cellular irritation in the contents of the labyrinth. This is usually the termination of those cases of at first slight, yet constantly increasing, deafness, which are caused and kept up by insufficient ventilation in the cavity of the tympanum.

3. Absolute deafness *per ossa* is finally succeeded by deaf-dumbness. This loss of hearing is partly caused by central paralysis of both acoustic nerves, induced by extravasations and exudations at their origin, resulting from concussion, apoplexy, hydrocephalus, etc., or in some cases the cause may be hyperplastic processes in

the labyrinth, as in meningitis cerebro-spinalis. In these cases we see unsteadiness of gait, titubation, etc., as the result of the pressure of the hyperplastic process upon the membranous labyrinth.

Congenital absolute deafness is rare.

Temporary absolute deafness may arise from excessive pressure on the external meatus, in cases of furuncle, or it may arise from an instantaneous closure of the Eustachian tube. In this connection, the following case is instructive: I was informed that an apothecary's apprentice became deaf every day in the forenoon, when he was especially engaged among acrid and irritating drugs, and this deafness remained several hours when it had once set in. At the time of the first examination I discovered nothing but a catarrh of the pharynx, and I was forced to conclude that the extraordinary symptoms of deafness were produced solely by portions of mucus forced into the mouth of the Eustachian tube, and thereby cutting off the supply of air in the tympanum, which was brought about by the accelerated inspiration and expiration induced by the action of the irritating drugs upon the inflamed mucous membrane. I intimated to the patient that I would examine his hearing after the use of some smelling-salts and the introduction of air into the tympanum, *lege artis*. The robust, healthy, normally hearing patient applied a bottle of acetic ether to his nose, snuffed at it strongly, fell senseless to the floor, and became absolutely deaf to the loudest noises and notes, both *per ossa* and *per cavitatem*. It was necessary to shake him into consciousness; yet upon introducing air into the tympanum all these strange symptoms instantly disappeared. His ability "to hear" or "not to hear" was completely within my power, and I could show him to my pupils as I would an apparatus illustrative of physical experiments in acoustics. Recreation and cessation from his ordinary labors cured the catarrh, and with that the above-mentioned phenomenon disappeared, which, while it was present, demonstrated so forcibly the intimate connection of the single part of the organs of hearing with the whole.

In conclusion, I would mention a few observations which seem to indicate an altered reaction of the zonula membranacea. Just as we, by pressure upon the pedal of a piano, are able to alter the "clang-tint" of the instrument, so may a specific pressure upon the labyrinth-water, or directly upon Corti's organ, alter—*i.e.* heighten—the fundamental note of the fibres of the organ of Corti.

In inflammations of the external meatus, which alter, as has already been shown, the pressure in the organ of hearing, temporary double hearing may occur, so that an instrument is heard as though it possessed two clang-tints, the healthy ear perceiving the normal clang-tint and the diseased ear the abnormal clang-tint. This phenomenon disappears with the cessation of the inflammation. As in a piano, if certain strings are broken, they only cease to sound, so in the zonula membranacea, which has different fundamental notes at different localities, certain portions may suddenly lose their resonating power (usually produced by concussion at these points), and although the general hearing-power may remain unaltered, the power to perceive the notes corresponding to the defective spots in the zonula membranacea will be destroyed.

Thus we may account for the inability on the part of some individuals to hear canary-birds, although they are able to hear a thrush; neither can they hear an ordinary post-horn, but they perceive perfectly the tones of a piano or violin.

Thus we are enabled, by the pathological physics of the organ of hearing, to establish Helmholtz's theory of vibration.

Without definite acoustics, there can be no advance in Otiatrics.

Wound of Abdomen, with Injury of Intestine—Recovery (By Henry Horton, M.R.C.S., Eardisley: *Brit. Med. Journal*, Sept. 28, 1872).—On August 9, 1865, late at night, I was called to see F. M., a woodcutter, who, as the messenger most truly described the case, had walked into the town with his intestines in his hand. He had brought wood into the town, and was returning, as was his custom, with a bottle of rum inside his guernsey. When about a mile or so on the way home, the night being very dark, he drove his cart into a pit. He was thrown off, and the bottle was broken into several pieces. A portion, in shape like a huge lancet, penetrated the abdomen to the left, and about two inches below the umbilicus, making an irregular-shaped wound externally, cutting through the large omentum, and dividing the peritoneal coat of the jejunum. Protrusion occurred on his rising, and increased at every step until he reached the town; so that when I saw him there were from ten to twelve inches of intestine and a rather large piece of omentum to be dealt with. There had not been much bleeding, but the omentum was darker than natural, and, as also the protruded bowel, quite cold. As there was not much prostration, and the patient was otherwise in good health, we (another practitioner had been sent for and arrived about the same time) thought it the best course to return all *en masse*. This was done, and five silver wire sutures were applied. Full doses of opium with a little calomel were given every two hours. Next day, August 10, I saw him twice, as there was a good deal of tenderness and threatened peritonitis; but, on the whole, he had passed a tolerable night. He was ordered to continue the powders. On August 11, 12, and 13, he was seen once daily, and nothing special had then occurred. On the 14th, there was very great distention of the abdomen from fluid, so that I had to loosen the lowest suture; when, after turning the patient as much as possible into the prone position, a great quantity of bloody, grumous-looking contents escaped, to the great relief of my patient, and, I must say, to my own personal alarm. On the 15th, the condition was even more alarming; and, as he complained of very great thirst, I gave him an anodyne mixture with mineral acid. This state of things continued for the next three days, and each morning a further quantity of fluid was evacuated from the abdominal cavity. On the 19th, a gradual improvement set in, which continued without any drawback until August 30, on which date I took leave of my patient, who, in a few days afterwards, resumed his ordinary employment.

I saw him several times during the next three or four years, and the only complaint was that he sometimes felt a little "pinching" just at the part injured, and which, I suppose, was the result of the omentum becoming adherent to the abdominal wall at that spot. In every other respect he declared that he was as well as he ever had been.

Syphilitic Infection by a Lozenge (*British Medical Journal*, Nov. 30, 1872).—Dr. John Murray says, "When attending the clinique of M. Hardy at the Hôpital St. Louis, in Paris, I saw a case of syphilis of a similar character to that mentioned by Dr. Drysdale, of infection from smoking a cigar. The subject was a child of about five years of age, who was brought to the hospital with a cutaneous eruption of an unmistakably syphilitic character, combined with other constitutional and local signs, the exact nature of which I now forget. M. Hardy was at first unable to trace the infective cause. He at length discovered that the child's brother was the subject of constitutional syphilis, and that some time previously he had, before the young patient presented any symptoms, given his sister a lozenge to suck, which had been partially dissolved in his mouth, and had thus infected the child."

PHILADELPHIA
MEDICAL TIMES.
A WEEKLY JOURNAL OF
MEDICAL AND SURGICAL SCIENCE.

The Philadelphia Medical Times is an independent journal, devoted to no ends or interests whatever but those common to all who cultivate the science of medicine. Its columns are open to all those who wish to express their views on any subject coming within its legitimate sphere.

We invite contributions, reports of cases, notes and queries, medical news, and whatever may tend to increase the value of our pages.

All communications must bear the name of the sender (whether the name is to be published or not), and should be addressed to Editor Philadelphia Medical Times, care of the Publishers.

PUBLISHED EVERY SATURDAY BY
J. B. LIPPINCOTT & CO.,
715 and 717 Market St., Philadelphia, and 25 Bond St., New York.

SATURDAY, JANUARY 4, 1873.

EDITORIAL.

WONDERFUL VITALITY.

THROUGH the kindness of "a medical student," to whom we hereby return our thanks, we have received a copy of a most extraordinary publication. It is called "*The Journal of Progressive Medicine*," and purports to be the supplement of vol. x., No. 3, for May and June, 1872, issued by the American University of Philadelphia, 514 Pine Street. As the charter of this institution was revoked in April, there would seem to be here a sort of post-mortem parturition, unless a school can be carried on without such an instrument.

This school, however, ought to be not only in existence, but flourishing, since they make, after stating their thirty-five-dollar fees for the course, this truly generous offer: "Fifty young men, who believe in Eclecticism and the American system of practice, who are unable to pay the above fees, if recommended by a liberal physician, will be taken free of all expense." Assuredly the Professors must be men of private fortunes. For, supposing them to succeed in getting four hundred students at the above-mentioned rate, the income they would have to divide ($12,250 among eight) would give each one only a little over $1500. Since, however, they have not one hundred students (see the testimony before the Select Committee of the State Senate), the gross proceeds of each Professor's teaching cannot be much over $400; which would obviously be lessened by one-half if the number of beneficiaries on the free list were filled up. Hence we must either ascribe to this faculty a superhuman generosity in making such offers, or suppose them gentlemen of private fortune, who engage in teaching purely as a matter of taste, and not with the sordid view of making a living. No, one other theory suggests itself,—that they eke out the certainly scanty returns from their classes by selling diplomas to any and every one who will buy them.

As to the matter of the charter, we will let "Dr. Joseph Sites, Dean," speak for himself and colleagues; which he does in the following extraordinary specimen of bad grammar and mixed metaphor:

"In 1860 corrupt influences were at work, and a secession took place from our school; the seceders obtained a Charter from the Legislature, calling their school the Eclectic Medical College of Philadelphia, announcing themselves as true Eclectics—a name so near ours well calculated to deceive. Many times have they changed their name, and been guilty of various corrupt practices, which has brought our noble profession into disrepute. We have repeatedly, in the past, warned the profession through the journal and otherwise, against the machinations of the parasite. We have done our best to prevent such impositions on the public and profession, but in vain. Their acts have become so bold that the press took notice of them, and by this means their defects were brought to the notice of the Legislature, who repealed their charter with many names.

"Thus terminated the foul blot upon our profession. As their name was so near ours as to deceive many, we have concluded to accept of a University Charter which has been generously granted us by a liberal-minded Legislature; under this we propose to conduct our school—under this we propose to unite the profession of our city and State—every element of strength, viz., THE AMERICAN UNIVERSITY OF PHILADELPHIA.

"The University is to be intrinsically, essentially and eternally Eclectic; the principles of Beach are to be its guiding star—the true American system of practice.

"This course is deemed advisable for several important reasons:

"It obliterates all the old prejudices of the rival schools, and harmonizes the profession. Students prefer to graduate, in all cases, from a University to that of a College. It gives them a better standing in the profession and among the people. It opens a more diversified field, and will enable us to open up a Department of Arts and Theology as well as Medicine.

"The Addendum" (!) "Degree of the University will be conferred upon all the living graduates of the Eclectic Medical College of Pennsylvania, thus bringing every graduate under the folds of the University, the only Eclectic University in the world. A new era of progress is upon us, and we call upon Eclectic physicians throughout the State to unite to form county societies

at once; to pledge themselves, by all they hold dear, to arrest the intolerance of Allopathy, and shun the expectant treatment of the Homœopath. War has been declared; truth can never be obliterated. All we need is united effort and labor. Pledge your senators and representatives to our school in your different districts. Do it now—do not delay—let your manhood inspire you—bear in mind that you are an American, and that no money of the Allopath can enslave you—that freedom to you in medicine, as in religion and politics, is as essential to you as the air you breathe."

In plain language, this thing is a most infamous evasion of the law. The whole concern is a humbug, of which we shall warn the profession, and the public so far as we can, at every opportunity. Sites, Buchanan, and their less notorious colleagues are engaged in a scheme for swindling, or enabling others to swindle, every community among whom a medical degree can be used as a passport to practice. The honor of the profession, no less than the interest of humanity, calls for their effectual suppression at the earliest possible moment.

A RENEGADE.

IN the list of former Vice-Presidents of the American Medical Association may be found the name of Christopher C. Cox. We shall go no further into his history than to say that we can bear testimony to his having been on more than one occasion an irrepressible nuisance at the meetings of that body, over which, however, we believe he never presided.

We merely wish now to quote the following passages from *The Ohio Medical and Surgical Reporter*, a homœopathic journal, for September, 1872, and to express the hope that Dr. Cox's name will be ordered to be erased from the list of members of the American Medical Association at its next meeting.

The article is headed "'Medicine as a Liberal Science,' by Dr. C. C. Cox, Washington, D.C.," and begins, "At the reception given to the American Institute of Homœopathy by Governor Cook, of the District of Columbia, . . . Dr. Cox said, 'It is not necessary to assure you, gentlemen, how sensibly I feel all the kind expressions I have heard here to-night, and on prior occasions since your Institute has been in session. . . . I need not say to you that I do not feel myself degraded by the company in which I find myself, but, on the contrary, I will assert that I feel myself honored. . . . The time will never come when I, as a member of any body engaged in service for the public good, shall stop to inquire whether the man who sits next to me is a disciple of Galen or of Hahnemann. . . . It is presumption for one class of men—and in this connection I regret to allude to the American Medical Association—to say that because one is of a particular color, or believes in the doctrines of Hahnemann, or he or she entertains opinions of their own in regard to the practice of medicine,—it is the height of presumption, I say, for any class of men to say that against such applicants the doors of the temple of science are to be closed. . . . I wish to say here that it is alike the duty of Allopaths and Homœopaths, as a body of devotees to science, to join together in an effort to break down the barriers of bigotry and prejudice that exist to-day (cries of Good! Good! and applause). It is our duty to stand together in an effort to put down exclusiveness.'"

PROCEEDINGS OF SOCIETIES.

PATHOLOGICAL SOCIETY OF PHILADELPHIA.

THURSDAY, NOVEMBER 14, 1872.

THE PRESIDENT, DR. J. H. HUTCHINSON, in the chair.

DR. JOHN S. PARRY exhibited a specimen of *primary cancer of the vagina* which had been removed by *scraping*. (The case will be published in a later number of the *Medical Times*.)

Dr. J. EWING MEARS desired to know whether Dr. Parry limited this treatment to cancer of the vagina. He had frequently seen it used by Dr. Atlee in the treatment of cases where the seat of the affection was the os uteri.

Dr. PARRY replied that he did not say this treatment was very novel. Years ago Dr. Lunson, of Edinburgh, removed morbid growths by scraping, but used only the nails. Some French surgeons have also resorted to it, but it has never been systematically carried out. So far is it from being alluded to in the text-books that, on the other hand, we are urged to be careful lest we produce hemorrhage in the ordinary digital examination. Prof. Thomas, of New York, discourages the use of the speculum in such cases, lest hemorrhage ensue.

He did not think the danger from hemorrhage great, and scarcely considered it necessary to use the persulphate of iron to arrest it. Had he had proper instruments in his own case, he would not have used the subsulphate of iron to arrest the flow of blood with the removal of the diseased tissues. The hemorrhage grows less as we proceed. He would, however, use mild caustics, or Monsel's solution, to remove portions which cannot otherwise be destroyed.

Dr. H. LENOX HODGE said, in reference to the treatment of cancer of the vagina by scraping away the morbid mass, that although it may not be alluded to in the books, it has been at times resorted to. He referred to a case which occurred in one of our hospitals as long as twelve years ago, in which an eminent practitioner, while scraping away with his hand the cancerous mass on the posterior wall of the vagina, entered the peritoneal cavity, and fatal inflammation resulted.

Dr. JAMES TYSON exhibited a pair of *granular contracted kidneys* and a *congenitally deficient left lung*.

All were removed from a married woman, aged 38, who was admitted to the Philadelphia Hospital, October 18, 1872, and died on the 3d of November, in uræmic coma. The symptoms during her residence in the hospital were chiefly those of acute inflammation of the kidneys, deficient secretion of bloody urine, large quantities of albumen, blood-casts, hyaline and granular casts. Some of the latter were very long, and contained occasionally fragments of epithelial cells, but there were no epithelial casts. The quantity of urine ranged from a few drachms to six ounces in twenty-four hours, and the urea eliminated, as determined by volumetric analysis, was as low as twenty-five grains in the twenty-four hours. She was also the subject of general œdema, ascites, and hydrothorax. From the previous history, however, the diagnosis made was *granular degeneration of the kidneys*, on which an acute inflammation had supervened.

Post-mortem examination was made six hours after death. The *kidneys* were perfect examples of the chronically contracted organ, each weighing *three* ounces, but were also acutely congested.

The body was œdematous, as described before death. On section, hydrothorax of both sides, with some adhesion on the right by moderately recent lymph.

The *left lung* in its entirety was about one-third the normal size, composed of two lobes, an upper, larger, measuring four and a half inches by three and a half, with a teat-like projection, an inch long, of lung-substance projecting from its inferior anterior angle; and a smaller inferior lobe, measuring three and a quarter inches by two and a quarter. The first impression obtained on opening the thorax was that the lung had been compressed by the effused fluid; but further examination showed what seemed to be a congenital condition.

The *heart* was hypertrophied, weighing eighteen ounces. The mitral valves were slightly thickened, but otherwise normal.

The *left lung* was referred to the Committee on Morbid Growths, to be reported on.

Dr. TYSON also exhibited the *large intestine of a cat* which was the seat of obstruction about two inches below the ileo-cœcal valve. The animal had symptoms of obstruction for some time before death, chiefly constant vomiting of food, and almost total absence of discharges from the bowels. Extreme emaciation preceded death.

REVIEWS AND BOOK NOTICES.

ON SOME AFFECTIONS OF THE LIVER AND INTESTINAL CANAL, WITH REMARKS ON AGUE, ETC. By STEPHEN H. WARD, M.D. Lond., etc. 8vo, pp. 260. Philadelphia, Lindsay & Blakiston, 1872.

We have grouped together here a number of interesting articles, the introductory or didactic portion of each being illustrated by clinical cases, told in good, plain English, clearly and to the point,—possessing the advantages that history told with an object always has over even the most accurate reports of the best clinical clerk.

The diseases of the liver treated of are abscess, cirrhosis, hydatids, jaundice, and functional derangements. Then follow diseases of the intestinal canal, viz., obstructions, dysentery, peritonitis, perityphlitis; then malarial disorders, with scurvy, leuchæmia, and purpura. The book seems to contain few errors: however, on page 194, in regard to the return of arrested ague, the author says, "The period of relapse in the few cases in which I could determine it, having recurred on the day on which the fit would have taken place had the disease not been arrested." We should like to know how the author discovered this, his illustration of the above only serving to cast a denser gloom over the matter; as he says, "Thus I find in one case of tertian the fit occurring on the eighteenth day after the last, and in other cases on the twelfth."

The author recommends the giving of a full dose of quinia, ten grains or more, three hours before the expected return. He also brings forward additional testimony to its prophylactic power in small doses.

To the use of condensed water on shipboard he attributes many cases of scurvy. His reasons, insufficient indeed, are, however, strong enough to suggest further observation. The author is a believer in moderate medication. His treatment seems, throughout, sound and sensible, and the whole book well repays its readers; his cases being of that character best described by saying that one recognizes many of them at once as old familiar friends or enemies.

BOOKS AND PAMPHLETS RECEIVED.

Clinical Lectures on Diseases Peculiar to Women. By Lombe Atthill, M.D. Univ. Dubl., etc. etc. Second Edition, Revised and Enlarged. Crown 8vo, pp. 241. Philadelphia, Lindsay & Blakiston, 1873.

Surgical Diseases of Infants and Children. By M. P. Guersant, Honorary Surgeon of the Hôpital des Enfants Malades, Paris, etc. Translated from the French by Richard J. Dunglison, M.D. 8vo, pp. 354. Philadelphia, Henry C. Lea, 1873.

Aids to the Diagnosis of Diseases of the Kidneys. By W. R. Basham, M.D., etc. 8vo, pp. 48. Philadelphia, Lindsay & Blakiston, 1872.

An Examination of Professor Reese's "Review of the Trial of Mrs. Wharton for the Murder of General Ketchum." By Philip C. Williams, M.D. 8vo, pp. 31. Baltimore, Turnbull Brothers, 1872.

On the Use of the Seton in the Treatment of some Chronic Affections of the Womb. By Ely Van de Warker, M.D., etc. Reprinted from the *Journal of Obstetrics*. 8vo, pp. 16. New York, 1872.

Fœticide and Criminal Abortion: an Introductory Lecture. By Hugh L. Hodge, M.D. Fourth Edition. 18mo, pp. 55. Philadelphia, Lindsay & Blakiston, 1872.

GLEANINGS FROM OUR EXCHANGES.

ON PUNCTURE OF THE BLADDER PERFORMED IN THE HYPOGASTRIC REGION BY MEANS OF THE CAPILLARY TROCAR AND PNEUMATIC ASPIRATION.—M. Léon Labbé, in *The Practitioner* for October, 1872, says: There occur in practice a certain number of cases in which the natural passages do not permit us to penetrate into the bladder and to remove retention of urine.

Hypertrophy of the prostate, some very narrow strictures of the urethra, laceration of the canal caused by external traumatisms or by forcible catheterism, are the principal causes which bring on complete retention of urine, and give rise to indications for active surgical intervention bearing upon other situations than the normal passages.

Perineal puncture has been abandoned by surgeons as being a most detestable operation.

Recto-vesical puncture, more or less advocated at

various times by some surgeons, still enjoys a certain degree of favor; and quite recently, at the meeting of the British Medical Association, at Birmingham, Professor Pemberton related the results of his practice on this point.

In France M. Voillemier has employed, once only, *sub-pubic puncture*. The attempt was a successful one. But this is a procedure of somewhat difficult execution, and does not seem to exclude the possibility of wounding some important organ, or the liability to urinary infiltration.

Lastly, *hypogastric puncture*, effected by means of large curved trocars, has been generally accepted by French surgeons. A great many of them, however, think the procedure must be practised only as an extreme resource; and therein lies perhaps the cause of a great number of failures. Now, an attentive investigation of all the facts has shown, as is well brought out by M. Pouliot in his inaugural thesis (Ponction Vésicale Hypogastrique, Thesis No. 110, Paris, 1868), that—

1. In healthy men, almost all young, puncture necessitated by traumatic causes is almost without danger.

2. Chances of success diminish in cases of stricture, because in these instances we find among those operated on individuals who are exhausted by suffering, and reduced, as it were, to the condition of the aged.

3. Lastly, in senile affections, failure is about as frequent as success.

Under all circumstances, hypogastric puncture practised by the old rules, even in an individual placed in the best conditions, is an operation of some gravity, involving for the patient and the surgeon the necessity of minute precautions, with the object of maintaining the canula exactly *in situ*, for a time which varies according as the flow of urine through the natural passages is more or less rapidly re-established. This canula, or the permanent sound which was substituted for it in a certain number of cases, might irritate or ulcerate the walls of the bladder as the organ returned to its normal size. Urinary infiltration, resulting from the passage of the urine between the canula or sound when the bladder contracted, has been observed in some cases. Lastly, persistent hypogastric fistulæ, though they are rare, must be taken into account in appreciating the value of the proceeding.

It is a thing of habitual notice with surgeons who have had occasion to perform puncture of the bladder by whatever proceeding, that when once the bladder is emptied, and consequently the normal relations of this organ re-established, and when the tenesmus of the whole region is overcome, it becomes *generally* possible in a short time (a few hours, a day, two or three days) to re-establish the course of urine through the normal passages, whether the cause of the retention be due to traumatisms of the urethra, hypertrophy of the prostate, false passages produced by the hand of the surgeon, or very narrow strictures of the canal.

The knowledge of these facts naturally encouraged surgeons to seek for an operative procedure by means of which they might carry out the leading indication, namely, *to empty the abnormally distended bladder, and to gain time, so as to re-establish the natural passages without, if this be possible, causing the patient to run the risks of a serious operation.*

When M. Dieulafoy availed himself more completely than his predecessors of the notions which existed of the utility of capillary puncture on the one hand, and of previous vacuum applied to the aspiration of fluids on the other hand, and ingeniously combined these two means of action, he put surgeons in possession of a precious means of evacuating collections of liquids more or less deeply seated.

Dr. Labbé next details three cases, one attended with complete success, the other two with temporary relief only. He then gives three other cases, occurring under his own care during the present year, in two of which the benefit was complete and permanent, while in the other the patient sank from old lesions; and closes his paper as follows:—

"From all the foregoing facts the following conclusions may be drawn:—

"1. That capillary hypogastric puncture is a perfectly harmless operation.

"2. That in all cases it must be substituted for ordinary hypogastric puncture.

"3. That in a great number of cases it may, when only once practised, allow the surgeon to penetrate afterwards into the bladder through the natural passages.

"4. That in certain cases where catheterism is impossible, it may be performed three or four times a day without any injurious effect, and thus permit the surgeon to gain time and restore the natural passages; and at the very least it constitutes a palliative means of the highest importance."

Amputations at the Hip-Joint.—Three successful operations of this kind have been reported within the last year.

Dr. T. A. McGraw, Professor of Surgery in Detroit Medical College, reports one in the Transactions of the Michigan State Medical Society. The case was that of a man 54 years of age, who, when 16 years old, sustained a fracture of both thigh-bones at their necks, by the caving in of a bank of earth. Ten years ago, a small tumor appeared on the outer side of the lower third of the right thigh. This existed seven years, and was then removed by operation. Four times it recurred and was removed. He finally entered the Harper Hospital in Detroit, and on the 4th of March Dr. McGraw amputated the limb by large lateral flaps. There was no cachexia, and no involvement of lymphatic glands. A marked feature of the after-treatment was the use of oxygen gas by inhalation, as a stimulant. The only drawback to his recovery was an attack of erysipelas; but eight weeks after the operation he was about on crutches, and one month later he was driven two miles and assisted up two flights of stairs to get his photograph taken.

Mr. Morrant Baker (*Lancet*, Sept. 21), on the 15th of August, amputated the left thigh at the hip-joint, for necrosis, in a young man aged 22, a patient at St. Bartholomew's Hospital, London. Chloroform was given, and an abdominal tourniquet used. Antero-posterior flaps were made, and on Sept. 5 the wound is reported as rapidly healing, the last ligature having come away.

The third case is mentioned in the *British Medical Journal* of Nov. 23, as occurring in the Manchester Royal Infirmary. The report says, "The patient, a lad of seventeen, was admitted into the hospital, under the care of Mr. Lund, for spina ventosa of the lower end of the femur. On November 1, Mr. Lund amputated at the hip-joint; and at the present date (November 18) the wound and the lad are both nearly well. The operation, which was most skilfully performed, occupied thirty-five seconds, and was treated, both at the time of operation and since, on the strictest antiseptic principles, as, indeed, Mr. Lund treats all his cases. From first to last the boy has never had a bad symptom."

Phlegmon of the Scrotum with Issue of Lumbrici.—This case is quoted in the *Lancet* of Nov. 9, as recorded in the *Imparziale* of Florence by Dr. Termini. The patient was a child aged 10 years, who suddenly experienced severe pain in the scrotum. This was followed by the discovery of a phlegmon of the spermatic cord. Poultices were applied, and after seven days an abscess had formed. The gathering

was opened by means of a lancet, and poultices again applied. Two days after, a large worm was found on the poultice. Santonine was then administered, and was followed by the expulsion of eleven lumbrici through the scrotum, and of several others by the bowels. The child got better, but three months later Dr. Termini was again called in, and ascertained the existence of inguinal hernia on the right side, which was easily reduced. It is obvious that the hernia existed at the very beginning of the case, that inflammation supervened in the sac, and was followed by an abscess which broke of itself or was opened, and that the lumbrici which came out by the scrotum proceeded from the bowel. It is strange, however, that nothing is recorded as to the escape of fæcal matter with the worms, or the existence of any symptoms attending such an extensive laceration of the intestine.—(See *Phil. Med. Times* for Dec. 21, p. 178, for an analogous case.)

MISCELLANY.

The Key to the Chamber of Science.—*The Clinic* (Cincinnati) of December 7 contains the following:

"A physician in the vicinity of Lyons, Dr. X——, was called a short time ago to treat an accident as curious as rare in the annals of medical science.

"Startled in the night by a tumult at his gate, as uproarious as frequently repeated, the good doctor rushed to his window and demanded the cause of an alarm of this kind at so late an hour. It would be useless for us to attempt to report the conversation which occurred between our worthy confrère and the luckless messenger at his gate, so we will let the facts speak for themselves.

"An unfortunate female, living a short distance from Lyons, had suffered for several days with a violent pain in the side, radiating over the belly. Having exhausted, in vain, all the therapeutic skill of the good mothers of the village, she determined to resort at last, on the evening of the message to the doctor, to a method of treatment recommended by one of these dames, viz., the application of what is called in that section of the country an *aventure* (a cupping-glass). But as the pain was no longer confined simply to the side, but extended over the whole abdomen, the matron suggested the substitution of a common tea-cup or tumbler by a larger vessel, viz., an ordinary chamber. The patient caught at the suggestion, and the application was as successfully effected as the advice had been charitably imparted. The poor woman submitted to this strange procedure for a short time with a patience and good will entirely equal to the novelty of her situation. But after a short time, to her intense amazement and profound horror, her whole belly began to pass into the pot. She now commenced vigorous efforts to disembarrass herself from this engulfing apparatus. To her indescribable dismay, she found herself unequal to the task. Terrified now beyond measure, she began to cry out for assistance, and friendly neighbors rushed in from all sides to the rescue. They seized the vessel by the handle and rim and exerted combined efforts. All in vain. The pot stuck, and the poor patient, exhausted by anxiety and pain, surrendered in despair.

"It was at this juncture that Dr. X—— was called. The doctor took in the situation at a glance. Turning quickly to the door, he seized the key. One blow fractured the vase, and, to the unspeakable joy of the patient and the perfect stupefaction of the attendants, the poor woman was delivered back to life.

"There was homage then to the skill of the physician, and joy over the progress of science in our day."

Microscopic Eyes.—The following paragraph appeared in a recent issue of the *New York Tribune*:—"A boy with microscopic eyes is the latest scientific wonder in England. He possesses the faculty of seeing minute objects magnified to a marvellous degree. His eyes were diseased when he was young, and he came near losing his sight, which, however, he gradually recovered. It was found, however, that the internal structure of the eye had been changed, the cornea being greatly enlarged, the crystalline lens being divided into three different parts, each part surrounded with a light-blue circle; and in the centre of each appears the iris, diminished to the size of a pin's head. The patient cannot distinguish objects at a distance, they appearing blurred and misshapen. The magnifying power of his vision is stated at 5000 diameters. A curious fact is that he will never examine water, having once discovered the vast number of infusoria contained in some which he was drinking, and the sight of which thoroughly frightened him. The lad, it should be mentioned, has a wonderful talent for drawing and coloring with great accuracy the objects which come beneath his inspection. The case is under the particular attention of Sir Charles Madden, F.R.S., and of Dr. Crowder, the eminent oculist."

M. Bazin.—*Le Mouvement Médical* of November 16 says that this gentleman, "one of the most eminent of French physicians, and who in fact has not a rival in dermatology, will leave the Hôpital St. Louis at the end of the year (1872), neither the University nor the Faculty of Medicine having ever, at any time, had the sense (*le talent*) to appropriate one whose scientific reputation is universal. The conduct of the Faculty towards M. Bazin is one of the best arguments against its official policy, and against the ministers and deans who have been in authority for the last twenty years. Without in the least sharing in the fancy some people have for the erection of busts and statues of men more or less celebrated, we think we ought to announce that a subscription is open for the rendering of a compliment of this kind to M. Bazin."

Histological Laboratory.—The same journal announces the establishment, by an order dated October 21, of a laboratory of this kind in connection with the chair of "médecine expérimentale," under the directorship of M. L. Ranvier.

Well Merited.—The *British Medical Journal* for November 23 says, "A letter, containing a check for £120, has been received by Mr. Robert Arthur Simpson, the medical student whose active exertions in behalf of

his fellow-sufferers in the Kirkdale collision were recorded in a letter published in the *Times* of October 4. Mr. Gibson, the secretary of the Caledonian Company, who writes the letter, says, 'I take the opportunity to express to you the cordial thanks of the directors for the good service so humanely rendered by you to the poor sufferers on that sad Wednesday morning of the 2d of October, at Kirtlebridge.'"

POPULATION OF THE GLOBE.—There are on the globe 1,288,000,000 souls: of whom 360,000,000 are Caucasians; 522,000,000 are Mongolians; 190,000,000 are Ethiopians; 176,000,000 are Malayans; 1,000,000 are Indo-Americans. There are 8642 languages spoken, and 1000 religions. The yearly mortality of the globe is 42,043,000 persons. This is at the rate of 115,200 per day, 4800 per hour, 80 per minute. Among 10,000 persons, one arrives at the age of 100; one in 500 attains the age of 80; one in 100 to the age of 70. In 100 persons, 95 marry.

DUST RESPIRATORS FOR FACTORY OPERATIVES.—Good service is being done in England by calling attention to the great prevalence of lung-diseases among the operatives in dust-abounding factories, such as those where cotton, iron, china, flax, lime, etc. are worked. A simple and effective respirator, consisting of a light, flexible frame-work, lined with a filter of cotton-wool, has been put into the market by Grafton & Co., of Dublin. The protection afforded by this apparatus is effectual, and it is simple and cheap.

INDIGNATION MEETING.—A Parisian telegram of December 23 mentions a demonstration made by three thousand students on behalf of the microscopist Robin, whose name was stricken off the jury-list because of his professed atheism. One would suppose that exemption from such duty would be rather a favor, no matter upon what grounds it might be based.

M. HENRY DURANT, the founder of the International Society for the succor of those wounded in war, has been overtaken by misfortune and lost all his property. A committee has been formed for soliciting funds for his relief. The member in this country is Fulton Cutting, of New York, to whom any sums of money may be sent.

SIR THOMAS BROWNE maintained that every man at his birth was nine months old; and Coleridge has said, probably in reference to this, that "the history of a man for nine months preceding his birth would probably be more interesting and contain events of greater moment than all the threescore and ten years that follow it."

DR. HENRY BOWEN DORRANCE died on the 19th ult., aged 44. We believe he never engaged in the practice of medicine.

DR. JOSEPH BROOKFIELD, of this city, died on the 17th ult., aged 84 years.

MORTALITY OF PHILADELPHIA.—The interments reported at the Health Office for the week ending Dec. 28, 1872, were 231; 128 adults, and 103 minors. 5 were of bodies brought from the country; making the mortality of the city 226. Among the causes of death were:

Consumption of the Lungs	25
Other Diseases of the Respiratory Organs	35
Diseases of the Circulatory Apparatus	14
Diseases of the Brain and Nervous System	35
Diseases of the Digestive Apparatus	23
Zymotic Diseases (1 from Smallpox)	16
Typhoid Fever	12
Casualties	5
Cancer	4
Suicide	1
Debility (including "Inanition" and "Marasmus")	23
Intemperance	1
Malformation	3
Still-born	9
Old Age	11

(The interments reported for the week ending Dec. 30, 1871, were 532.)

THE meteorological record kept at the Pennsylvania Hospital was as follows:

	THERMOMETER.		BAROMETER. (2 P.M.)
	Max.	Min.	
Dec. 22	16.0°	5.0°	30.50 in.
" 23	32.0	17.0	30.20 in.
" 24	16.0	10.0	30.61 in.
" 25	18.5	6.0	30.55 in.
" 26	16.0	10.0	29.80 in. (Snow.)
" 27	19.5	10.5	30.05 in.
" 28	27.0	10.0	30.41 in.

OFFICIAL LIST

OF CHANGES OF STATIONS AND DUTIES OF OFFICERS OF THE MEDICAL DEPARTMENT U.S. ARMY, FROM DECEMBER 17, 1872, TO DECEMBER 23, 1872, INCLUSIVE.

BYRNE, C. C., SURGEON.—Granted leave of absence for twenty days. S. O. 243, Department of the East, Dec. 19, 1872.

MCCLELLAN, E., ASSISTANT-SURGEON.—Assigned to duty at Lebanon, Kentucky. S. O. 266, Department of the South, Dec. 14, 1872.

TILTON, H. R., ASSISTANT-SURGEON.—Assigned to duty as Post Surgeon at David's Island, N.Y. Harbor. S. O. 240, Department of the East, December 16, 1872.

HUBBARD, V. B., ASSISTANT-SURGEON.—Assigned to duty at Jackson Barracks, New Orleans, La. S. O. 193, Department of the Gulf, Dec. 10, 1872.

VICKERY, R. S., ASSISTANT-SURGEON.—Assigned to duty at Jackson Barracks, New Orleans, La. S. O. 196, Department of the Gulf, Dec. 14, 1872.

MACKIN, CHARLES, ASSISTANT-SURGEON.—Relieved from duty at Fort Macon, N.C., and assigned to duty at Columbia, S. C. S. O. 266, c. s., Department of the South.

MONROE, F. LE B., ASSISTANT-SURGEON.—Granted leave of absence for fifteen days, with permission to leave the limits of the Department. S. O. 265, Department of the South, Dec. 13, 1872.

MATTHEWS, W., ASSISTANT-SURGEON.—Assigned to temporary duty at Willett's Point, N.Y. Harbor. S. O. 243, c. s., Department of the East.

SATURDAY, JANUARY 11, 1873.

ORIGINAL COMMUNICATIONS.

A BRIEF REVIEW OF THE REPORTS ON SCARLET FEVER AND DIPHTHERIA PUBLISHED IN THE "TRANSACTIONS" OF THE MEDICAL SOCIETY OF THE STATE OF PENNSYLVANIA FOR 1871.

BY HIRAM CORSON, M.D.,
Maple Hill, Montgomery Co., Pa.

(Concluded from page 215.)

WE should have a positive, well-defined belief in regard to this *grave* condition, and select our measures of relief in accordance with it. This latter view is the one which I hold in relation to the early prostration of the vital forces in scarlet fever and in diphtheria. And now, believing that I can arouse this prostrate vital force only by acting on the nervous system, what shall I do? Of all the means of arousing the nervous system to action in the coma, or the tendency to coma, which characterizes grave cases of scarlet fever, I have never tried any equal to the *pouring of cold water* on the head. It has proved successful with me in many of the gravest cases of scarlet fever, in coma from erysipelas, and in two cases of deep stupor from poisonous doses of alcohol. I have scarcely a doubt that it would have succeeded in Dr. Suisher's cases, had he done it with a bold hand, without fear of the pale and prostrate condition of the patient, and not for a minute or two, but on and on till the brain was aroused and consciousness restored.

But let us return to Dr. Suisher's report. He says,—

"The disease subsided, and did not reappear till next February, when it occupied a large territory. It was of the anginose variety, and the throat-affection severe."

And now hear him:

"It was during the prevalence of this epidemic that I for the first time tried the use of ice internally and externally to the throat, and the result was highly satisfactory, producing effects equal to what its most sanguine advocates claim for it. Of over thirty cases, all recovered. *Three of them would not, I think, under any other treatment.* In connection with the ice I used other remedies, such as the cases required; but in several of them I attributed recovery to the ice persistently and regularly applied. In those cases of scarlatina in which the throat-affection predominates, *I believe it to be superior to any other treatment.* That it would have lessened the mortality in the other cases mentioned, I cannot believe."

And now allow me a word of explanation. Why was there not much throat-affection in the cases where the vital forces were so greatly prostrated? Because when the nervous system is affected deeply, as in shock from injury, or from poisons, or from sunstroke, local inflammations do not—nay, cannot—manifest themselves with any vigor, until the brain has been relieved. But if Dr. S. had relieved the brain from its torpor by pouring cold water upon the head, he would have seen the eruption glow on the skin, and the tonsils inflame and swell so as to demand the ice internally and externally, as in his latter cases. My heart warms towards Dr. Suisher for the advance he has already made, and the hope he has given me of better things yet to come.

Dr. L. H. Lenher, of Cumberland county, speaks of scarlet fever and diphtheria prevailing, but gives no clue to the treatment, nor percentage of deaths. In diphtheria he bleeds, and gives calomel and ipecacuanha for twenty-four or forty-eight hours, but in what quantity he does not say.

In Fayette county, Dr. Voorhees had ten cases in April and May. He used mild purgatives to regulate the bowels, veratrum viride to reduce the pulse, cold to the fauces, in the form of ice-water, or lumps of ice held in the mouth; and a saturated solution of chlorate of potash as a gargle. He has long since abandoned the use of the swab to the throat, considering its use fraught with disastrous consequences.

Dr. Sheller, of Lancaster county, "had about sixty cases of the mildest type, and only two deaths,—not quite four per cent." Treatment, "wash with warm water and soap every six hours,—chlorate of potash as a gargle." Thinks he "has been as successful with the warm water and soap as ever Dr. Corson has been with ice." Not if he lost two out of "sixty cases, nearly all of the mildest type." In my advocacy of the ice and cold-water treatment, I have special reference to the treatment of grave cases,—those cases which, under the common hot treatment, with bacon to the throat and lard smeared on the body, and caustic and chlorate of potash applied to the glands and mouth, sweep off whole families, and which physicians speak of as "cases in which no treatment is of any avail." Instead of losing two out of sixty mild cases, I would not expect to lose more out of sixty grave ones, *if seen early.*

Columbia county.—Dr. Craig had much of the disease in April, May, and June. Of his treatment, suffice it to say it was the treatment long in use,—calomel, Dover's powder, ipecac, chlorate of potash, tincture of iodine to the neck, and lard to the body. If violent, an emeto-cathartic. He sums up by saying,—

"I feel free to say that I derived more benefit from the chlorate of potash in the throat-difficulties than from any other remedy;"

and adds,—

"It is impossible to give a correct average of the mortality; but, owing to the mild form of the disease during the early part of the epidemic, I should judge that it was about eight or ten per cent. of the whole number treated."

I regret that this article is too long for insertion here. It is the old history of a trial of nearly every remedy used during the last half-century, and the results were too fatal to invite a trial of it hereafter. There must have been a dreadful mortality of the severe cases, to make eight or ten per cent. of the whole number, when the many cases were of the

mild form. How valueless the treatment must have been in the grave cases, may be readily imagined, when his most potent remedy was a solution of a few grains of chlorate of potash. I am truly sorry to criticise the doctor's treatment, but the interests of humanity demand that every vaunted treatment be examined and held up to the light without fear or favor.

Dr. Ziegler, of Lancaster county, reports forty cases of scarlet fever, and eighty-five of diphtheria; four of the former and eleven of the latter died. Treatment of scarlet fever, "mild cathartics, veratrum viride, chlorate of potash; externally, inunction with lard daily, with ice-water to allay thirst, gave the most effectual relief." Treatment for diphtheria the same, "but with ten to thirty drops of muriated tincture of iron added to the solution of chlorate of potash, every three hours." It was mainly the same treatment used by Dr. Craig, improved by the allowance of ice-water as drink, and the results were nearly the same in severe cases.

We all know that in an ordinary visitation of scarlet fever or diphtheria, not more than one-fourth of the cases would be of a grave type. And it is for these latter that our remedies should be efficient. Any nurse can manage the mild ones.

Dr. Treichler, of the same county, had, from June, 1870, to April, 1871, two hundred and forty-three cases, "in which applications were made to the false membrane with solid nitrate of silver, or with carbolic acid and glycerin. Externally, volatile liniment, unguentum cantharidis, sinapisms, turpentine, and old bacon."

In the name of science and an enlightened humanity, I protest against these dangerous external applications, which in thousands of cases have slain their victims. But let us proceed. "To allay the fever, veratrum viride and spirits of nitre; where the disease passed to the windpipe, used emetics, calomel, inhalations of lime, counter-irritants, warm bath, in fact, almost everything, without avail."

Is it not strange that in two hundred and forty-three cases, when nothing was of avail in twenty cases, some other treatment was not tried? Instead of the now rejected caustic to the throat, why did he not try ice, or ice-water, or ice-cream freely, and externally, instead of the useless bacon and the dangerous irritants and vesicatories, iced water or ice to the neck continuously, at the same time sponging the body with tepid, cool, or cold water, as the case might demand, instead of smearing it with lard? Those remedies have been found efficient hundreds of times in the gravest cases, and might at least have been tried, in those cases where the old remedies had, as he declares, proved of no avail.

Luzerne county was visited by scarlet fever "seldom evincing malignancy." In addition to well-known remedies, Dr. Crawford recommends sulphocarbolate of soda. In about thirty cases he relied almost exclusively upon it. To a child three years of age he gives from one and a half to three grains every two hours.

Mercer county.—"Scarlet fever prevailed," says Dr. Livingstone, "in the county for eighteen months past, with more malignant cases than are usual, and many *died early* in the disease." His treatment may be deduced from the following extract:

"I believe the profession satisfied on three points. First, early feeding; second, expectant plan—no medicine; third, no cathartics till the decline. No one has applied cold-water bath, or douche, or ice."

I cannot pass these delusions, harmless as they may seem to the author, without a word or two. When shall the early feeding come in, or the expectant plan show its power, in a case that suddenly begins with vomiting, in a few hours is followed by convulsions or a violently inflamed throat, and, unless saved by prompt and efficient measures, would be a corpse in less than forty-eight hours? Talk of early feeding, and expectant plan, when your child is struggling for life and demands instant relief! He who has seen a severe case of scarlet fever knows how great the peril, and will at once to the rescue.

Montgomery county.—Dr. Sargent writes:

"The ice treatment of scarlet fever is still a popular remedy, and growing rapidly in favor; and while our members do not have the same success that Dr. Corson claims, they acknowledge it a potent and efficient application and remedy."

Thank you, doctor, for your words of cheer, and let me assure you that when you wield the remedy with confidence you will reach the success which Dr. C. claims.

Northampton county.—Professor Traill Green says,—

"A mild and cooling treatment produced the most beneficial results; caustics and strong acids, applied by means of a sponge, too often produce an inflammation in the surrounding parts, which in the condition of the system pass into an unhealthy form, and the disturbance to the system, caused by the use of a remedy so unpleasant to the child, adds greatly to the danger of the disease."

These are wise words, and should not be forgotten; he adds,—

"It is far easier now than formerly to conduct the treatment in a cool room with cool drinks, and, when proper, with cold applications to the body of the patient."

Another physician in the same county reports "one hundred and sixty cases, of whom fourteen died." He used the ordinary remedies, and "tried the ice around the neck in some cases, and ice-water in others, without any good effect. Ice-water was tried in one case from the beginning, and was very comfortable and soothing to the patient, but was of no avail." Which latter clause means that though the ice-water soothed and comforted the child, yet it died. And this he thinks was a trial of the ice-treatment. What could he expect from a cloth dipped in ice-water and applied around the neck once in half an hour, as it probably was? In one minute it would be warm, and would need to be changed. Indeed, nothing but the *constant application of the ice itself* would be sufficient in a severe case. He also says,—

"In one of those congestive cases where delirium was present, the cold head-douche relieved the delirium, but the child died afterwards, of croup."

What an important gain, that by the cold douche he had relieved the brain! If then he had remembered what I have so often asserted, that as soon as the brain is relieved the throat-symptoms will manifest themselves more rapidly than before, and had applied ice externally to the neck and internally to the fauces, he would have stayed the inflammation, and have prevented extension to the windpipe. He further adds that

"Dr. A. K. Seem used the cold-water douche in two cases with success, where he believed any other treatment would have failed." And Dr. Seip, of Bath, informed him that "he cured two cases with ice, that would have terminated fatally under the ordinary remedies."

Valuable testimony in favor of the cold treatment.

Philadelphia.—Dr. Benjamin Lee says,—

"Scarlet fever prevailed to a greater extent than during any year since 1861, and was of a grave character, and, what is very unusual, was quite severe during all the intense heat of summer."

There were nine hundred and fifty-six deaths, and yet he makes not the slightest allusion to the treatment, which I deeply regret, as Dr. Lee himself is well qualified to speak on the subject, and the other physicians who had those cases under care are many of them among the most eminent men of the great city so renowned for its medical colleges. To them we have a right to look for practical medical instruction.

Schuylkill county.—Dr. Thompson says,—

"It is matter of regret that the mode of treatment adopted by physicians in the county could not be reported with its attending success. The fact is a lamentable one that what is styled the *usual treatment* is manifestly of an empirical character, apparently having no influence on the disease."

He then details the symptoms of a very severe case in which "the condition of the patient was alarming and danger of suffocation appeared imminent." He resolved to try the ice-treatment, of which trial he thus speaks:

"The ice was applied internally and externally as nearly after the plan of Dr. Corson as possible. On the morning visit I found the patient breathing much more easily, but with little or no improvement in the condition of the fauces. She complained of discomfort from the water dripping on the chest, but none from the ice on the throat, and expressed no desire to discontinue its use. *The relief experienced from the first was great.* The patient afterwards informed me that she thought she would have suffocated had not relief been obtained when I first saw her. The ice was applied without intermission until the symptoms were relieved."

The chlorate of potash was used, and once the throat was touched with nitrate of silver. He adds,—

"The relief from the ice was immediate and continuous. The patient convalesced finely, with no sequelæ."

Testimony like this, even if it stood alone, ought to warrant a trial of this treatment, when, at least, the old treatment is powerless to save.

Dr. McKibbin, of the same county, has given a detailed account of treatment of an epidemic of scarlet fever not of a severe type, which seems a mixture of the old or usual practice with the cold drinks, milk, and ice-cream of the new. "In two severe cases emetics of alum three or four times daily were very useful. Externally, lard and sweet oil to the neck, with flaxseed poultice if the swelling be extensive; also inunction of lard to the body;" but he has "long since abandoned the probang with its heavy charges, as well as the solid stick of nitrate of silver," and is "very indifferent about the use of gargles." In conclusion, he says,—

"With this simple treatment my success has been so great, compared with my former efforts in the disease, as to astonish and delight me."

When we call attention to the fact that the disease was not of a severe type, we can readily account for whatever success he had. I have thus passed in review the plans of treatment, and if I have sometimes criticised with severity the treatment adopted by some of the reporters, I beg of them to attribute it to no unkind feeling, no disrespect for their abilities, but to a perfect loathing of the old, heating, gargling, poulticing, blistering, greasing, routine system, applied indiscriminately to the grave as well as to the mild cases, and which in the latter has hastened the death of thousands.

ON THE IMPORTANCE OF AFFORDING SUPPORT TO THE CORNEA IN WOUNDS, ETC.

BY CHARLES B. NANCREDE, M.D.,

Assistant-Surgeon to the Protestant Episcopal Hospital; Assistant to the Eye-Department of the Philadelphia Dispensary, etc.

I WOULD preface these remarks by stating that they are, of course, not intended for the instruction of those who devote themselves professedly to ophthalmic surgery, but for the busy general practitioner, who is frequently the first to see the traumatic cases, and who has neither the opportunity nor the time to study up the newest and best methods of treating such injuries. To such a one, a short journal article, which he can spare the time to read, may prove instructive, and it may, I trust, be the means of saving some eyes.

That I am not exaggerating the sad results caused either by want of treatment, or, still worse, by the use of unscientific measures, any one who has had even a limited experience in eye-trouble will bear me out. These evils have been very forcibly impressed upon my mind by a number of cases that I have seen lately, either under my own charge, or at some one of the several eye-clinics with which I am connected. For instance, I have seen an extensive wound of the cornea, either side of which was at least 1.5‴ in extent, which, according to the statements of the friends of the patient,—and, from the treatment which had been pursued by the family physician, they must have been correct,—had not been recog-

nized, or, if it had, had not been thought worthy of anything beyond a simple collyrium. I recall another instance, where an extensive central corneal perforation was permitted to run its course without any treatment addressed to the perforation itself, until, when seen, operative interference only availed. Again I call to mind another, where, perforation impending, proper treatment was resorted to with the most satisfactory results; but, owing to the refractoriness of the patient, the treatment was discontinued, upon which the cornea rapidly gave way.

This last case will represent the course of many others which timely interference would have saved from the evils of perforation.

To these cases might be added many more; but enough has been said to show the importance of what I am urging,—a correct method of treatment. In addition to the practical ignorance of the proper means of avoiding the evils consequent upon the injuries under consideration, I am surprised to see how the subject is neglected in articles on the eye, in nearly all the recent works on general surgery.

Before indicating the proper method of treatment, let us examine nature's mode of repair in penetrating wounds or in perforating ulcers,—their results being identical. The first effect of any opening into the anterior chamber is, of course, the escape of the aqueous humor, which generally washes the iris into or against the wound. The crystalline lens, likewise, must necessarily come in contact with the cornea in every case where there is any extensive loss of aqueous, and is thus exposed to great risk of more or less loss of function from being coated with the effused lymph. From the evacuation of so much of its contents, the eyeball partially collapses, thus permitting the edges of the opening to come into contact by the flattening of the convex cornea.

Now, it may be said that this is only an evil; for the prolapsed iris, strangulated by the lips of the wound, produces by the irritation propagated inwards an increased intra-ocular tension; this tension only aggravating the prolapse. This is too true; but in another class of cases the result is far different. Thus, when the perforation is small, the iris, merely falling against the cornea, becomes coated with lymph and blocks up the opening, thus preventing the escape of the aqueous humor, and re-establishing the anterior chamber. This is what nature aims at.

In many cases the re-accumulation of the aqueous humor tears loose the iris, leaving the opening closed by the lymph only. Again, this restoration of the anterior chamber may only stretch the adhesions, leaving the pupil almost intact. A worse result is when the pupillary margin is included in the prolapse, and all access of light to the interior of the eye prevented. When the iris is not strangulated, nor irritated by exposure to the atmosphere and the contact of the lids, there is but little increased tension.

We thus see that nature endeavors to effect two things: first, to restore the anterior chamber, and thus keep the crystalline lens away from the cornea, where its capsule would become coated with lymph, causing one form of cataract; and, secondly, to prevent the admission of air, and cause the coaptation of the wound by the flattening of the cornea. The only possible means by which this can be effected is, as we have seen, by the prolapsed iris acting as a plug to stop the opening until sufficient lymph can be exuded and kept in the proper position to fill the gap. Unless this preliminary plugging takes place, the lymph will be washed away as it is exuded, and a fistula would result, as we so often see in salivary and lachrymal fistulæ.

Having seen how nature works in effecting a cure, what indications do we observe to guide *our* efforts in aiding her? Clearly, first, to afford some artificial support to take the place of the destroyed portion of cornea. Secondly, to decrease the intra-ocular tension, the tendency of which is to increase the prolapsus, and, by keeping the edges of the orifice apart, to prevent union from taking place. Thirdly, to keep the edges of the opening as nearly in contact as is possible.

I need only refer to the results of treatment to prove the importance of fulfilling the first indication. This indication likewise obtains as a prophylactic measure when perforation is imminent. The necessity of acting upon the second indication will readily be seen by observing the effects of straining in hernia, which aggravates the protrusion by producing increased abdominal tension. The value of the third needs no explanation, as it is a cardinal point in all surgery to coaptate wounds.

How these indications shall best be fulfilled it will now be my effort to explain. Again let us look to nature as our best instructor in this as in so many other instances. In all injuries of the cornea, more or less photophobia exists, causing a violent spasm of the orbicular muscle, and thus pressing the lids firmly against the ball. This may seem, at first sight, only an effort to exclude the light which irritates the retina, rendered hyperæsthetic by the reflected irritation of the ciliary nerves; but I think we are all too apt to take a superficial view of nature's action in disease, and thus to overlook her efforts to limit injury, from which we may often deduce valuable therapeutic indications. To me this spasm of the lids seems also an effort to afford a support to take the place of the destroyed portion of cornea, and without which the protrusion of the iris would occur with much more facility than it does. This is not the explanation of photophobia in all cases of disease where it exists, but I think that it obtains here. Still, nature's effort does not suffice; for the lids are yielding, only restraining in part the protrusion: so that we must supplement her by the use of the pressure-bandage.

When there is much discharge, we should first place a piece of linen, slightly greased, over the closed lids, as otherwise there will be difficulty in removing the dressing. Generally, we may omit this. The best material for the compress is fine charpie, or raw cotton when that cannot be obtained; for the bandage, a flannel roller, one and a half inches wide, and about three and a half yards in length, although an ordinary cotton one will do. The orbit must first be carefully packed with charpie, especially in the

hollows at the inner side of the eyeball, and beneath the supra-orbital ridge, until the padding is nearly at the same level as in the centre. The pressure should be quite uniform, and so exerted as to gently stretch the lids laterally, thus rendering the eye fixed. The bandage should then be applied in one of two ways. We may place the initial end of the roller midway between the jaw and the ear of the affected side, carry it obliquely over the compress to the back of the head, and thence to the starting-point, making gentle pressure; take a second turn, ascending more vertically, exerting firm compression, and, finally, use a third, not drawn too tightly, ending, if we see fit, with a circular around the temples to secure the whole. This is according to Von Graefe's directions. Another bandage, and the easiest one to apply, is as follows: Make a circular turn around the temples to secure the end, then descend obliquely across the back of the head beneath the ear of the affected side, thence across the cheek to the eye, making gentle pressure upon the compress, until the forehead is reached, when a reverse should be made. A circular turn should now be taken to secure the oblique one, and the previous turns repeated till two or more have been made over the compress. Care should be taken not to draw the circular turns too tightly, as doing so will increase the pressure of the oblique ones. Of course, in the case of the left eye, we must make the circular turns from left to right, so as to bring the obliques under the left ear, and *vice versâ* for the right eye. By this bandage, the first and third indications are fulfilled; for it affords an artificial support to take the place of the injured portion of cornea, and it also coaptates the edges of the orifice. In atropine we find the means of fulfilling the second; for it decidedly lessens the intra-ocular tension. Besides this, it exerts a powerful sedative effect upon the inflammation, and, by dilating the pupil, drags the iris away from the cornea. The strength of the solution used should be from gr. j to grs. ijss, aquæ f℥j, carefully instilled into the eye, upon the average, three times daily, care being taken to let none enter the mouth or nose. For infants and young children, a still weaker solution than either named above had better be tried at first, to ascertain the susceptibility of the patient, since I have known intense flushing of the whole surface, dizziness, etc., from the use of the strong solutions.

By the use of these two simple measures I have seen the most extensive wounds and perforating ulcers with large hernial protrusions heal, leaving, comparatively speaking, no deformity. For instance, the triangular flap-wound of the cornea, before referred to, although gaping and irregular when first seen, healed with hardly any perceptible alteration of the corneal curvature, and with no serious inflammatory consequences. In another case, not before cited, where there was a rupture at the sclero-corneal junction, extending into the sclerotic, of about 4‴ in extent, after the removal of a small portion of prolapsed iris the wound healed, so that had it not been for the different color of the cicatrix the scar would not have been noticed. I have likewise seen this treatment rapidly reduce extensive prolapse of the iris occurring as a sequel of gonorrhœal ophthalmia. What I would call attention to in this last case is, that the bandage was used soon after the sloughing had taken place, and before all the chemosis of the conjunctiva had passed away.

I think that many practitioners would have hesitated to increase the pressure on the sloughing cornea, since, in some forms of ulceration, dividing the external canthus to lessen the pressure has been recommended; but the sequel proved that I was right, since sufficient clear cornea was saved to have permitted an artificial pupil to be formed had the patient desired it. Of course, I do not maintain that all wounds and perforations will result as successfully as in the cases cited, for they have been chosen to show what is sometimes effected; but I do say that many a case of staphyloma corneæ necessitating removal of the eye, and many of the extensive central opacities with destruction of the pupillary opening, would have been avoided or lessened by the timely use of the treatment detailed above. As a prophylactic measure it is invaluable, by preventing perforation in ulcerations of the cornea, also when this *has* taken place, and in wounds, in preventing the protrusion of the iris. Wounds of the cornea are not uncommon; for almost every general practitioner sees them occasionally, and perforations are still more frequent, although often unobserved. It is not very unusual to see the cornea give way in phlyctenular ophthalmia, one of our commonest forms of eye-trouble, and is *the* sequel of gonorrhœal ophthalmia and ophthalmia neonatorum, both of which latter every physician will be called upon to treat.

In conclusion, I would urge most strongly the importance of really *seeing* the cornea in all the "sore eyes" of children where there is much photophobia, as there is then, probably, some corneal affection; and, if perforation has taken place or threatens, the use of the treatment recommended in this paper.

RUPTURE OF THE BICEPS FLEXOR CUBITI.

BY SAMUEL ASHHURST, M.D.,

of Philadelphia.

THE following case possessed considerable interest for me at the time of its occurrence, and from its rarity seems worthy of going upon record.

I. S., aged 35 years, was admitted into the Episcopal Hospital, Philadelphia, July 26, 1871, suffering from a scalp-wound. He could give no very clear account of the manner in which he had been injured, merely stating that he was thrown from his wagon while driving, but did not think he had been run over. The scalp-wound was dressed, and he was put to bed. The next morning (July 27) he complained of much soreness in his left arm, when, upon examination, a rupture of the belly of the biceps was at once apparent. On the anterior aspect of the arm there was a depression an inch and a half wide, into which the skin and subcutaneous tissues could be pressed to the depth of half

an inch, and the ends of the torn muscle could be felt as thick lumps. Handling the arm caused great pain. Flexion of the elbow could be performed partially, with difficulty and suffering. There was hardly any evidence of injury to the neighboring skin, further than slight ecchymosis, from which fact it seemed most likely that the rupture resulted from sudden and forcible muscular contraction rather than from the application of a crushing force, as at first sight supposed. Compresses were placed over the separated ends of the muscle, which were brought together by figure-of-eight turns of a bandage enclosing the whole extremity, and the limb placed in a sling.

On August 4 the bandage was removed, and, although a slight indentation in the muscular substance was apparent, the patient was able to move the elbow freely and without pain. On August 7 all tenderness had disappeared, and, the scalp-wound having united, he was discharged.

Samuel Cooper is the only one among the older English surgeons who refers to ruptured muscles, and he merely treats of rupture of the tendo Achillis. Palmer * says that rupture of the triceps extensor cubiti sometimes occurs; but he does not mention the biceps, though the object of his remark is to correct the statement made by Mr. Hunter, that the tendo Achillis is the only one liable to the injury under consideration. Druitt says that rupture of the biceps occurs, but gives no case; and Erichsen, treating of ruptured muscles in general, does not mention the biceps. Mr. South † reports a case which occurred in his own practice, in which a tear of the biceps took place near its lower tendon from contraction of its own fibres; but, having failed to take notes of the case at the time, he does not give many particulars. Dr. J. Mason Warren, in his "Surgical Observations," relates three cases in which the quadriceps extensor femoris was either partially or entirely torn near its tendon of insertion; but a life of active and extended practice, of which his book is the record, apparently failed to furnish such a case as I record above. Mr. Tatum ‡ gives a pretty full account of torn muscles and the treatment proper to adopt in such rare accidents; but among the cases cited by him there is none of ruptured biceps.

Boyer § says that most authors speak of muscular ruptures as possible, without giving any cases, and that we must therefore regard the accident as very rare. He gives two cases himself, neither of which, however, was of the biceps. Vidal ‖ speaks at some length of muscular rupture, but does not refer to the biceps.

In fact, the literature of the subject is extremely meagre, one or two cases being all that any one systematic treatise furnishes. M. Reydellet ¶ gives the largest number of cases I have found together; but of the eight cases quoted by him from various sources, in none was the biceps the injured muscle. A paper by J. Sédillot upon ruptured muscles is quoted by Gross, Erichsen, Tatum, and the French surgeons generally, but I have been unable to find the original article. In the *Journal Général* for July, 1817, Sédillot gives an abstract of his memoir, with Baron Percy's report upon it to the Academy; but, as no cases are given, I cannot say whether an instance of ruptured biceps was among those collected by him.

My case did not present all the symptoms enumerated by authors, the ecchymosis having been less and the recovery more rapid than I should have expected by the descriptions given. That the accident is a rare one is sufficiently proved by the fact that the solitary case I have been able to find, after a somewhat extended search, is the one quoted by South from memory. While rupture of other muscles may be serious, as in the case of ruptured psoas recorded by Boyer, which terminated in death, such an injury as I report is apparently as unimportant as it is rare, and can only be regarded in the light of a surgical curiosity.

FRACTURE OF VAULT AND BASE OF SKULL.

BY J. H. T. KING, M.D.,
Captain and Assistant-Surgeon, U.S.A.

THIS case may perhaps be worthy of record, as an example of fracture of the vault and base of the skull, without the usual symptoms of such injury.

At reveille on the morning of November 18, 1872, Private James S———, Troop F, Third U.S. Cavalry, was discovered in bed in a supposed state of intoxication, and taken to the guard-house.

At 3 P.M., being still insensible, he was conveyed to the post-hospital.

Upon examination, the following phenomena were observed.

The patient was lying perfectly comatose; integument cool, pulse slow and labored, optic nerves paralyzed, right pupil dilated, left contracted, breathing slow and deep, accompanied by that peculiar whiff at the corners of the mouth, symptomatic of compression of the brain. No odor of alcohol distinguishable.

Head carefully examined; no wound or depression whatever detected. Scalp altogether uninjured; no oozing of blood or cerebro-spinal fluid from either mouth, ears, or nose; no escape of blood into cellular tissue of orbit. A slight contusion on dorsal surface of left hand was the only one found anywhere.

All the information that could be obtained regarding the case was that this soldier, with several others, had been engaged the previous evening in a drunken fight with some civilians, at one of the wretched liquor-saloons beyond the limits of the garrison.

3 P.M.—Ordered hair to be cut short and ice applied over the head. ℞ Hydrargyri chloridi, gr. x, at once; sinapisms along the spine, hot bottles to feet, and an enema of castor oil and turpentine at once administered.

5 P.M.—Gradually becoming worse; ten grains of calomel again placed on tongue, and enema repeated.

A catheter was passed and about half a pint of normal urine drawn off.

8 P.M.—A few galvanic shocks through spine and diaphragm failed to rouse the patient in the least.

Nov. 19, 1872.—Died at 1.15 A.M.

Autopsy, nine hours after death. A well-developed, healthy subject. Rigor mortis commencing. No external marks of violence, except a slight contusion of left carpus.

On removing the brain-coverings, a large, hard clot of extravasated blood was found between the dura mater and the right parietal eminence. Weight of clot 4⅔ ounces, circular in form, and 3¾ inches in diameter. The vault of the cranium was ascertained to be fractured at this point, immediately over the clot, through its whole thickness of bone, yet the latter retained its proper level, being driven neither outwards nor inwards; the fracture was of that character usually described as a fissure, involving various bones, the principal break running perpendicularly downwards through the mastoid portion of temporal bone, to mastoid process; it also passed horizontally inwards, fracturing petrous portion of right temporal bone, transversely, at the eminence of the superior semicircular canal. This fissure crossed the grooves for posterior branches of the middle meningeal artery, and had torn these vessels, thus giving rise to extensive hemorrhage, and forming the clot.

The dura mater was much congested throughout.

Weight of encephalon 52½ ounces. Brain-membranes very vascular; no laceration of their substance.

Externally, corresponding to the fracture of right parietal bone, there was slight ecchymosis of sub-integumentary tissues of scalp, but no tumefaction or other pathognomonic sign of such a serious lesion. This was visible only on the internal surface of the pericranium.

Heart, lungs, liver, and abdominal viscera normal.

The cranial bones were ascertained to be very thin: indeed, at the seat of fracture only one-eighth of an inch in thickness.

This thinness of the bones has frequently been alluded to by surgical writers in medico-legal investigations; it is obviously a matter of important consideration. In the *Medical Times and Gazette*, London, October 26, 1872, R. Eaton Power, L.R.C.P., London, makes the following observations on a case where the calvarium was in this condition, and, as his remarks seem very apropos to this subject, I venture here to repeat them:

"A very slight blow indeed on the top of the head would have killed this man, entailing, perhaps, as the case might be, a verdict of murder or homicide, whereas the amount of force exerted might be such that no one could anticipate a fatal result. Such an idiosyncrasy should have some weight with a jury, and, I think, conveys a lesson that, no matter how evident the cause of death (*post hoc, propter hoc*) from injury, still a post-mortem examination should not be neglected."

FORT MCPHERSON, NEB., Dec. 10, 1872.

THE DISINFECTION OF ROOMS.—Dr. George Derby, Professor of Hygiene in Harvard University, writes to the *Boston Medical and Surgical Journal* of December 5 as follows:

"Among aerial disinfectants chlorine and sulphurous acid are most useful, but neither of these gases can be added to the air of a room in sufficient amounts to destroy the specific poison of smallpox without making the air irrespirable. Organic impurities of all kinds attach themselves to moist surfaces, and sulphurous acid gas seizes with avidity upon everything holding moisture. To completely disinfect a room, including its carpets, furniture, and wall-paper, close the doors, windows, and chimney; put from one to two pounds of brimstone (according to the size of the room) in an iron pot, pour over it a little alcohol, set it on fire, and leave the room for four hours. This process is injurious to the colors of many fabrics, and to gilded articles, and this injury corresponds in degree with the amount of moisture present in the room.

"When disinfection by sulphur fumes is impracticable, the next best thing to do is to wet the carpet, furniture, and walls with a strong solution of carbolic acid, one part in fifty of pure acid.

"Clothing which can be washed may be disinfected by boiling in water for one hour.

"Bedding and clothing which cannot be washed may be disinfected by exposure for four hours to dry heat at a temperature of 225° to 300° Fahr. This can be done in a large 'brick oven;' but every city should have attached to its hospital for infectious diseases an oven specially arranged for the purpose."

A CASE OF VAGINAL HERNIA (*Boston Medical and Surgical Journal*, Dec. 5, 1872).—Dr. Bruyne, of Sleydinge, Belgium, reports (*Ann. et Bull. de la Soc. de Méd. de Gand*) a case of this rare form of hernia. A woman was struck on the head by a falling ladder, with sufficient force to produce temporary unconsciousness. No unusual symptom was noticed immediately after the accident, but in the course of ten days she began to experience a sensation of weight in the hypogastric region, accompanied by a bearing-down feeling in the region of the womb. A digital examination led to the discovery of a tumor of considerable magnitude, situated in the vagina. This was at first taken for a prolapsed womb, but a more careful examination showed that the tumor was not a displaced womb, nor was it caused by a prolapse of the mucous membrane of the vagina. The nature of the swelling, its resistance, the facility with which it could be replaced, and the rapidity with which it returned as soon as the hand was withdrawn, all indicated that the tumor was caused by a prolapse of the intestine into the vaginal canal. Having settled upon this diagnosis, Dr. Bruyne proceeded to reduce the hernia. For this purpose pessaries of several patterns were introduced, but without affording the desired relief. A permanent reduction was finally effected by means of the air-bag of Gariel, but to enable the patient to retain the bag it was found necessary to distend it by means of water instead of air.

MOVABLE KIDNEYS (*Med. Times and Gazette*, Sept. 21, 1872).—Dr. Jago, in 1858, reported in the same journal "two cases of supposed movable kidney." To ascertain how far his diagnosis that these movable abdominal bodies were harmless might be justified by the future, he has recently made inquiries about the patients. The first rejoined her husband in Australia several years after the above date, and it is not improbable that she is still living. The other, though still carrying the "tumor," was, a few months since, in wonderful health and spirits, and almost oblivious of the movable body whose presence she had herself detected twenty-three years ago, and which at that time caused her much mental distress.

Dr. Jago, in his recent report, relates two more cases of this anomaly. "To sum up," he says, "the four examples of movable kidney I have met with: All the patients were women, and the organ always the right. The first case was complicated by excoriated os uteri and irritability of the bladder, which was exaggerated by pushing the kidney downwards; the third with menorrhagia and leucorrhœa. There were signs, symptoms, or history which raised the question of malignant disease in the first, second, and fourth cases. The second and fourth cases were victims of hysteria."

PHILADELPHIA
MEDICAL TIMES.
A WEEKLY JOURNAL OF
MEDICAL AND SURGICAL SCIENCE.

The Philadelphia Medical Times is an independent journal, devoted to no ends or interests whatever but those common to all who cultivate the science of medicine. Its columns are open to all those who wish to express their views on any subject coming within its legitimate sphere.

We invite contributions, reports of cases, notes and queries, medical news, and whatever may tend to increase the value of our pages.

All communications must bear the name of the sender (whether the name is to be published or not), and should be addressed to Editor Philadelphia Medical Times, care of the Publishers.

PUBLISHED EVERY SATURDAY BY
J. B. LIPPINCOTT & CO.,
715 and 717 Market St., Philadelphia, and 25 Bond St., New York.

SATURDAY, JANUARY 11, 1873.

EDITORIAL.

ANOTHER STATE INSANE HOSPITAL FOR PENNSYLVANIA.

WE have before us a memorial to the Legislature of this State, prepared by a committee of the State Medical Society, and signed by them, in favor of the erection of a new public hospital for the accommodation of the insane of Erie, Crawford, Mercer, Venango, Warren, McKean, Elk, Forrest, Cameron, and Clarion counties. The names appended to this memorial—John Curwen, James Ross, J. L. Stewart, F. F. Davis, and W. Varian—are a sufficient guarantee of the soundness of the object aimed at, which has also the endorsement, by formal vote, of the Board of Public Charities.

Some of the arguments in this paper are so cogent, and the facts adduced in their support so striking, in an economic point of view, that we feel called upon to place them before our readers:

"No accurate census of the insane has ever been taken in Pennsylvania, the number in the United States census of 1870 requiring correction in some important particulars; but assuming the number there given as the actual number, there will be 3895, or a proportion of one to every nine hundred and four of the population.

"The hospital provision in Pennsylvania, including those in the different almshouses in the counties where really they receive no treatment, is 2825, leaving over one thousand entirely unprovided for. What the accommodations for the insane in the county almshouses are can readily be ascertained from the report for 1871 of the Board of Public Charities; they have no medical treatment, except in case of some intercurrent bodily disease, and no means of proper exercise and recreation, and yet many recent cases are taken to those institutions and kept there, and in the great majority of cases without any effort being made to give them the benefit of medical treatment, and as a consequence they are soon added to the already large number of chronic insane requiring to be supported by the public. . . . . .

"It is a fact established by universal experience that the majority of the insane in any given hospital are derived from the section of country more immediately adjacent to that hospital, so that it may be regarded almost as an axiom, that a hospital should be placed as near as may be, convenience of access and supplies considered, to the centre of population of the district it is designed to accommodate. In the ten counties named above, the population, by the last United States census, was 303,731, which in the proportion stated above of one to every nine hundred and four of the population will give 336 insane now in the district to be provided for.

"But it has also been clearly established, by careful calculations of the admissions in existing institutions, that one in 1690 of the population becomes insane in each and every year, so that in the same population there will be within a fraction of 180 who will become insane in that district in each year, and who will need medical care and treatment. If that number have the requisite hygienic and medical treatment in the earliest stages of the disease, 144 will in all probability be restored, while 36 will remain insane or die. . . . . .

"Every person becoming insane deducts so much from the producing power of the community, and is to that extent an incumbrance or mortgage on the property and income of the Commonwealth, or some of its parts, collectively or individually, to the extent of the cost of his or her support so long as the insanity shall continue. The individual's estate pays, if it can; but, if not, the public must, for the body politic is the bondsman for every one in sickness and poverty to pay what he cannot. . . . . .

"The cost of keeping an insane person at home, in a poor-house or a jail, is not less than three dollars a week on the average, and this must be multiplied by as many weeks as the insanity shall continue. The average duration of life of an insane person, not cured, attacked between twenty and thirty, is 21.31 years; attacked between thirty and forty, is 20.64 years; attacked between forty and fifty, is 17.65 years: that is, an insane person, when taken near twenty to thirty years old, will, if not restored, live, on an average, 1118 weeks, and will cost $3354 for his support. Those from thirty to forty when taken, will live 1073 weeks, and cost $3219; and those who are from forty to fifty when taken, will live 717 weeks, and cost $2751.

"These are sums which the people must pay; they are debts incurred the moment the man becomes in-

sane, and are a mortgage on the public property until these patients are restored. This, however, is not all the cost of insanity neglected and uncured; the Commonwealth loses all the services of these men, all that they would have earned during a sane life if they were restored. The probable longevity or average time sane men will live after twenty to thirty years is 39.12 years; after thirty to forty, 32.76 years; and after forty to fifty it is 26.06 years. Then the public must not only pay the cost of supporting an uncured insane person, when between twenty to thirty years, for 1118 weeks, but lose his earnings for 2034 weeks. The earnings, of course, will vary with person, capacity, position, and circumstances. . . . . .

"Let us next consider the cost of restoration. For those whose disease was less than one year before admission, the period of restoration has been found, on calculation of returns, to have been somewhat over five months. But if taken earlier and treated as promptly as fever, pneumonia, etc., the time required for cure is much less. The cost of this restoration, even including interest on the hospital and all other expenses in our State institutions, will not exceed five dollars a week; that is, about $130 for each insane person restored. If taken early, eighty per cent. at least can be restored, and twenty per cent. will either die or remain insane for life.

"The recent cases of insanity are always more expensive to take care of, from the greater attention required, and their disposition to destroy clothing, furniture, and fixtures. The cost of the curative experiment must include both that paid for those who are curable, and for the attempt to restore the incurable, during an average period required to determine the question of their curability,—say two years,—or for such as are restored to power, $260.

"It must, however, be remembered that this estimate of the cost allows the whole expense of the hospital to be five dollars a week for each patient. In calculating the cost of a cure, we should only include the increased expense of support for this purpose over and above what must necessarily otherwise have been incurred. Whether they cure or attempt to cure or not, the public must pay three dollars a week for the patient's support, and the curative process costs only two dollars a week in addition, and only so much then should be charged to place and means of restoration. The cost then should be stated as $104 for each one restored. Taking the English calculations of the present worth of a laboring man at twenty-five, and adding the difference of earnings in this country, an annuity equal to the excess of his earnings over the cost of his support through his probable average life, thirty-nine years, can be bought for $1800. The present worth of the cost of his support, if insane, $156 a year, through his probable insane life, twenty-one years, will be $1834. Both these are lost, equal to $3634, if the man is attacked with insanity and not restored."

We believe an apology is hardly necessary for these somewhat extended extracts, when their importance is appreciated. What is true in one county or in one section of a State is true also, perhaps with some modification, in other counties or sections, or in other States. The general drift of the argument in regard to the economy of adequate public provision for the insane is certainly of equal force everywhere. It is highly important that the medical profession should be well informed on this question, and that they should be ready to use their influence to advance plans so conducive to the general good. This they can do with far more force if their arguments are based not merely upon humanitarian but upon well-established economic grounds.

THE CHILDREN'S HOUSE AT ATLANTIC CITY, N. J.

ATTENTION was called in our columns, in August last, to this excellent charity. We have received from Mr. James S. Whitney a report, drawn up by Dr. F. D. Castle, the physician in charge, of the cases treated during the summer of 1872. It appears from this that twenty-five children were inmates of the house, and one was treated elsewhere under its auspices. Of these, twenty-three derived very marked benefit, one died, one was sent to the city in a sinking condition, and one was discharged without visible improvement.

Of the cases treated, six were of anæmia, three of coxalgia, two of cholera infantum, two of ulcers, and one each of necrosis of tibia, caries of cervical vertebræ, marasmus (died), atrophy of leg, chronic diarrhœa, articular rheumatism, equino-varus, chorea, scrofulous disease of several joints, inflammation of knee, knock-knee with partial paralysis, paralysis, and disease of spine.

Dr. Castle says, "The treatment was mainly of a hygienic character: the patients were kept as much as possible in the open air; those who were able to bear it took sea-baths; others had salt-water baths in the house. Electricity was employed in those cases in which it was indicated. Iron was found useful as a tonic in many cases; and wine, cognac, opium, and various astringent and anodyne lotions were employed in those cases which called for their use."

It is in contemplation to extend, if possible, the operations of this most beneficial charity; and we heartily commend it to those of our readers who can influence contributions of money or supplies in its behalf. Donations may be sent to James S. Whitney, Esq., 1815 Vine Street.

CORRESPONDENCE.

FREY ON THE MICROSCOPE AND MICROSCOPICAL TECHNOLOGY.

To the Editor of the Philadelphia Medical Times:

I HAVE just finished reading the notice of "Frey on the Microscope" in your last number. Though often dissatisfied with the notices of books with which I am familiar, I have never before allowed myself to take public notice of them. In this instance, however, such palpable injustice has been done to a book of such deserved reputation, that, conscious that many readers will be debarred from purchasing a volume of a kind which has been inquired for by every student of medical microscopy who has come under my notice, I have felt called upon to do what I can to correct the erroneous impressions which must obtain from its perusal.

Long familiar with the volume in the original, I have many times said that if we could have the work of Frey in English we should then have the best book, which, in its fair consideration of all matters required by the beginner, would exactly answer our demands, while all other text-books, though excellent in many respects are deficient in others. Thus, the valuable work of Carpenter furnishes a very full account of the optics of the subject, and as much of the "technik" as is necessary for mounting objects of general interest, and in the department of natural history is the most complete exposition of histology available. But in the subject of medical microscopy and animal histology and pathology it is totally deficient. So with the equally valuable text-books of Beale, which, besides being somewhat unsystematic, only pretend to furnish aid to the clinical microscopist, while the subject of optics is untouched. In Frey, however, we have a sufficiently yet not too full exposition of the entire subject,—optics, "technik,"—the latter the most complete and *elementary* yet afforded us in English,—as much human histology, and nearly as much pathology as is required by the medical student and practitioner.

What I more particularly complain of in the notice are first, what may be termed "damning with faint praise," and second, including as "imperfections" and "deficiencies" what are really only omissions. Such as these are the statements with regard to instructions being couched in technical language, to the omission of any indications of the degree of amplification of histological drawings, the fact that the references are only to German instruments, the absence of any uniform standard for prices, measurements, etc., prices being given in thalers, francs, pounds, or dollars, and dimensions in millimetres, parts of a Paris line, or subdivisions of an English inch, without any attempt at reduction, and the less than scant justice done to the leading microscope dealers in Philadelphia. Again, the repetition of *four* wood-cuts in different parts of the volume is spoken of as an "ingenious and altogether economical device" to fictitiously augment a "seeming wealth of embellishment." Finally, the critic fears that "the novice who consults it as a guide in his elementary studies will often turn from its pages in disappointment and regret."

As to the indication of the degree of amplification employed, it certainly has its uses, and especially in papers containing an account of new observations, accompanied by drawings, is indispensable; but that its absence is a defect which will interfere with the utility of a text-book on the microscope no one can for a moment claim. Why a German author should be expected to make references to other than German microscopes, I cannot understand; and as to the reduction of millimetres to inches, and *vice versa*, while there is every reason that the latter should be done, I hope soon to see the day when the metric system will be that solely employed in all scientific work, and the sooner the student is familiarized with that to the exclusion of all others, the better for him and for science. Again, no one can be prouder of the Philadelphia makers and dealers than myself, but really why a professor in Zurich should take pains to make allusion to them rather than to those of any other American city, I cannot understand. I feel truly indebted to the translator for incorporating American microscopes in the price-list, and think it natural that he should indicate prices in the currency of the country in which the instruments are made; they generally have to be paid for in such currency, at any rate. Of the historical résumé of the American manufacture of lenses and stands by the translator I do not think our makers can complain. So far from the method of repeating illustrations, to the very limited extent to which it is here employed, being an "ingenious device" to augment "a seeming wealth of embellishment," it is one constantly employed by authors, and especially by Dr. Beale, greatly to the convenience of readers, who would otherwise be compelled to turn over many pages to compare a cut, when in this manner they have it on the same page with the text, and if 4 are subtracted from 343 it certainly does not so much detract from a "seeming wealth of embellishment" as to make it worthy of criticism. Moreover, the letter-press is not altered except in the case of Figs. 211 and 248, where the change is so slight as to make no practical difference. As to "technical language" which cannot be understood, I have looked in vain for it, and, so far from believing the novice will turn from its pages with "disappointment and regret," I believe he needs but to compare it with any book extant on the subject to be satisfied of its superiority as an elementary treatise.

The addition of Fenwick's method of detecting elastic tissue of the lung in sputum in cases of phthisis, and of drawings illustrating parasitic skin-diseases, would greatly add to the utility of the volume, and their absence may indeed be looked upon as defects, which should be corrected in a new edition.

Justice.

Dec. 14, 1872.

PROCEEDINGS OF SOCIETIES.

PHILADELPHIA COUNTY MEDICAL SOCIETY.

Dr. D. H. Agnew, President, in the chair.

A CONVERSATIONAL meeting was held November 27, 1872, at 8 o'clock P.M.

Dr. Dougherty, of Maryland, made the following remarks on a case which had recently come under his care:

Mr. D., aged 27 years, was taken with a violent pain and swelling in the scrotum, upon or about the 7th of October last. A few days after this, a calculus, a little smaller than an ordinary plum-seed, was extracted by means of the spoon point of a probe director from the urethra near the glans penis. The swelling of the scrotum continued to increase until the 13th of October, when he first saw him. During this time he passed urine with difficulty, but no examination of the urethra was made. On the 14th of October sloughing of the right side of the scrotum began to show itself. The sac was then opened, which discharged a small quantity of serum; this was undoubtedly urine that had escaped from a fistulous opening in the bulbous portion of the urethra. This was followed with some relief. On the morning of the 16th Dr. D. saw the patient in company with Dr. C. H. Ohr, and his attending physician, Dr. P. A. Healy. An attempt was made to pass the catheter, but the canal was found to be closed by another stone. It was then determined to remove the calculus by making an external incision, the obstruction being apparently anterior to the bulbous portion of the urethra. The patient was first placed under the influence of chloroform. An incision was made on the right side of the scrotum close to the median line, opening into the urethra upon a grooved director. A free discharge of thick, dark, very offensive pus followed the incision. After the largest stone had been extracted, the smallest was discovered and taken out. An attempt being now made to pass the catheter, still another stone was discovered impacted in the prostatic portion of the canal. It was found impossible to remove this until the index finger of the left hand was introduced, and the sac containing the stone enlarged by cutting with a sharp-pointed bistoury. This patient has convalesced very rapidly, the sloughing wound and fistulous openings being all well closed.

When he was seven years of age he suffered with total inability to void his urine for a period of forty-eight hours. His attending physician passed a catheter without discovering any stone. On this occasion the urine was ejected in a stream, as the patient expresses it, "as high as the ceiling, probably ten feet." When he was twelve or thirteen years of age, he fell astride of the stern-post of a boat, inflicting a bruise in the perineum, producing severe pain and swelling in the urethra. He could always pass his urine in a good stream. The only difference he noticed between himself and other persons was, "that it took him a little longer time, and towards the latter part of the performance the urine dribbled from him." He is a married man and the father of two children. The ejaculation of semen has always taken place without any impediment.

Dr. Washington L. Atlee emphasized the fact that, in the case mentioned by Dr. Dougherty, the man was married and the father of two children; one stone was impacted in the prostatic portion of the urethra closing up the outlet of the vesiculæ seminales, and the other two were in front of this, occupying the membranous portion. He could understand how the urine might be readily ejected through an extensible urethra by means of the muscular power of the bladder and abdominal walls, but ejaculation would be imperfect. His wife was eight months pregnant at the time of the operation, and his child was two years of age.

Dr. Benjamin Lee referred to a case, suggested by the topic of difficult micturition, which occurred in a little patient suffering from spinal caries. The child was of a strumous diathesis, if indeed she were not the subject, as he had some reason to suspect, of vaccinal syphilis. Being summoned in great haste, he found her writhing on the floor in extreme agony. The paroxysm had been induced by the attempt to pass water, and had been preceded by others equally violent. On examining the external genitals, a tumor half the size of a filbert was observed just above the meatus urinarius. Being white at one point, it was supposed to be an abscess, but it gave no sense of fluctuation, and on more careful examination proved to contain a mass of sebaceous matter of almost cretaceous hardness, as large as a pea, collected beneath the preputium clitoridis. With some little difficulty, owing to its adhesion to the inner surface of the prepuce, it was turned out with the scoop end of a grooved director, and after a few moments the child was able to urinate freely. The pressure of this concretion had evidently produced a complete occlusion of the meatus. About six months later she had a similar attack, which was relieved by the same measure. He had never seen a case reported in any treatise on children's diseases exactly similar, and was desirous to know whether any of the members had met with this condition.

Dr. H. H. Smith, whilst waiting for the hour of the special meeting, suggested that it might prove useful and interesting to hear the views of the members present in reference to a subject in which every one had felt an interest, if only from the inconvenience it had caused them by the additional daily labor of walking instead of driving to visit their patients. He thought physicians might advantageously give more attention to the diseases of the lower order of animals with benefit to the community and the relief of a part of creation on which depended so much of our comfort and pleasure. He had recently had the opportunity of inspecting many of the cases of the so-called "horse disease," and he had been much impressed by the culpable ignorance manifested by those who pretended to be skilful veterinary surgeons. From the observation of some eighty cases, Dr. Smith thought the disease was a blood disorder, dependent probably on sporules or germs floating in the atmosphere, which being inhaled produced first irritation and inflammation of the Schneiderian membrane, accompanied by serous, mucous, purulent, and at length by sanious discharge from the nostrils, followed by sympathetic irritation of the cervical lymphatic glands, then by enlarged tonsils and difficulty of swallowing, and by inflammation of the larynx and trachea, which in from fifteen to twenty-one days was liable to be followed by pneumonic or pleuritic effusion. Auscultation in bad cases showed marked hepatization of the lungs.

As the disorder progressed, the circulation showed marked symptoms of disorder, being at first languid, then febrile, then extremely depressed; death was preceded by serous infiltration of the connective tissue in various parts of the body, as well as by ecchymoses and bloody effusions beneath the skin and mucous membranes. In several instances these ecchymoses resembled those of scurvy, and were visible in the nostrils, lips, gums, and eyelids, as well as in blotches that could be felt though not seen, except as swellings or so-called "farcy buds" under the skin. Punctures in the swollen limbs gave exit to a large amount of serum tinged with bile. The bowels were generally constipated, though in two cases colliquative diarrhœa was present and proved rapidly fatal. In bad cases

the typhoid symptoms soon became marked, and prostration rapidly supervened on exercise. In many respects there seemed to be a resemblance to malignant or well-marked diphtheria in the human being.

Dr. Smith had not prescribed for any horse except his own and those of one or two friends, but had simply observed the cases in the practice of the veterinary practitioners. From this he was satisfied that the great point in the treatment was abundance of fresh air, warm clothing, with frictions, stimulation of skin, bandaging of the extremities, drachm doses of sweet spirits of nitre in water twice or three times a day, and light but highly nutritious food, as ground and scalded barley, scalded oats and bran; and when deglutition was difficult, oatmeal gruel or thick barley-water. When the pulse rose from 80 to 100 (the normal equine pulse averaging 35 to 45, and best felt in the facial artery as it passes over the lower jaw in front of the masseter muscle), the administration of stimulants, as a half-pint of whiskey in three quarts of gruel or barley-water.

Dr. Smith thought it was the duty of physicians to aid the community by diffusing sound information (when demanded) in reference to the diseases of the lower orders of animals. A medical friend of his was once enabled to save a patient a serious pecuniary loss by visiting and prescribing for a number of monkeys that were sick in a menagerie and were dying of diarrhœa and exhaustion. As they were young, teething was suspected, and on giving chloroform and lancing the gums, together with the administration of mistura cretæ, many were promptly relieved.

Dr. Atkinson said he had no confidence in the methods of treating the horse, so far as he had observed them in the recent epizoötic. He asked Dr. Smith in what doses his friend prescribed for the monkeys.

Dr. Smith said the ordinary dose of chalk mixture had been given. Much credit had been gained in the "horse disease" by homœopathic remedies, but, except as an expectant treatment in opposition to the polypharmacy of other horse practitioners, this plan had in his opinion done no good. Whilst the depression of aconite, belladonna, etc. was often injurious, arsenic in small doses, 3 to 5 grains, was a useful tonic; iron, gentian, and ginger were useful in convalescence.

Dr. L. K. Baldwin stated that he had seen one case in which there was a very offensive, black discharge from the bowels of the animal during a period of twenty-four hours before his death. Some authors on veterinary practice speak of a general inflammation of the bowels attending the later stages of the disease, giving rise to the offensive discharge spoken of.

Dr. Welch asked whether the animals had been well kept. He had heard the statement made by a gentleman from the country, that a donkey and a colt had escaped the disease while they were in the open air in the field, but when afterwards stabled they suffered.

Dr. J. R. Wells stated that, from observation of the disease among horses in his neighborhood, he was satisfied that many if not most of the cases proved fatal in consequence of the heavy dosing they received. The following prescription—viz.: ℞ Potass. nitrat. ℥iss, Sulph. ℥iss, Antimonii et Potass. tart. ℥iss; mix, to be given three times a day—was largely used by the owners of sick horses, procured by regular prescription from the veterinary surgeon, or upon the recommendation of a neighbor, who had probably gotten it from the daily papers or in some other way.

One gentleman who had lost two horses and had been giving this prescription, by direction of a doctor, as a tonic, was somewhat surprised when informed of the effect of such doses on the system.

The most successful treatment was careful usage, good feeding, and, if medicine became really necessary, a teaspoonful of powdered nitrate of potash, with from ten to fifteen drops of the tincture of aconite root, every two hours. Dr. Wells further stated in reference to this treatment, that when recommending it to the members of a horse company at the annual meeting, one farmer informed him that so successful had these remedies proved in the pleuro-pneumonia among the cows some time since, that his neighbor, a farmer with a large dairy in Merion, Montgomery county, who had lost half his stock, upon adopting it cured every case; and so confident was he of its power over the disease, that, although he still had some sick, he bought others and filled up his dairy again, and did not lose another case after that time.

Dr. Phelps stated that at the Schuylkill mines, horses that were brought out of the mines at night suffered from the disease. Those kept entirely within escaped. This protection was attributed to the explosion of gunpowder and gaseous emanations.

Dr. Agnew stated that horses confined for eight months within the mines had suffered.

Dr. W. L. Atlee said he had used his horses daily. His stable was fumigated with sulphurous acid three or four times a day. They had the disease slightly,—were late in getting it: he fed them soft feed, gave ten drops of the tincture of aconite, and one drachm of nitre three times a day, drove them moderately so as not to overheat them. He avoided wrapping up their throats with flannel or driving them with blankets, but was careful to blanket them every time he stopped

Dr. Grove said it had occurred to his mind upon several occasions, when seeing horses having anasarca following this disease, that their urine was quite likely to contain albumen, and desired to inquire if any gentleman present had ascertained whether such is the case.

Dr. Bunn said that in one case albumen was found in large amount.

Dr. Hamilton thought it was quite proper to spend a short time in giving expression to such views or modes of practice as might conduce to the alleviation of suffering and the safety of so noble and useful an animal as the horse. The prevalent ignorance in regard to the diseases and proper mode of treatment of domestic animals in general, is extreme; and it is in view of the improper and too often violent measures resorted to in many simple attacks of the recent epizoötic, as well as other diseases to which the horse is subject, and the senseless, inert practice pursued in the violent and dangerous cases, that we are well justified in the casual introduction of this subject upon the present occasion.

Rationally to treat the disease of an irrational animal is no easy task; yet precisely the contrary view is that which generally prevails even with the veterinary surgeon. If, in addition to the inherent difficulties pertaining to the cases under consideration, we call to mind the incompetency of a very large proportion of those who profess to be skilled in and practise the veterinary art, it is manifest that in attacks of a moderate kind the animal would fare best by judicious nursing and strict attention to his natural wants. In severe and dangerous diseases requiring prompt and active treatment, he believed it too often happened that the horse was lost from timidity in the adoption and delay in the employment of measures sufficiently active to meet the emergency of the case.

Dr. Madden, of Torquay, Eng., recommends, in *The Practitioner* for December, the inhalation of five-drop doses of nitrate of amyl for the relief of angina pectoris. He used it with success in his own person.

PATHOLOGICAL SOCIETY OF PHILADELPHIA.

THURSDAY, DECEMBER 12, 1872.

THE PRESIDENT, DR. J. H. HUTCHINSON, in the chair.

DR. CHARLES B. NANCREDE presented a piece, three-quarters of an inch long, of a carpet-needle, which he had removed from the os calcis of a boy nine years old, who had applied at the Episcopal Hospital for treatment. The bit of needle was imbedded in almost its entire length.

There was no formation of callus, nor, indeed, any evidence whatever of inflammation or even of irritation. Dr. Nancrede thought this interesting in connection with the suggestions with regard to the treatment of ununited fracture in which the perforation of the ends of the bone with pins and points of ivory was employed with a view to excite inflammation and the consequent formation of callus.

Dr. SAMUEL ASHHURST related a case which had recently come under his observation, in which a piece of glass half an inch long by one inch wide had entered the thigh over the tuberosity of the ischium four years and nine months before he removed it below the line of Poupart's ligament, coming through the adductor magnus muscle.

Dr. JAMES TYSON presented a specimen of *abscess of the liver* after *chronic dysentery*, with *extensive ulceration of the large intestine*, and a specimen of *horse-shoe kidney*, from the same patient, a woman aged forty-eight, who was admitted to the Philadelphia Hospital, December 6, in collapse, and died two days after admission. No history was obtained.

The liver was the seat of two large abscesses; one was in the superior portion of the right lobe, and a second was near the inferior surface of the left. There was also peritonitis.

Dr. Tyson also exhibited the *smooth white kidneys*, weighing jointly twenty-two and a half ounces, from a case of so-called chronic catarrhal nephritis.

Dr. J. EWING MEARS exhibited a *scapula* which had attached to its inferior angle and part of its posterior surface a large mass of supposed calcareous formation. The bone was found in an ancient sepulchral cave in Kona, Hawaii, S. I., by Dr. J. M. Whitney (dentist), and presented by him to the Pennsylvania College of Dental Surgery.

Dr. H. ALLEN read the report of the committee to whom was referred the section of femur from a case of rheumatoid arthritis, presented to the Society by Dr. H. C. Wood.

The specimen examined comprised a transverse section of about an inch in length of the upper third of the shaft of the left femur. In the thickness of the wall of the medullary space, in the periosteal markings, it presented a normal appearance. The position for the medullary canal, however, was found occupied by an abundant cancelli, the minute character of which did not depart from the typical condition found in the osseous system in health. The committee's examination of specimens in osteology has been unsuccessful in finding any similar appearance. In the absence of evidence educed by study of the medulla, the committee would consider the specimen as instancing a variation in the form of the medullary space of the femur within the limits of health.

No medical evidence appears to have been called for on the second trial of Stokes in New York; at least none is mentioned in the newspapers.

MEDICAL SOCIETY OF THE COUNTY OF ALBANY.

SEMI-MONTHLY MEETING, DEC. 17, 1872.

Reported by JAMES S. BAILEY, M D.

DR. ALBERT VAN DERVEER, PRESIDENT, in the chair.

THE President announced the death of Dr. John F. Crounse, and on motion the following were appointed a committee to prepare suitable resolutions: Drs. James S. Bailey, Joseph Lewi, and John M. Bigelow.

Dr. JOHN V. P. QUACKENBUSH read a paper on *hydrorrhœa*. Having defined the term as one applied to discharges of water occurring during the latter months of pregnancy which are not preceded or followed by uterine contractions, and which do not interfere with gestation, he proceeded to give the views which various authors entertain as to its nature.

The opinions as to the nature and seat of the *false waters* have been diverse. Boehmer supposed that they were contained between the chorion and the amnion; Mauriceau, that they came from the interior of the amnion; others, that it is an œdematous condition of the womb. Carl Braun, of Vienna, has designated two kinds of fluid accumulations: first, between the chorion and uterine walls; second, between the chorion and the amnion: to the former he has applied the term *hydrometra ascitica*.

The report of Prof. Doughty, of Augusta Medical College, Ga., was also considered. He speaks of a discharge from the vagina which appeared without cause in a patient in the fifth month of her fifth pregnancy. The discharge was abundant and unattended with pain. Rest and the recumbent position were advised, and the patient was cautioned against imprudence for fear of a miscarriage. The leakage continued, and became more copious at night when in the horizontal position than when walking about. In the seventh month of pregnancy she was seized in labor and delivered of a still-born child, the bag of waters not forming as usual, but being what is usually termed a dry labor. There proved to be present another child, and with this the labor was normal and there was a large accumulation of amniotic fluid. Dr. Quackenbush claimed from the history that this was not a case of hydrorrhœa, but a rupture of the membranes high up, which was evident from the escape of the water more freely while she was in the recumbent position. He then related a case as coming under hisown observation, which was as follows:

Mrs. B., in the seventh month of her fifth pregnancy, while walking in the street, felt a sudden gush of water, which she supposed to be from a rupture of the membranes. Upon advancing a step and on looking where she had stood, the walk was quite wet. She hastened home and sent for Dr. Quackenbush, who, upon careful examination, found no symptoms of labor. Rest was enjoined. She went on to full term, and was delivered naturally, the bag of waters forming as usual.

He stated that he had found on the fœtal surface of a placenta an accumulation of fluid resembling a cyst, due probably to a lack of transudation.

The same has been observed by Dr. James Whittaker. Dr. Quackenbush is of the opinion that this is the source of hydrorrhœa. The fluid continues to accumulate until the cyst reaches the edge of the placenta, when, from lack of support, it ruptures, and the fluid escapes between the chorion and uterine walls.

The views of Carl Braun that the fluid accumulated between the chorion and uterine walls he considered untenable, because of the lack of secreting surface or tissue, the placenta being the only source of the fluid. The *false waters* are of the same nature as the am-

niotic liquor. Specimens of perfect placentas were presented to illustrate his views.

A vote of thanks was offered to Dr. QUACKENBUSH for his instructive paper.

Dr. WILLIAM H. BAILEY moved that it be transmitted to the State Medical Society as a communication from the County Society. Carried.

Dr. SWINBURNE inquired whether liquor amnii was replaced after being discharged. Dr. QUACKENBUSH thought it impossible.

GLEANINGS FROM OUR EXCHANGES.

LOSTORFER'S SYPHILITIC CORPUSCLES.—[The great importance of this subject, and the attention which it has recently attracted, seem to warrant us in laying before our readers the following extracts from an article by Dr. F. B. Greenough, in the *Boston Medical and Surgical Journal* for Dec. 12.—ED.]

At the meeting of the Gesellschaft der Aerzte, held at Vienna on Jan. 29, 1872, Dr. Adolf Lostorfer stated that he had discovered a means by which blood coming from syphilitic persons could be distinguished from that of persons not affected with that disease. He had received from Dr. Stricker several specimens of blood, on microscopic slides, part of which were from syphilitic and part from healthy persons, and on the third, fourth, or at latest the sixth day, he had given the results of his examination, which with the exception of some cases where the specimen was in a condition to preclude any satisfactory examination, his diagnosis tallied with the record which had been kept of the sources from whence the blood came. A similar test to which he was put by Hebra resulted in the same way.

He explained his method of examination, which may be briefly described as follows: A drop of blood, obtained by a prick, was placed on a glass slide, and covered with a covering-glass. It was then placed in a receptacle, so arranged as to have the atmosphere kept moist. These preparations, examined with Hartnack's No. 10 immersion object-glass, and No. 3 ocular, for the first two days showed nothing abnormal, beyond some vibrios, bacteria, and some of the earliest germs of sarcinæ, but on the fourth or fifth day small shiny bodies appeared, on some of which was seen a small process. These increased both in size and number during the next few days, when some of them were as large as a shrivelled red corpuscle. The number of processes, also, had increased, some of which had a secondary process attached to them. On the eighth to the tenth day a vacuole could be seen forming in the centre of these bodies, which increased in size until it seemed to be bounded merely by a thin layer, shown by a double line. This seemed to be the limit of development. Various reagents were added to these preparations. When tested in this way on the first day, they shrivelled up into a dark, irregular mass, whereas, when tested later, on the sixth or eighth day, although they were somewhat affected and shrunk, the effect produced on them was markedly less.

For three months he had examined blood of non-syphilitic patients, some healthy and some affected with other diseases, and as in no case, except a syphilitic one, had he found these corpuscles, he considered himself justified in calling them syphilitic corpuscles.

He then read the records of thirteen cases, from which he drew the conclusion that the presence of these corpuscles was not limited to any period of the disease, but that they were found during all stages, from the primary lesion, before the appearance of any eruption, to the latest forms of the so-called tertiary manifestations.

Dr. Stricker gave the number of preparations of syphilitic and non-syphilitic blood that had been given to Lostorfer, amounting to fifty-nine, in all of which, with the exception of one set of twelve, the diagnosis, when given, corresponded with the facts. There were, however, some in this number from which he said that he could draw no conclusions, as the preparations were not in a condition to use. In the set of twelve above mentioned, no conclusions were arrived at; the temperature at which these examinations had been made was 12° to 15° C. In all these preparations, the non-syphilitic blood was taken from apparently healthy individuals.

At the meeting of the same society, held on February 9, Prof. Wedl briefly reviewed Lostorfer's claim, and gave the results of a series of investigations he himself had been carrying on. He (Wedl) had found corpuscles in blood corresponding to those described by Lostorfer, but was convinced that they were either small fat-cells, or the remnants of broken-down white corpuscles. He accounted for the presence of fat-cells in the specimens by supposing that when the skin was pricked, either by the pressure of the instrument or by squeezing the skin to bring out the blood, the contents of the sebaceous glands in the vicinity were emptied and mixed up with the blood. That these corpuscles were really fat-cells, was still further proved to him by the fact of his having made a fine oleaginous emulsion, and finding the exact counterpart of them in it under the microscope. He also claimed that the vacuoles mentioned by Lostorfer were the result of a process of decomposition, by which carbonate of ammonia was generated, to the action of which on the fat-cells the vacuoles must be attributed. He had not found it necessary to wait for some days before being able to see these bodies, as they could be seen immediately by simply washing away with distilled water the masses of red corpuscles which, for the first few days, fill the field and obstruct the sight.

This communication was followed by a spirited debate, in which Stricker and Lostorfer endeavored to overthrow the position taken by Wedl, *i.e.*, that the corpuscles described by Lostorfer were nothing but fat-cells.

Stricker insisted that the bodies studied by Wedl and those described by Lostorfer were not the same.

A committee, consisting of Rokitansky, Reichart, Karsten, Klob, Brücke, Billroth, Von Basch, and Auspitz, was appointed to investigate the subject.

At the meeting held February 16, this committee reported that they did not consider the subject a suitable one for an official investigation, and requested to be relieved from duty.

In the second number of the fourth year of the *Archives of Dermatology and Syphilis*, Dr. Stricker published an account of his researches on this subject.

The following deductions at which he arrived are logical and well drawn.

These bodies do not exist, at least of a size appreciable by the highest magnifying power we possess, in fresh blood. They are organic in their nature, and are slowly developed at a temperature of 10° C., and probably at a still lower degree of temperature would not develop at all. In a temperature of 20° to 25° C. their development goes on quite quickly, and at blood heat still more so. When they have reached their full growth, they remain without change for some days, even if they are brought in contact with water or moisture.

With regard to the origin of these bodies he does not attempt an explanation. They must, of course, either come from the blood itself or from the air; if the former is the case, they must either spring from small

cells or sporules so minute in size as not to be appreciable by our microscopes, or else be the result of spontaneous generation. If we assume that they come from the air, we might suppose them to be of the nature of bacteria, only we should have to assume that these bodies took a form of development hitherto unknown, when planted in certain kinds of blood.

Stricker's second series of investigations were made with the view of seeing whether these bodies were, as Lostorfer claims, only found in the blood of persons having syphilis, and his deduction on this point is unequivocally no. The fact of a syphilitic patient, in whose blood they had been found in great abundance, having had a severe attack of hæmoptysis, suggested to him the possibility of these corpuscles being in some way connected with a depressed and cachectic state of the system. The result of his researches in this direction was to find them in the blood of a patient with cancer of the stomach, in large quantities in two cases of tuberculosis, in a case of Bright's disease with a cardiac complication, and in an anæmic convalescent from smallpox.

In the *Berliner Klinische Wochenschrift* appeared an article by Dr. Köbner, of Breslau, giving the result of his investigations, and the deductions derived therefrom, which differ materially from Stricker's. Space does not permit of even an abstract of his work, but the following is his result:—he claims to have found bodies in the blood after more or less time, depending on the mode of treating the preparations as regards sealing them up air-tight or not, degree of temperature in which they were kept, etc., which correspond to the corpuscles described by Lostorfer, but he found them as well in blood of healthy and acutely sick persons as of syphilitic ones. He supposes these bodies to be what have been described by botanists and zoologists under the name of vacuoles. They are thought to be very small drops of water, less dense than the surrounding medium, and consequently refracting the light less, and enveloped by a thin wall of albuminoid matter, derived from the surrounding medium. These bodies have been the subject of a paper by Prof. Haidenhain, who calls them albumen-drops (Eiweisstropfen.)

Curious Freaks.—To the other cases of the kind on record may be added the following, recently reported to the Boston Society for Medical Improvement:

"Dr. Jackson exhibited a photograph of a collection of needles, three hundred in number, which had been removed from the body of an insane woman at the asylum in Utica, N.Y. The case was fully reported some time since in the *Journal of Insanity*. There was no history of her having introduced the needles into her body before her entrance to the hospital, and no performance of that kind was observed while she was there, but a few weeks after admission an inflammation of the breast developed, and at the place of pointing of the pus a needle was discharged, the first of the three hundred from various parts of the body, the limbs, the abdominal walls, the mammæ, etc.

"Dr. Jackson also showed a collection of needles which had a history similar to those just described. They were removed from the body of a negro woman of Nantucket, some years ago; no cause for the freak of their introduction having been assigned."

MISCELLANY.

A Remarkable Case,—A Young Man without any Liver, Stomach, and other Essentials (from the Pottstown, Pa., *Ledger*).—"A very unusual and wonderful phenomenon was found within the body of William Millaur, aged about nineteen years, son of Mr. Joseph Millaur, of Cedarville, North Coventry township, Chester county, who died on Monday morning, December 9. The deceased has been afflicted for several years with curvature of the spine, enlarged spleen and liver. Ascites, or abdominal dropsy, set in about eight months ago, as the result of the enlargement of the liver and spleen, interfering with the proper functions of the body, gradually increasing until his death.

"The case was under charge of several physicians of this vicinity, since he was first afflicted. Dr. J. Davis, who has been his attending physician for several months past, performed a post-mortem examination on Wednesday last, in the presence of several persons, and, strange to relate, after having drawn about eight gallons of dark-colored serous fluid from the abdomen, found that the liver, spleen, kidneys, stomach, and bowels were completely absorbed, without leaving any portion of them remaining,—nothing being found in the abdomen but a portion of the omentum, and the serous fluid. How long this had been the case we are unable to say, but certainly it could not have been long."

Government Medical Aid for the Families of Army Officers and Enlisted Men.—We find the following among the telegraphic news from Washington published in the *Evening Bulletin* of January 4: "Some time since, the Surgeon-General issued an order depriving the families of army officers and enlisted men in Washington of gratuitous medical attendance and medicines, heretofore furnished by the Surgeon-General and his assistants, and confining such attendance and medical supplies to officers and enlisted men personally. The officers, after considerable difficulty, succeeded in getting their families relieved from the operation of the order of the Surgeon-General, but the prohibition still continues with reference to the families of enlisted men. As these men comprise what are known as the general-service clerks of the War Department, a body whose expenses are necessarily the same, while their pay is very much less than that of civilian clerks of the lowest grade, the injustice, or unfairness, to say the least, is apparent. The physicians employed by the Surgeon-General as attending or contract-surgeons have full privilege of private practice, and, whether so intended or not, the order inures directly to their benefit, as the five hundred or more enlisted men, whose families were accustomed to their service, prefer their attendance. An effort is being made to have the order of the Surgeon-General rescinded."

Gray Hair in Fashion.—A New York fashion-writer says, "The number of our prematurely gray young women on the streets, dressed in the height of fashion, and stylish, attracts attention. The hair is not powdered or frosted, but is really gray. One would hardly credit the fact, but a fact it is, that a chemical process is resorted to to bleach the hair white. The

reign of the blonde is over, and the old term "tow-head" passes from room to room. Golden locks are at a discount. Raven tresses are vulgar, and snowy hair is the style. The highest-priced wigs are gray, and not black or auburn. Such is the tyranny of fashion that young girls with black and auburn hair are crazy to have a bleached head."

A Labor-Saving Device.—Hofrath Matzler (*Jenaisches Archiv f. Geburtsh.*, u. G. M. Redslob, Diss. de Hebræis obstetricantibus, Lips., 1835, p. 11) once encountered in a village an obstetrical chair which owed its construction to the inventive genius of a poor carpenter, who had substituted this inanimate support for the living chair, the *rôle* he always had to play himself. His wife always maintained that she was delivered easiest when seated upon his extended limbs; gradually his reputation for proficiency in this art extended through the village, and pretty soon there was not a woman in the place who would be delivered in any other way than upon his knees. He grew weary of this business in time, and devised the chair mentioned, for his relief. "Yes," he said, "I would have enough to do, if I had to let every cow in the country calve upon my lap." This narrative shows clearly enough how in Solinger's day certain persons were selected to officiate as "*Schoot-steers.*" It is highly probable also that the obstetric chair had its origin in this way.

Mr. Holmes Coote, the anatomist and surgeon, long connected with St. Bartholemew's Hospital, London, has been suffering from general paralysis for some time past, and is wholly disabled from professional life. He is, unfortunately, in very narrow circumstances. His son, as well as the son of Mr. Baker Brown, will apply for admission to the Royal Medical Benevolent College at the next election.

The Ex-Emperor of the French.—Telegraphic advices to the daily papers announce that on January 2 the ex-emperor was operated on for stone by Sir Henry Thompson, in London. It is not mentioned whether it was lithotrity or lithotomy that was performed; but the symptoms so far are reported as favorable.

Valuable Prize.—The *British Medical Journal* of December 14 says "the Riberi triennial prize of 20,000 *lire* (£800) has been awarded to Dr. Giuseppe Corradi, director of the surgical clinic at Florence, for four works on the Diseases of the Genito-Urinary Organs, three of which are as yet unpublished."

New Journal.—The same periodical mentions that a new monthly journal, under the name of *Il Galvani*, specially devoted to electro-therapeutics, is to be published at Urbino, in Italy, this year.

Appreciated Services.—*The Clinic* says that Prof. Pitha, of Vienna, recently received a fee of $50,000 on the recovery of the only son of Baron Tedesco, a millionaire of that city. The boy was twenty-three days unconscious. Pitha's assistant also received a large sum of money.

Dr. M. M. Levis, of this city, died on the 27th ult., at the advanced age of 77. He had for many years an extensive practice in the upper part of the city, where he was well known and highly esteemed. He was the father of Dr. Richard J. Levis.

A Singular Death.—A man named Heidenberg, a glazier, is said to have been snowballed to death in New York on New Year's day.

M. Pouchet, well known by his researches and writings on the subject of spontaneous generation, died in Paris early in December.

Mr. John A. Brown, the munificent donor of $300,000 to the Presbyterian Hospital of Philadelphia, died on the 31st ult., aged 85.

Mortality of Philadelphia.—The interments reported at the Health Office for the week ending Jan. 4, 1873, were 385; 237 adults, and 148 minors. 14 were of bodies brought from the country; making the mortality of the city 371. Among the causes of death were:

Consumption of the Lungs	53
Other Diseases of the Respiratory Organs	79
Diseases of the Circulatory Apparatus	24
Diseases of the Brain and Nervous System	52
Diseases of the Digestive Apparatus	21
Zymotic Diseases	18
Typhoid Fever	5
Casualties	7
Cancer	8
Suicide	1
Exposure	4
Debility (including "Inanition" and "Marasmus")	38
Still-born	20
Old Age	19

(The interments reported for the week ending Jan. 6, 1872, were 545.)

The meteorological record kept at the Pennsylvania Hospital was as follows:

	Thermometer. Max.	Min.	Barometer. (2 P.M.)
Dec. 29, 1872	35.0°	20.0°	30.50 in.
" 30 . .	30.0	15.0	30.67 in.
" 31 . .	39.0	30.0	30.28 in.
Jan. 1, 1873	32.0	28 0	30.51 in.
" 2 . .	34.0	27.0	30.44 in.
" 3 . .	46.5	37.0	29.97 in.
" 4 . .	44.0	32.5	30.33 in.

The mean temperature of the month of December was 28.22°; that of the year 1872, 54.66°; rain-fall for the year, 51.117 inches.

OFFICIAL LIST

OF CHANGES OF STATIONS AND DUTIES OF OFFICERS OF THE MEDICAL DEPARTMENT U.S. ARMY, FROM DECEMBER 24, 1872, TO DECEMBER 30, 1872, INCLUSIVE.

Phillips, H. J., Assistant-Surgeon.—Granted leave of absence for thirty days, on Surgeon's Certificate of Disability. S. O. 230, Military Division of the Pacific, Dec. 12, 1872.

Munn, C. E., Assistant-Surgeon.—Assigned to duty at Fort Adams, R.I. S. O. 245, Department of the East, Dec. 23, 1872.

SATURDAY, JANUARY 18, 1873.

ORIGINAL LECTURES.

CLINICAL LECTURE
ON A CASE OF EXOPHTHALMIC GOITRE.

BY J. FORSYTH MEIGS, M.D.,
Attending Physician to the Pennsylvania Hospital.

Delivered October 12, 1872.

GENTLEMEN,—The patient you see before you I would not have brought here but with her own full consent. She is the subject of a rare affection, and I was anxious you should have an opportunity of seeing this example of the disease, but, as it is one which is injuriously influenced, in my opinion, by mental, or I would rather say emotional, agitations, I repeat that I should not have brought her here before this large class but with her own consent. I told her yesterday, in the ward, that her disease was a rare and a very interesting one, and that I wished the young men who were endeavoring to prepare themselves for the business of the physician might see her. "I will take you for a short time before the class," I said, "if you will go willingly, and if you will promise me not to allow yourself to be agitated. I will keep you there but a short time, and you will render the science of medicine a good service, and do yourself no harm, if you go willingly, and keep yourself calm and still." At first she thought she could not go. I said, "Think over it, and if, tomorrow, you make up your mind to go, I shall be very much obliged to you, and you will receive no harm from it."

I took this course in order to save her from the moral disturbance which would have followed any peremptory or unexpected exposure of her case before this large class.

You will please to observe the peculiar expression of the face. The complexion is pallid, not white or semi-transparent as it is sometimes in anæmia, but it is pale; she looks tired, and there is a rather fixed appearance about the muscles of the face, as though she had waited, and were still waiting, for some hope deferred. She has learned to wait for a recovery. Her eyeballs protrude much more than usual; they look large, and are covered by the eyelids to a smaller extent than they are in the healthy face. Her eyes look, as I once heard a very clever lawyer of this city say of his own child, as though they were looking over into next week. She can close the eyelids over the balls when she tries, as you may see now, when I ask her to shut her eyes, but it seems to require more effort than is quite natural. In some of these cases, such is the protrusion of the eyeballs that the patient cannot quite close the lids, and thus the eye sometimes suffers from exposure to the air and dust.

When I uncover the neck, you see that she has a goitrous enlargement of the thyroid gland. This condition affects the right half of the gland more than the left, and yet the enlargement is considerably less than it was two months ago, when she entered the hospital.

Observe the action of the heart. It is beating 132 times in the minute. Its impulse is extended over a larger space than natural, and it has a peculiar, rapid, sudden, *staccato* beat. The apex-beat is below and on a line with the nipple, and therefore is carried an inch farther to the left, and somewhat lower, than it ought to be. On auscultation the two sounds are distinct, clearer and louder than usual, and there is a soft blowing systolic murmur heard in the second left intercostal space, at the point where the pulmonary artery approaches closely to the walls of the chest. This is a non-organic or anæmic murmur. I heard it yesterday in the ward, with Cammann's stethoscope, and when the heart was more quiet and acting less frequently than now, distinctly.

You can see that the carotids are beating with more force and over a larger space than usual, and when I apply a finger on one side of the enlarged gland, and the thumb on the other, over the inferior thyroid arteries, I feel their pulsations very forcibly, and I find that every diastole of these arteries is attended by a thrill or purring tremor,—the *frémissement cataire* of the French. The thrill is very distinct and strong, and when the stethoscope is placed over these vessels there is a loud rushing murmur with every contraction of the heart.

Protruding eyeballs, enlarged thyroid gland, rapid, quick, and throbbing heart, unusual pulsation of the carotids, enlarged and thrilling inferior thyroid arteries, anæmia, general debility, an indescribable feeling of general nervousness or distress,—these are the prominent features of the case; and this group of morbid phenomena constitute the disease called Basedow's or Graves's disease, exophthalmos, or exophthalmic goitre; and thus the diagnosis is made.

I will now send the patient away, as I do not care to expose her to the excitement of this scene any longer than is really necessary, and I will read you the notes of the case:

Mary McC., æt. 25, single, and by occupation a laundress, was admitted August 10, 1872.

Her general health has always been excellent, but for some time she has been working very hard. For six months previous to the first appearance of her malady she suffered frequently from severe headaches, but she had no mental disturbance of any kind.

In the spring of 1871 her friends observed a sudden protrusion of the eyeballs, and soon after she noticed a burning and smarting sensation in her eyes, and that her heart beat more violently than usual. She feels confident that when the protrusion of the eyes first appeared there was no enlargement of the thyroid gland. The goitre did not show itself until October, 1871.

On admission, the appearance presented by the patient was very characteristic of the disease from which she suffered. The eyeballs protruded greatly; the thyroid gland was large and pulsated visibly, and the action of the heart was frequent and violent. On placing the hand over the goitre, a marked thrill was felt in the inferior thyroid arteries. A soft murmur was heard at the

pulmonic orifice, but no other abnormal cardiac sound was detected.

There was no excessive flushing of the face, and her general condition was good. She is more readily fatigued than formerly, but never feels giddy, and sleeps well. Her memory is good, and her mental condition unchanged.

She was placed in bed, with directions to remain there, and given digitaline gr. $\frac{1}{60}$ three times a day, with a pill consisting of quiniæ sulph. gr. j, pil. ferri carb. gr. ij, ext. belladonnæ gr. $\frac{1}{12}$, three times a day. On August 19, her condition being unchanged, she was ordered Niemeyer's pill: ext. opii gr. $\frac{1}{8}$, digitalis gr. ss., sulph. quiniæ gr. j., t. d., and the other medicine stopped.

August 28.—Goitre seems smaller; pulse 96.

Sept. 2.—Eyes more prominent, and pulse 120 per minute, full and bounding. There is nothing to account for this change in her condition. She has had no worry or excitement, and she denies having been out of bed. Ordered a belladonna plaster over præcordia, and the compound gentian mixture three times a day.

Sept. 5.—Pulse 114.

After this the pulse gradually diminished in frequency until Sept. 15, when it had fallen to 72 per minute. The eyes protruded less, and the thyroid was much smaller.

Oct. 11.—Condition very much the same as when last note was made.

Now, gentlemen, the pathology of this disorder is not clearly understood. That it is usually connected with anæmia is true; but that anæmia is the only disorder I cannot believe, since I see so many worse anæmias without any such developments as you see here.

The most reasonable scientific explanation of these symptoms that I know of is the one which assumes that there is some loss of power in the controlling influence of the vaso-motor nerves, which allows the heart to act with unusual force and frequency, and which permits the arteries of the neck to undergo, for the time being, a larger diastole than is their law in the healthy state. Niemeyer supposes that there is a sub-paralytic condition of the vessels of the muscles of the heart. I have seen in my private practice four very severe cases of this disease, one of which proved eventually fatal, in all of which the patients (women) had undergone great agitation of the mind, or, I had better say, of the emotions. One had been dreadfully hysterical in early life from a love-affair. Her attachment to a young gentleman was opposed by her parents, and she was very ill with a long train of hysteric phenomena in consequence. Finally their consent to her marriage was obtained, and she recovered, but the shock left her nervous and unsettled, and, after the birth of a second child, she had an attack of this disease, with all the phenomena above described, which lasted nine months, during which she almost died daily,—I mean in her own imagination,—but finally, under iron, digitalis, opium, nutritious food, prolonged rest, and correct moral management, including assurances of final recovery, she got entirely well.

Another case was that of a young married woman with two children, whose husband was not successful in business, and who, being obliged to live in a state of irritating dependence on some of his relations, became unhappy, unsettled, despondent. Her heart began to palpitate, its action became frequent, and she finally developed this disease. She left the city after a time, improved temporarily, then got worse, and died, after three years, of dilated heart.

A third case occurred in a young woman who was most unhappily married. Her husband proved a rascal; had to flee the city. After several years of anxious doubt and suspense, attended with many psychological irritations, she obtained a divorce. I believe she formed another attachment, and had a severe and well-marked attack of this disease, of which she finally recovered, to be attacked a year later with diabetes mellitus, of which she died.

The fourth case was that of a widow, forty years of age. In her early married life her husband had been in a prosperous business; she had four children, and was happy, contented, and in excellent health. Her husband died of consumption, and left her with a very moderate, indeed an insufficient, income. She had to bring up her family on this small income; and then one of her children gave her a great deal of anxiety, and, after several years of these carking cares and this moral pressure, she developed this disease. She was attacked in October, 1868, and soon had all the signs you have seen in the patient I showed you. I kept her for eight months on her bed, and in June, 1869, sent her to the country. She was then much better, but not well. In July of 1869 she went to the seashore, took too much exercise, and became worse again. In September, 1869, she returned to Philadelphia, and I again ordered her to bed. She improved very much, and in December of that year was able to be up and about the house without injury. She continued slowly to improve, and in November, 1870, went to Richmond, Virginia, where she remained for six months, returning to this city in May, 1871, in very fair health. She passed the summer of 1871 at Media, near this city, where she was very well. Since then she has been well, except that she finds that her heart beats too much when she is fatigued or worried. I saw her a few days ago, weighing 160 pounds, a fine, handsome, healthy-looking woman. The heart is quiet, and exhibits no murmur whatever; the carotids beat quietly, the inferior thyroids have ceased to pulsate too strongly or to thrill, and the thyroid gland has returned to its natural size. She told me that her eyes would still project a little when any worry has occurred to make her heart beat too much. She took digitaline all the while she was under treatment, with a pill of belladonna, quinia, and iron; her diet was nutritious and digestible, and everything was done to keep up hope and cheerfulness. I told her all through that she ought to get well, and she has got well.

I have seen some four other cases, three of which were in this hospital, and one about which I was consulted in private practice. One of the cases occurring in this house died; the others I lost sight of.

I have tried to discover some moral or emotional cause in the young woman you have just seen, but she denies the existence of any worry or fret. Whether

she speaks candidly I do not know. We cannot get at the whole truth in a hospital as we can in private practice, where we know the whole family history.

I must say that I cannot but think that, in the four cases I have rapidly detailed to you, the psychological condition had something to do with the disease. If so, how do worry and moral agitations act to cause this curious disease? If you will look into Claude Bernard's charming work, "Leçons sur les Propriétés des Tissus Vivants" (Paris, 1866), in the last chapter—that on the physiology of the heart and its relations with the brain—you will find some curious facts and explanations which I think bear upon these cases. At all events, his thoughts and descriptions appear to me to give some clue to the manner in which my patients may have had their circulation disturbed by the state of psychological unrest in which they had so long lived.

Bernard remarks that, for the physiologist, the heart is the central organ of the circulation, and for that reason an organ essential to life. But the word heart, he says, has passed into the language also of the poet, the romance-writer, and the man of the world, with other meanings. The heart, for these, is no longer a living motor, driving the blood into all parts of our body; it is also the seat and emblem of the noblest and purest sentiments of the soul.

He shows that the heart acts by a power of its own, and that its connections with the brain through the pneumogastrics are but to place it in proper relation with that great nerve-centre. He asserts that, so long as the nerves of the heart are not excited, the organ beats and preserves its natural functions, but that when its nerves are excited, naturally or artificially, it becomes relaxed or falls into a state of repose. When a galvanic current is applied to these cardiac nerves, the effect produced depends upon the strength of the current. When powerful, the heart ceases to beat; when more gentle, the action of the organ is for the moment arrested or impeded, to be followed soon by more rapid and energetic contractions.

It is impossible for me to give you all or nearly all of his statements and explanations, for the paper is quite a long one, but it leads to the conclusion that the common language of life is founded on a true physiological foundation. When one says that love makes the heart beat, or that one loves with all his heart, the language is not merely a poetic fervor, it is a physiological reality. "When a woman," he says, "hears some tender words which arouse in her a soft emotion, the heart feels the impulse instantly, before either reason or reflection. The sentiment begins to show itself by a slight arrest of the heart, imperceptible to all but the physiologist; the heart, pricked by the nervous impression, reacts in palpitations which make it bound and beat more strongly in the chest, and drive the blood strongly to the brain, whence come the heightened color of the face and the expression indicative of the happiness experienced." When it is said that the heart is broken by grief, substantive phenomena have occurred in the action of the heart. Has the painful impression been too sudden, the heart has been arrested; blood no longer reaches the brain, and syncope or nervous crises are the result. There is good reason, therefore, that tragic events should be communicated to those who have to meet them only with care and management. When it is said that the heart is full, after we have suffered long from grief or other painful emotions, this also answers to certain peculiar physiological conditions of the organ. Long-continued saddening emotions become incapable of arresting the action of the heart, fatigue and weary it, retard its pulsations, prolong its diastole, and cause a feeling of fulness and constriction in the præcordial region.

It is to this latter condition that I wish particularly to call your attention. May it not be that, in some of the cases I have cited to you, in which certainly the disease we are studying followed upon prolonged anxieties, the wear and tear of grief, or the pressure of disappointment, we ought to ascribe the disorder of the heart's action, which at last became, by habit, a second and an unsound nature, to these moral causes? And may we not ascribe some of the phenomena of hysteria to the same chain of causes, and do you not see how vitally important it must be that we should study the moral management of such cases more carefully than we are in the habit of doing?

After having seen several cases of the disease, and having read and thought much about it, I am prepared to recommend to you the treatment which is being pursued in the case you have just seen, and which proved successful in the two last cases I have had in private practice.

The special points in this treatment are, the use of abundant quantities of wholesome, nutritious food, prolonged horizontal rest of the body, the endeavor to promote, by all possible means, a cheerful condition of the mind, and the use of iron in some shape, belladonna in small doses, and digitalis. In some cases, arsenic, as a blood-tonic, and bromide of potassium or sodium, in moderate doses, to allay general nervousness, are of great use.

And first, as to the diet. This must depend a good deal on the habits of the patients, and their own experience through life as to what may suit them specially.

The great object to be kept in view is the supply to the body of the amount of food necessary to secure its due growth and maintain its strength. If the patient takes only a half, or a fourth, or an eighth of the amount of food issued to an ordinary soldier, or sailor, or laborer, it is plain that she is taking too little, and it is the business of the doctor to insist upon more. Sometimes there is diarrhœa, at other times constipation, in these cases. Of course, the food must be regulated so as to suit either of these conditions which may exist.

Next, as to rest of the body. I believe the best thing to be done in this direction is to keep the patient as much a fixture on the bed or sofa as possible. In the two last cases I have had in private practice, I carried out this rule so rigidly in one that for seven long months the patient rarely left the bed. On a few occasions she sat up in an easy-chair for a short time; but, as each of these efforts

was followed by increased palpitation, greater frequency of the heart's action, and more severe general distress, the patient came into my way of thinking, and I had very little further trouble in enforcing the law of rest. In the other, rest, almost continuously horizontal, was kept up for several months; and both these cases recovered. Sometimes the rest cannot be enforced so persistently; and, when we cannot get the whole loaf, we must e'en be content with the half.

The mind should be kept as tranquil as possible. Hope must be infused into the patient's mind by cheering encouragement, by pleasant society, by patient and continued assurances that time and treatment will probably overcome the evil.

Iron, in some shape, should be given steadily. In one case, a pill of extract of belladonna, gr. $\frac{1}{12}$, of sulphate of quinia, gr. j, and Vallet's mass of iron, gr. ij, was given three times a day for many months. In other cases, wine of iron, or the ferrated elixir of bark, with arsenic, may be given.

Digitalis I have used in all my later cases, and always with benefit. I believe digitaline granules gr. $\frac{1}{60}$, three times a day, have sometimes answered perfectly. In the case now in this house, the violence and frequency of the heart's action have subsided more rapidly and certainly under Niemeyer's pill than with the digitaline. This pill is made of watery extract of opium, gr. $\frac{1}{8}$; powdered digitalis, gr. ss.; and quinia, gr. j: every six hours. This patient takes also the compound gentian mixture of the hospital, which contains five grains of the ammonio-citrate of iron to each tablespoonful of the mixture. The dose is a tablespoonful three times a day.

In conclusion, I will merely say that in no disease, except insanity, is there greater need of patience, perseverance, and close attention to the patient from day to day, and from month to month, than in this; but that, with these, and some general plan of treatment such as that I have just sketched, there is always good hope of an ultimate recovery.

ORIGINAL COMMUNICATIONS.

REMARKS ON SOME OF THE PHYSIOLOGICAL AND THERAPEUTICAL ACTIONS OF VERATRUM VIRIDE.

Read before the Medical Library and Journal Association of New York.

BY EUGENE PEUGNET, M.D.,

New York.

EVER since the publication of Dr. W. C. Norwood's *brochure** in 1851, the chemistry, the physiological and the therapeutical actions of veratrum viride have attracted the attention of the profession in the United States, also to some extent in France and Germany. In the May 1st issue of the *Medical Record* I published an elaborate chemico-physiological investigation of its composition and actions; but, owing to the want of time and space, I was unable to extend it as fully as I should have desired.

In these few remarks I will limit myself to the discussion of the three following points:

I. Its action as a hæmostatic.

II. Its thermic action.

III. Its mode of administration.

Its Action as a Hæmostatic.—In an elaborate series of experiments, Dr. H. C. Wood, Jr.,† was the first to make an experiment with Mr. Bullock's so-called pure viridia,‡ which demonstrated the value of veratrum viride as a hæmostatic, as follows:

"*Experiment* 17.—I exposed the pneumogastrics and femoral artery, under ether, in a powerful, very thick-necked Scotch terrier. 11.30 A. M.—Placed Bernard's cardiometer *en rapport* with the femoral artery. Arterial pressure 120 to 130 millimetres; heart-force (single beat) 5 to 10 m. Pulse 186; gave, hypodermically, gr. 1½ viridiæ sulph. 11.35.—Arterial pressure 115 to 125 m.; heart-force 5 to 10 m. 11.40.—Pulse 160; arterial pressure 110 to 120 m.; dog quiet. 11.45.—Pulse 128. 11.55.—Pulse 80; arterial pressure, when dog is quiet, 85 to 105 m., going to 120 m. when dog struggles. I now attempted to cut the pneumogastrics. In doing this on the left side, *the carotid was cut* instead of the nerve, *and there was a profuse gush of blood, which, however, ceased in a moment or two spontaneously, aided only by pressure on the outside of the neck.* The left pneumogastric was not cut. 12 noon.—Arterial pressure 60 to 70, going up to 100 m. when dog struggles. Pulse 92. 12.5 P.M.—Pulse 92; arterial pressure 85 to 88 m. 12.8.—Pulse 92; arterial pressure 80 to 85 m., going up to 100 m. when dog struggles. 12.15.—Pulse 80; arterial pressure 75 to 80 m., going up to 90 m. when dog struggles. An attempt was now made *to kill the dog by cutting the femoral artery at Poupart's ligament. The bleeding, however, ceased spontaneously in a very little while, without seriously affecting the dog. The force of the circulation had been so greatly lowered by the alkaloid, that there was spontaneous arrest of hemorrhage in both carotid and femoral artery, without dangerous loss of blood.*"

Doctors J. W. Collins§ and H. N. Eastman,‖ in two able papers issued simultaneously, published the first reports of its therapeutical application as a hæmostatic. The former states that—

1. A case of hæmoptysis, which had resisted all the usual remedies, yielded almost at once to five-drop doses of Norwood's tincture, administered every four or six hours.

2. A case of aneurism of the left subclavian, the result of an injury to the vessel in its middle third, or just behind the scalenus anticus muscle, from the small blade of a pocket-knife. The tumor was about the size of a hen's egg, and involved all the second portion, and probably the first also, of the vessel. It was accompanied with the characteristic thrill, pulsation, pain in the shoulder and arm, absence of radial pulse, coldness of limb, etc. Not deeming an operation advisable, and digital compression being impossible, the doctor administered

the veratrum, in the hope that it might *so lower the action of the heart as to favor the formation of a coagulum* in the aneurismal sac. He began with five-drop doses, increasing the dose, drop by drop, every third hour, till the full sedative effect of the medicine was produced. It was then continued, in doses of from five to twelve drops, for ten days. At the end of that time the tumor had entirely disappeared, a small hard lump only remaining, with very slight pulsation, no pain in the arm, no thrill, and considerable pulse at the wrist. The patient, a stout young negro, thinking he was well, left the doctor, but returned in two weeks with most of the symptoms as well marked as at first. The treatment was then resumed, and continued for fifteen days, the last six merely to make sure of a perfect recovery; for the tumor, with all its attendant symptoms, had disappeared, the radial pulse had become normal, and the natural temperature of the limb had returned. Twelve months afterwards he was still perfectly well.

3. In active and passive menorrhagia he has had perfect success with it.

4. In a secondary hemorrhage following amputation, equally so.

5. In two cases of carcinoma of the uterus, it arrested the hemorrhage.

6. In epistaxis, he has found it uniformly successful.

7. His friend Prof. J. T. Gilmore, of Mobile, used it with entire success, at the doctor's suggestion, in a case of secondary hemorrhage following amputation of the thigh, after other means had failed, and in which the bleeding was so persistent as to threaten life.

Dr. Eastman relates the history of two cases of hæmoptysis in which he arrested alarming hemorrhages which continued to recur notwithstanding the use of the ordinary remedies. He reduced the pulse to 45 in each case, by means of fifteen-drop doses of Tilden's fluid extract of veratrum viride, administered every three hours, till they complained of a "queer feeling" about the heart, when the pulse fell below 45; then, very properly, from the fear of causing a heart-clot, the remedy was only administered every four hours; the circulation thus kept under perfect control for four weeks, when it was allowed to return to its normal standard. There was no return of the hemorrhage in either case; and one, a clergyman, was enabled, by a change of residence, to resume his professional duties; the other, a physician, after a temporary change, resumed his practice.

Dr. Eastman advises to carry the administration of the remedy far enough to reduce the normal circulation to the lowest point compatible with the patient's safety.

Dr. J. W. Collins says "it should be given in doses of from three to fifteen drops (Norwood's tincture), repeated every one, two, or three hours, according to the urgency of the case,—always watching its effects."

Neither of them observed any unpleasant effects, such as nausea and vomiting.

I have administered the tincture for the purpose of arresting hæmoptysis, and to prevent its recurrence, in one case. The patient began with five-drop doses, which he gradually increased to ten without any appreciable effect on the circulation. I then administered it in fifteen-drop doses repeated every three hours, reducing the pulse from 101 to 60.

It is therefore evident that veratrum viride is valuable as a hæmostatic both in active and passive, also in traumatic and idiopathic, hemorrhages. That it acted in each case by modifying and regulating the heart's action and the circulation, there is no doubt. The study of its *modus operandi* is, therefore, of interest.

Dr. S. R. Percy,* in his experiments on bats and frogs, observed that the capillaries in the wings of the former and in the webs of the latter immediately became dilated under the influence of hypodermic injections of the drug, and that the movement of the blood-corpuscles through them was first retarded and finally ceased entirely.

M. Limon† noticed in his observations that the sphygmograph indicated an increased arterial tension when the pulse was reduced in frequency.

Dr. H. C. Wood, Jr.'s experiment‡ with Bullock's veratroidia and Bernard's cardiometer demonstrates that the peculiar tension observed by Limon was probably due to the increased power of the individual beats of the heart before its final paralysis by the toxic effects of the alkaloid. Dr. Wood's experiments further show that there was a marked reduction both in the force and rapidity of the movement of the blood, that the heart is not much affected at first, but that finally there is also a loss of power in the single beat. That its action on the circulation is through the sympathetic he also demonstrated by the experiments in which he divided the pneumogastrics.

Dr. C. Boldt,§ in eleven experiments on curarized frogs with veratria, the mode of action of which, although more powerful, is the same as that of veratrum viride, showed that it directly paralyzes the heart and arterial muscles, there being an immediate lowering of the pulse-frequency, in the size and force of its wave, and an increase in the lumen of the vessels.

It is well known that the circulation depends primarily on the heart's action, next, upon the contractile action of the arteries, finally, upon the slight action of the capillaries, and that the veins are passive agents.

All the above-mentioned observers have demonstrated that the arteries and capillaries are primarily affected; the heart becoming so secondarily. Dr. Wood, that the action of veratrum viride is independent of the cerebro-spinal centres. Schroff and Guldens, that veratrum acts primarily on the vaso-motor nerves.

These facts demonstrate that its action as a hæmostatic is due, primarily, to its action on the arterial system; and Dr. Wood's experiment (No. 17)

affords a beautiful illustration of the fact, the arterial pressure being at the beginning from 120 to 130 millimetres; in twenty-five minutes, 85 to 105, when the dog *struggles* rising to 120; the *carotid was then cut*, followed by a profuse flow of blood, which ceased spontaneously in a moment or two; five minutes, arterial pressure 60 to 70, rising to 100 when the dog struggles; fifteen minutes, pressure 75 to 80, rising to 90 with struggles. An attempt was then made to kill the dog by *dividing the femoral*, which was followed by the *spontaneous arrest of the hemorrhage without dangerous loss of blood.* I believe that the "profuse gush of blood" following the section of the carotid, and the loss of blood following the section of the femoral, were due to the individual action of the heart, its *vis a tergo;* for there would have been no spontaneous arrest of the hemorrhage if the contractile action of the arteries had been intact, especially as there was "*no dangerous loss of blood.*"

By comparison, we have a beautiful illustration of the action of ergot and veratrum as hæmostatics; but here the analogy ceases, for veratrum paralyzes, whilst ergot *stimulates*, causes a *contraction*, and increases *the pressure*, as shown by Dr. Alfred Meadows: he injected, subcutaneously, one grain of ergotin, in solution, into the web of a frog's foot; the circulation was observed to become much quicker, it then stopped for a few seconds, and oscillated in a spasmodic, jerking manner, and about half an hour afterwards the blood-current returned to its normal flow.

Dr. Brown-Séquard found that the vessels of the pia mater of a dog contracted during its administration, and that it acted on the spinal cord, diminishing its reflex action.*

Boldt observed in twelve experiments on curarized frogs with ergotin, that it caused a constant lowering of the rapidity of the pulse, accompanied with peristaltic or wave-like contractions and expansions of the artery; also by Nichols's and Mossop's† observations on the retina, that the ergotin diminished the capillary tint of the disk. Veratrum diminishes the blood-pressure, and equalizes the flow.

Dr. C. L. Holmes‡ has demonstrated that ergot increases the pressure in the large vessels, owing to the contraction of the minute vessels by an action on their muscular walls, and that *previous division of the vaso-motor nerves does not prevent the contraction of the minute vessels.* This diminution of calibre occurs also in the minute pulmonic vessels, causing a temporary diminution in the pressure of the systemic arteries.

We have, then, two hæmostatics; one arresting hemorrhage through its action on the vaso-motor nerves, the other by its action on the spinal nerve-centre. *The ergot arrests it immediately by pressure and contraction; the veratrum not so rapidly, but prevents a tendency to a recurrence by diminishing and equalizing the arterial pressure.*

In the treatment of aneurisms, we again have a remarkable analogy of effect between the two. Langenbeck,§ Dutoit,‖ and others have demonstrated the efficacy of hypodermic injections of ergotin in aneurisms, one of which was situated in the right supra-clavicular fossa; it acted by pressure and contraction; whilst the remarkable action of veratrum in the cases of aneurism reported by Dr. Collins was not due so much to its action on the heart as to its action on the arteries, thereby diminishing the rapidity and force of the circulation, and favoring the formation of a *laminated clot* in the aneurismal sac, as is done in the treatment of aneurisms by compression, and which occurs in those cured spontaneously.

Its Thermic Influence.—Bärensprung, Traube, Wunderlich, Seguin, and others,¶ have demonstrated the value of the thermometer as a means of diagnosis and prognosis, also as an indicator of therapeutical applications. Although many have written on veratrum viride and its actions, only Oulmont,** Limon, E. Amory, and S. G. Webber†† have alluded to its thermic action. It was also strikingly shown in the experiments that I made with one of its alkaloids, the veratroidia, and with its two alkaloids when combined, the temperature being invariably reduced from two to five degrees, whether in physiological experiments or in its therapeutical application. These facts would most certainly lead us to conclude that its great power in inflammatory and febrile affections is in a high degree due to this action; and would it not be well for us to study its action more closely in those affections in which the temperature rises to 108.°30 Fahr., the prolongation of which would indicate a fatal termination?

Its *modus operandi* in these cases as a depressant of caloric can only be explained by its primary action on the vaso-motor nerves through the circulation. For if this action of veratrum viride and of its alkaloids was due to their action as spinal motor depressants, as has been asserted by some observers, it would disprove the observations of Schiff and others, that the increase of caloric was due either to paralysis of the spinal nerve-centre, or to an action independent of the section of the sympathetic nerve. Nor can it be explained exclusively by the supposed accumulation of carbonic acid in the blood, and its subsequent action on the cerebro-spinal centres; for in all the recorded cases of poisoning there is not a single one noted in which the patient died from asphyxia or coma; nor did they even present the appearance of either. It is, however, true that in various experiments the animals *apparently* died from asphyxia; but all the observers agree as to the heart's action being arrested at the diastole, which rather confirms Maurice Schiff's‡‡ and C. Boldt's views; especially as the heart failed to respond to electricity,

whilst the voluntary muscular fibres retained their contractility.

I conclude. therefore, that—

I. Its action as a hæmostatic; and

II. Its action as a depressant of caloric, are due entirely to its action upon the vaso-motor nerves.

(To be continued.)

A CASE OF LARGE SMOOTH WHITE KIDNEY (CHRONIC CATARRHAL NEPHRITIS.)

Reported, with specimens, to the Pathological Society of Philadelphia, December 12, 1872,

BY JAMES TYSON, M.D.,

One of the Attending Physicians to the Philadelphia Hospital, etc.

C. R. C., a native of Pennsylvania, aged 28 years, a painter by occupation, was admitted to the Philadelphia Hospital Sept. 4, 1872. He was in good health until three years ago, when he became affected with what appeared to be epileptic convulsions. He had, at this time, repeated convulsions, which recurred at the end of six months, and again six months later. Since then they have been increasing in frequency, until at present there is not more than ten weeks' interval. He had the last fit five weeks before admission.

He has been frequently exposed to wet and cold weather, and during the Chicago fire such exposure continued for several days, a few days after which he entered a hospital in that city, with diarrhœa. In November, 1871, swelling of the feet appeared, and about the same time he noticed puffiness of the eyelids in the morning on rising. Gradually this œdema extended, until the whole body became involved. The condition of his kidneys was recognized in the Chicago Hospital, and he was treated with "broom tea" and hot-air baths.

On admission, his condition was as follows: His face was swollen, sallow and sodden in its appearance, his extremities were œdematous, and there was some ascites, but no hydrothorax. He was freely passing urine which was highly albuminous and contained granular and hyaline casts. He was ordered f℥ij of solution of the acetate of ammonia three times a day, with solution of the acetate of iron as often.

On Nov. 30 is found the following note: "He is passing 65 ounces of urine in twenty-four hours, and the swelling appears to be steadily diminishing, but it is still quite decided in the face. There is still abdominal effusion, while his legs and arms pit somewhat on pressure."

Nov. 12.—This morning the right side of his face was very much swollen, though he is still passing 65 ounces of urine in the twenty-four hours. Infusion of scoparius, f℥ij three times daily, was ordered internally, and cloths wet with infusion of digitalis were directed to be applied to the abdomen. The solution of acetate of ammonia was omitted.

Nov. 13.—He has had three convulsions in the past twenty-four hours, during which he has passed but 34 ounces of urine. His face is enormously swollen, and he can scarcely open his eyes. He was ordered, in addition to the above treatment, ⅛ gr. of elaterium.

Nov. 14.—Elaterium has operated freely. Condition little altered, but has had no more convulsions.

Nov. 23.—His face seems less swollen, but the ascites is marked. The urine is almost solid with albumen, and contains highly granular casts and compound granule-cells. He was ordered in addition to the above a grain of digitalis and a grain of squills three times a day. The infusion of digitalis to the abdomen, which was discontinued several days ago, was again ordered, and the broom tea was continued. He is growing weaker.

An ophthalmoscopic examination of the eyes by Dr. William F. Norris gave the following results: *Right* eye. The veins and arteries of the disk have nearly their normal size; the fibres of the retina, spreading out from the disk, whitish and œdematous, can be followed nearly the disk's diameter into the retina; this condition is more marked along the course of the large veins. The choroid between the disk and macula lutea appears woolly and granular. There are no blood extravasations, no white patches. The macula is plainly visible, the fovea centralis showing yellow, reddish-brown pigmentation around it. *Left* eye nearly in the same state.

Nov. 27.—Bowels are quite loose, and swelling in abdomen is evidently diminishing. Urine 44 ounces.

Nov. 30.—Has had numerous watery stools since last note, with which urine was also passed, so that its quantity could not be accurately estimated. Œdema and ascites are diminishing. A little opiate was ordered to control the bowels. All other treatment, except by stimulants, omitted.

Dec. 2.—Œdema is almost absent from the extremities; the face is still swollen, but the abdominal effusion is greatly diminished. Evacuations are still watery, but not so numerous or large. Passes urine with stool, so that quantity is unknown. Is rapidly growing more feeble.

In 640 cc. of urine, sp. gr. 1009, passed from 2 P.M. November 30 to 2 P.M. December 1, a volumetric analysis determined 3.424 grammes, or about 52.8 grains, of urea. He died suddenly on December 3, 1872, neither in coma nor convulsions.

Post-mortem examination, eighteen hours after death. Œdema has almost entirely disappeared. No effusion in *pleural cavities*; slight old adhesion in lower part of left lung. The *pericardium* contained f℥iijss of fluid. There was found in the *left ventricle* a white, firm, fibrinous clot which extended into the aorta five inches, furnishing a perfect mould of the arch, from which passed off also as perfect moulds of the innominate artery and its two divisions, and of the left carotid and subclavian with their chief branches. In the *right ventricle* was also found a clot extending into the pulmonary arteries and branches. The *spleen* was elongated and lobulated, and contained an infarctus, but was otherwise normal in structure. The *kidneys* were perfect examples of the large smooth white variety, the left weighing 11½ ounces, the right 11 ounces. The capsule was readily removed, and on section the convoluted portion was greatly enlarged, and contrasted strongly in its dead-white color with the normal red of the cones. An attempt to minutely inject one of these kidneys was unsuccessful. *Microscopical* examination showed the tubules and the intervals between them to be filled with granular matter.

Remarks.—This case presented the usual course of a so-called chronic catarrhal nephritis. The point of evident interest is the connection between the convulsions and the disease of the kidneys. Were they the result of uræmia? Much might be written upon the subject without even then definitely settling the question. The convulsions first made their appearance three years prior to his death. Renal disease was recognized one year before he died. This affection was, however, of a kind, as confirmed by post-mortem examination (catarrhal nephritis), which is not insidious in its irruption, but manifests its characteristic symptoms more or less suddenly; and though commonly attended by convulsions in its latter stages, these are seldom the first discovered symptom. Had the case proved to be one of *chronically-contracted kidney*, which often

exists for years without manifesting itself by any symptom, and as often without previous warning explodes in a convulsion, a relation between the early convulsions and the disease might be admitted. As it is, we are inclined to admit none; but to consider the patient an epileptic, who contracted, by exposure, acute nephritis, which passed over into the large white kidney (chronic tubal nephritis of Dickinson), of which he died in something more than a year after the renal affection set in.

That the convulsions were, however, at a later stage influenced by the disease and rendered more frequent by uræmia, we think is beyond question; and that the convulsions which he had while under treatment at the hospital were at least due to the action of the peculiar poison of uræmia upon a brain epileptically susceptible, if this poison was not the sole cause, is proved likely by the results of volumetric analysis, which showed a marked diminution in the normal proportion of urea in the urine.

The immediate cause of his death, as shown by the post-mortem examination, was evidently heart-clot.

Appended is a table of the quantity of urine passed per twenty-four hours, during a portion of his residence in the hospital:

NOTICE OF AN ARTICLE BY GIRAUD-TEULON ON THE TRANSIT OF VENUS OVER THE SUN.

BY GEORGE C. HARLAN, M.D.

AT a time when every one who reads the newspapers feels some interest in the transit of Venus over the sun, announced by astronomers for 1874, a short notice of an article on the subject, from an ophthalmic point of view, by Giraud-Teulon, may not be out of place. It appeared in a recent number of the *Annales d'Oculistique*, in the form of a criticism of a lecture by M. Wolf, of the Paris Observatory.

Astronomers look forward to this transit of Venus as an event of great interest and importance, as affording an opportunity to determine more exactly the distance of the earth from the sun; and several of the European governments are already occupied with preparations for observing it correctly.

Of course, the accuracy of the calculations based upon the observations will depend in a great measure upon the exactness with which the precise moment of contact of the two disks is noted; and this is the point in which oculists are interested.

In this and similar observations, a serious difficulty has been met with in the observation of the point of contact of the edges of the two disks by a dark spot which has been described, for more than a century, under the name of the "*goutte noire*," or "*ligament noir*," and which seems to have been something of a "*bête noire*" to the astronomers.

It has been held that this was a natural and necessary phenomenon, and that the real moment of contact was marked by the formation of this dark line as the disks came together, and its disappearance as they parted. An explanation was sought in the "irradiation of light," an expression which was rather loosely and vaguely used.

M. Wolf illustrated the principle of this explanation by reference to the appearance of the new moon. When its crescent is little more than a curved line, the rest of its surface is not quite invisible, but is dimly discerned by light reflected from the earth, and the contour of the bright crescent seems to belong to a larger circle than that which bounds the obscure portions. Thus it has been said that any object brightly illuminated appears larger than it really is.

On this supposed fact the explanation of the black line was founded, and its appearance, in all observations of this kind, was considered an absolute necessity.

Some excellent observers, however, supplied with the best instruments, were unable to see it,—a fact sufficient almost of itself to destroy the generality of the phenomenon and reduce it to an accident of observation.

M. Wolf proved this to be the case by a series of experiments, in which the conditions of the astronomical observation were produced artificially.

These experiments showed that the dark line, instead of marking the beginning and end of the transit, considerably preceded the former and followed the latter, and the experimenter concluded that the "ligament noir" was not an essential, but a foreign, phenomenon, whose appearance obscured the real phenomenon and led the observer into error.

This conclusion Giraud-Teulon pronounces unassailable. He differs widely, however, from M. Wolf in his theory of the cause of the obscuration, for which the latter searches in spherical aberration of the telescopic image. Of the figures exhibited in proof of this view, Giraud-Teulon says that he cannot avoid a suspicion that the ocular apparatus of the observer has played the

principal *rôle* in their production. He further claims that, in experiments similar to those of M. Wolf, he has been able to avoid the appearance of the "ligament noir," or to produce it at will, by preserving a perfect adaptation between the refraction of the instrument and that of his own eye, or by disturbing that relation. He recommends the interposition of a stenopœic apparatus between the eye of the observer and the eye-piece of the instrument, and believes that this would dispel the obscuration and bring out clearly the point of contact of the images.

According to Giraud-Teulon, the phenomenon of the "ligament noir" has the same origin as that of the apparent increase of diameter of the lunar crescent and the apparent multiplicity of its horns, and, like it, will disappear on accurate adaptation of the eye.

This illusion in the appearance of the lunar crescent, the rays of stars, and similar phenomena, are known to be caused by monocular polyopia, the result of what Donders calls normal irregular astigmatism, which is dependent on the structure of the crystalline lens.

The principle of this explanation may be illustrated by reference to the optometer of Scheiner, of which Dr. Thomson has made a familiar and valuable means of diagnosis. If a distant point of light be viewed through several small holes close together in an opaque screen,—pin-holes in a card, for instance,—as many lights will be seen as there are holes, if the eye is not accurately focussed ; but if the refraction of the eye is perfect the images will all fall upon the same point of the retina, and, covering each other accurately, will be seen as one.

In much the same way, all of the sectors into which the crystalline lens is divided form separate images, which will fall upon the same spot of the retina if the adaptation of the eye is perfect ; otherwise they will be seen separately, if the object is small enough, or will cause obscuration and confusion by partial covering and overlapping, if it is larger. The former can be proved by approaching a small black speck on a white ground gradually to the eye, until it is brought within the distance of distinct vision, when it will appear as a circle of gray spots. The latter has been illustrated by reference to the illusion in the appearance of the moon.

I have already occupied too much space, and will not follow further the argument of the author or presume to trespass with any opinions of my own upon even this border region of the great science of astronomy ; but that "the object of an optical instrument is to present, at a certain distance from the eye, a certain definite image," and that therefore "the first practical problem to be solved should be to regulate the relations that must exist between this image and the eye of the observer," is a proposition that no one who has had much experience in the use of the ophthalmoscope, particularly by the direct examination, will be slow to accept.

"Know thine own eye" might be a not inappropriate injunction to all engaged in optical experiments or observation.

The author regrets the neglect, on the part of physicists, of the physiology of vision, and says there is good reason to believe that men of the greatest learning too often attribute to the outer or objective world phenomena that exist only in the imperfections of their own eyes.

Myopic individuals may find consolation in the fact that, though emmetropia may be the rule in "the eye of the peasant, the hunter, or the sailor, it is much less invariably so in that of the educated classes, and becomes less and less common as we ascend in the scale of the classes perfected by close work," so that "the more learned one is, the less sure can one be of a perfect eye."

Ruptured Jejunum—Absence at First of Serious Symptoms (*Lancet*, December 14, 1872).—John R., aged 32, brewer's man, was admitted into the London Hospital, under the care of Mr. Rivington, February 19, 1872. Patient was walking across a plank laid over a brewer's vat, when he missed his footing, and fell a distance of sixteen feet. When he came to the hospital, he was examined by the house-surgeon, who was unable to detect any sign of a serious injury, and, consequently, gave him an out-patient's ticket. Later in the day he returned, complaining of pain in the chest and also at the lower part of the belly. He was admitted as a case of contused chest. The patient was a very stout man, with much fat on his body, and it was therefore difficult to examine satisfactorily his ribs and sternum. His water was drawn off, and it was like dark tea, without blood. He vomited once when he came in. Subsequently he had a disposition to vomit, but did not bring up anything. When seen about five o'clock by Mr. Rivington he did not exhibit the usual signs of the injury from which he was suffering ; he did not complain of pain in the abdomen, he was not sick, and he was not in a state of collapse. In the course of the evening severer symptoms came on, and he died on the following morning at 11 A.M. At the post-mortem examination the jejunum was found ruptured near the duodenum, and the sternum was fractured.

Nitrite of Amyl in Melancholia (Höstermann : *Wiener Med. Presse*, October 20, 1872).—In accordance with the suggestions from English sources and Prof. Meynert, of Vienna, Dr. Höstermann has made a series of experiments with this drug in cases of melancholy.

Inhalations are preferable to subcutaneous injections or to the internal administration of the remedy.

In 10 to 15 seconds the pulse becomes more frequent ; in 30 to 40 seconds the face becomes red, the conjunctiva injected, and the subjective warmth of the body increases. At the same time the arteries pulsate more vigorously, the head feels constricted, and the patient experiences the feelings of mild intoxication after wine-drinking. With these symptoms the patient is more lively, and shows it both in his features and his manner. The external signs of the drug disappear in three-quarters of a minute after the cessation of the inhalations ; but there seems to be a somewhat more permanent change for the better in the psychical condition of the patient.

This treatment is not suited to those cases where the melancholia depends upon some cause of exciting anxiety, for the excitement produced by the inhalation of the remedy will only increase the malady. It is rather suited to those cases of melancholia due to sluggish circulation and impeded nutrition in the brain.

PHILADELPHIA
MEDICAL TIMES.
A WEEKLY JOURNAL OF
MEDICAL AND SURGICAL SCIENCE.

The Philadelphia Medical Times is an independent journal, devoted to no ends or interests whatever but those common to all who cultivate the science of medicine. Its columns are open to all those who wish to express their views on any subject coming within its legitimate sphere.

We invite contributions, reports of cases, notes and queries, medical news, and whatever may tend to increase the value of our pages.

All communications must bear the name of the sender (whether the name is to be published or not), and should be addressed to Editor Philadelphia Medical Times, care of the Publishers.

PUBLISHED EVERY SATURDAY BY
J. B. LIPPINCOTT & CO.,
715 and 717 Market St., Philadelphia, and 25 Bond St., New York.

SATURDAY, JANUARY 18, 1873.

EDITORIAL.

FREE SUMMER PARKS.

WITH the opening of the new year it seems appropriate to bring forward again—and indeed it is none too early—the subject of plans for preventing the infantile mortality of the summer. Many of our readers will remember a communication from Dr. Henry Hartshorne, which appeared in our columns in September last, proposing the establishment of free parks or camping-grounds, where the poor could go by families, and escape the baleful effects of city air. Another article on this subject, by Dr. J. M. Toner, of Washington, published in the *Northwestern Medical and Surgical Journal* for November, is before us, with editorial comments by Dr. H. C. Hand.

We believe that to the *New York Times* is due the credit of proposing the free excursions for the poor children of that city, which were so successfully organized, and which were as successfully imitated by the benevolent here and elsewhere, during the heated term of 1872. The plan now under consideration is an expansion of that excellent scheme. We have at present neither space to discuss it, nor indeed any definite ideas to bring forward as to how or where it can be practically carried out. All that we can do is to invite those who may be able to devise arrangements for the purpose, or who have any suggestions to offer in regard to the matter, to take the earliest opportunity of so doing, and to place our columns at their disposal.

Funds for so admirable an object would, we feel assured, flow freely into the treasury of a properly organized association. But in order that the greatest amount of good may be accomplished, an early and energetic start should be made in the work.

"HOSPITAL SUNDAY."

OUR readers will doubtless have seen this caption in many of the issues of the medical periodicals in Great Britain. It hardly needs either explanation or comment. Assuredly no outgrowth of Christianity can be more genuine or legitimate than the devoting of collections taken at places of worship, and as a part of that worship, to the relief of human suffering. In this city it has for many years past been the custom of the Protestant Episcopal churches to place the money taken at the service on Thanksgiving Day to the credit of the hospital of that denomination; and, for all we know, other sects may have done the same by their own kindred institutions.

We should like to have this a recognized feature of the vast network of charities which exists in so many American cities. Whether by agreement or by the action of individual sects, it would go far towards strengthening the hold of the various beneficent institutions upon the affections and sympathies of the public. Services are held by nearly or quite all the denominations on the day known in this country as Thanksgiving Day, which would therefore be perhaps more suitable and convenient than any given Sunday as the fixed time for remembering the claims of the sick and suffering upon the benevolence of their more favored brethren. Experience has shown that far more is accomplished by such united action than by the irregular movements of individuals, when funds are needed to meet the steadily recurring demands of charitable objects or institutions.

THE MORTUARY LIST FOR 1872.

DURING the year just ended, the profession in this city has suffered serious losses by death. Some of those who have "gone over to the majority," as Jackson, Dickson, Gerhard, Mason, Bell, Wistar, Brookfield, and LaRoche, were men far advanced in life, whose day of active usefulness had long waned. But the destroyer claimed also some, as Hollingsworth, Fish, Robinett, Pepper, and L. S. Stillé, who had not reached the usual limit of man's years of prime. For the unblemished records and honorable memories left by these our brethren, we may well be thankful.

CORRESPONDENCE.

To the Editor of the Philadelphia Medical Times:

DEAR SIR,—The writer is the unfortunate author of a paper published in the last volume of the Transactions of the American Medical Association,—a paper which has suffered most grievously from careless proof-reading.

Permit me to point out some of the errors, and their character will sufficiently indicate that the epithet careless is not at all too strong.

On page 126 of the volume referred to, I find "accommodations" substituted for accumulations, and "insidious" for invidious,—in each instance the substitute destroying the meaning of the sentence in which it occurs, if not making utter nonsense. On page 127 the words "round-shirts," "persistence," and "decorations" are given for roundabouts, penitence, and declamations.

On the next page the reader finds in part of a sentence the following, "Carlyle, Mill, Huxley, and Rankin," and possibly wonders who Rankin is. Ask the intelligent and careful proof-reader. The author wrote Ruskin.

On page 130 a sentence reads as follows: "And possibly, too, the best ideal of a medical journal has not yet been obtained, has not yet been developed with the actual." Replace "obtained" by attained, and "with" by in, and the sentence is tolerable; but, as printer and proof-reader have made it, it is intolerably bad.

Other errors almost as mortifying as those that have been mentioned can be found; but the list is long enough. A man, no matter how poor he is, does not like to see his children, no matter how homely they are, walking the streets in rags. Almost equally as trying is it for one to have the children of his brain thrust ragged and disorderly before the public, when the rags and disorder are not of his producing.

Now, the moral of the story is, in my opinion, this: Authors have the right, and should always have the opportunity, of correcting their proof.

T. P.

ANNUAL REPORT OF THE HOSPITAL OF THE PROTESTANT EPISCOPAL CHURCH.

THE Twenty-first Annual Meeting of the Contributors to the Hospital of the Protestant Episcopal Church was held January 7, 1873, pursuant to the charter, at the office, 708 Walnut Street. George Washington Smith, Esq., was called to the chair, and the Rev. John A. Childs, D.D., was appointed Secretary.

The Report of the Board of Managers, together with the annual statements and accounts, was then presented, and on motion it was

Resolved, That the Report and accompanying documents be referred to the Board of Managers, for publication at their discretion.

The following is an abstract of the Report: During the year 940 patients have been admitted; at the date of last report, 104 patients were in the hospitals at the first of the year, making the whole number treated during the year, 1044.

Of these, 941 were discharged, of whom 643 were cured, 167 improved, 57 unimproved, and 74 died, leaving 103, or 67 men, 30 women, and 6 children, in the wards at the end of the year.

There have been 6147 Dispensary patients prescribed for during the year. Of this number, 4448 were medical and 1699 were surgical cases.

The average daily number of patients in the wards of the hospital was $10\frac{3}{4}$.

The average duration of treatment was 38 days.

The average daily number attending the Dispensary, 20.

The average number of prescriptions daily was 33.

No. of prescriptions given in Dispensary for the year ending December, 1872, 10,170.

Cost of maintaining each patient, $\$39\frac{80}{100}$.

Daily cost of maintaining the hospital, including medicines for Dispensary patients, $\$113\frac{88}{100}$.

Total cost of maintaining the hospital for the year, $44,035.71.

For the support of the hospital, the Treasurer reports the following amounts, viz.:

From individuals and churches for the support of beds	$4,457.86
" individual contributions	2,331.00
" churches on Thanksgiving Day	12,722.36
" interest from moneys invested	12,863.25
" Grasby Fund for the support of patients suffering with diseases of the chest	3,324.09
" George Washington Smith for the endowment of a bed for Christ Church (permanent)	5,000.00
" Estate of Edward H. Trotter ($5000, less inheritance tax)	4,762.50
" Superintendent for board of patients	8,275.04
	$53,736.10

At the meeting, I. V. Williamson, Esq., presented to the hospital, through Mr. John Welsh, $35,000,—this, with previous donations of $15,000, making a total of $50,000, the interest of which is to be used for the support of the hospital forever.

S. R. Knight, M.D., *Superintendent.*

REVIEWS AND BOOK NOTICES.

A Manual of Histology. By Prof. S. Stricker, of Vienna, Austria, in co-operation with Th. Meynert, T. von Recklinghausen, Max Schultze, W. Waldeyer, and others. Translated by Henry Power, of London; James J. Putnam and J. Orne Green, of Boston; Henry C. Eno, T. E. Satterthwaite, Edward C. Seguin, Lucius D. Bulkley, Edw. L. Keyes, and F. E. Delafield, of New York. American Translation edited by Albert H. Buck, Assistant Aural Surgeon to the New York Eye and Ear Infirmary. With 431 Illustrations. Large 8vo, pp. 1106. New York, Wm. Wood & Co., 27 Great Jones Street, 1872.

The profession are already so familiar with "Stricker's Histology" that it is scarcely necessary to explain either the object or the scope of the treatise. The present edition, by Wm. Wood & Co., furnishes the entire treatise in a single large and conveniently-arranged volume. It includes as much of the translation of Mr. Power as is contained in the first volume of the New Sydenham Society's Translations, of which two volumes

only have appeared. The translation of Mr. Power covers 406 pages of the present edition; but the remaining articles are translated by the American gentlemen above named. Nearly two-thirds, therefore, of the book are translated by Americans, who are physicians especially interested in the departments which they have undertaken. In this there is evident advantage, as one who is already familiar with a subject is the more likely to grasp obscure points, which are perhaps rendered still more obscure by being couched in a foreign idiom. There is also likely to be more freshness about an article thus translated than if it form, in the original, one of a large number, and by different authors, translated by a single individual; for the weariness which must necessarily grow upon the translator of so large a volume is not relieved by the increasing familiarity which he must acquire if the papers are all by the same author.

This series of papers, edited and in many instances written by Prof. Stricker, constitutes at once the most extended and most accurate treatise on histology extant. And as the study of histology is a subject which admits only the latest and most accurate information to its aid, this work must necessarily supersede all others. It becomes, therefore, absolutely indispensable to every histologist and physiologist in the world, as well as to all physicians and surgeons who would pursue their departments with all the light of modern science. This beautiful edition of Wood & Co., which reflects great credit at once upon the translators and the publishers, will be bought by most who are not subscribers to the New Sydenham Society's valuable publications, while its convenience of form and anticipation of a large portion of Mr. Power's translation will cause it to be purchased by many who are also subscribers to the Society's translations.

English and American physicians have been signally fortunate in the opportunities afforded in the last few years to avail themselves of the labors of German investigators, and in Stricker's Histology, Rindfleisch's Pathological Histology, Niemeyer's practical works, and Frey on the Microscope, they possess a storehouse of information which must not only increase their intelligence, but also their usefulness. J. T.

The Anatomy and Development of Rodent Ulcer. A Boylston Medical Prize Essay for 1872. By J. Collins Warren, M.D. 8vo, pp. 65. With Two Colored Plates. Boston, Little, Brown & Co., 1872.

This essay is one of the results of a growing inclination on the part of young American physicians and surgeons to make original researches in special subjects, —a work for which many of them have been prepared by instruction and experience in the laboratories of Germany and Austria. Dr. Warren is a young surgeon of Boston, who has evidently profited by his opportunities. He has not only carefully studied cases, but has also made thin sections of the morbid tissue, and furnished accurate drawings of the microscopic appearances afforded by them. It is but justice to state, however, that these drawings, as Dr. Warren informs us, were made upon stone by Dr. H. P. Quincy, artist to the Massachusetts General Hospital, from originals furnished by the author. Dr. Quincy is perhaps the only gentleman in this country who has made the subject of drawing the magnified pictures afforded by the microscope a subject of special study. The importance and success of such drawing have been amply shown in the results of the labors of Mr. T. West, of London.

The observations of Dr. Warren lead him to believe, with Thiersch and Billroth, that rodent ulcer is a form of epithelial cancer, but "the mildest form of cancer with which we have to deal." The following are his conclusions:

1. All those cases of rodent ulcer examined are forms of epithelial cancer.

2. They differ from those forms of epithelial cancer of which cancer of the lower lip is the type, in the small size of the epithelial cells.

3. These ulcers may be divided histologically into two different groups, according to the arrangement of the cancer-cells,—viz., into tubular or alveolar.

In the course of some remarks on the development of the disease, is furnished an admirable *résumé* of the *origin of the cancer-cell*, which should be familiar to every surgeon as well as pathologist. In conclusion, we are informed that "in summing up, then, the results of these observations, we find that in certain cases—

"1. The formation of the cancer-cells is preceded by an escape of the white blood-corpuscles through the walls of the vessels, and an accumulation of similar cells in the adjoining lymphatic canals.

"2. That this is followed by an apparent transformation of these cells into cells resembling strongly the epithelium of the rete Malpighii.

"3. That the epithelium of the parts affected does not appear to take an active part in the process, but may exert a certain influence on the character of the formation taking place.

"4. That the cancer-cells may lie in the lymphatic spaces of the connective tissue, and do not invade, to any appreciable extent, the lymphatic vessels."

The Journal of Anatomy and Physiology. Conducted by G. M. Humphry, M.D., F.R.S., etc., and Wm. Turner, M.B. Second Series. No. XI., Nov. 1872. Macmillan & Co.

This excellent number of one of the best periodicals published is full of interest to the physician and surgeon. We have only space to note the titles of some of the leading papers: a notice of quadruple mammæ in two adult brothers; tissue-metabolism, a continuation; observations on the distribution of some of the nerves of the head and neck; sphygmography; the effect of exercise on bodily temperature; observations on the structure of the human placenta; action of digitalis on the blood-vessels; on the Kombé arrow-poison; peculiar malformation of the leg and foot; effect of stimuli on the secretion of the parotid gland; valves in the renal veins; experiments as to the causes of the presence of bile-pigment in the urine.

The reports on the Progress of Anatomy, on Physiology, and on the Physiological Action of Medicinal and Poisonous Substances, are complete and full of valuable material.

GLEANINGS FROM OUR EXCHANGES.

Mode of Growth of Long Bones (*British Medical Journal*, Sept. 28, 1872).—At the recent meeting of the French Association for the Advancement of Science, at Bordeaux, M. Ollier (Lyons) stated the results of his recent experiments on the mode of growth of the long bones. The theory of peripheric growth, which he has held for a long time, has been lately combated by the learned German doctors Wolf, Calmann, and Meyer, who are supporters of interstitial growth. M. Ollier has observed anew a great many times that two nails placed on the diaphysis of a bone, at an accurately measured distance, are separated by the same space when the animal, having become an adult, is sacrificed. In very young animals there is sometimes a slight divergence, never exceeding more than a fourth of the whole length of the bone. This fact would seem

to weaken the theory, if one did not know that very young and in consequence soft bones are under the general law of growth of soft tissues, of which the development is interstitial. A more considerable divergence of the osteoplasts in adult bones has also been made an objection to the theory of peripheric growth; but the researches of Ranvier have demonstrated the variableness of these elements, and in consequence their utter uselessness in this question. When the cartilage of conjugation is removed, the growth of the bone is stopped, or at least diminished. Interstitial growth is observed occasionally in certain birds, and in some mammals; but in this last case the anomaly explains itself, because the bone, softened by inflammation, has taken the properties of the soft tissues. Moreover, this growth is never more than a very small fraction of the length of the bone which is the seat of it. Passing from the normal to the pathological growth of bone, M. Ollier remarked that since 1867 he has shown that irritation of the diaphyses of a long bone provokes the lengthening of this bone; whilst the irritation of the cartilage of conjugation leads to the arrest of its development, and that not by the more rapid solidification of the epiphysis, but by a simple perturbation in the work of ossification. The clinic confirms the results of the experiment. Another fact, which has great practical importance, is the inequality of the part of the two cartilages of conjugation in the development of bone. The humerus grows especially by the superior cartilage of conjugation; the radius and the ulna, on the contrary, by their inferior cartilage, in such a way that the constituent parts of the elbow are only of very slight utility in the general development of the superior limb. The reverse takes place in the articulation of the knee and the bones which form it. M. Ollier insists on the importance of these facts, because of the results that attend articular resections practised on children. He has observed since 1861 that, after resections of the elbow in young children, the superior limb continues to grow, whilst the inferior limb hardly grows any more after resection of the knee. The deformity which results from this stoppage of the development is more and more exaggerated as the fellow-limb continues its normal growth. After resections, as after certain inflammatory lesions, a growth lengthwise of the limb operated on is sometimes observed. This lengthening is not accompanied by hypertrophy of the bone; it becomes, on the contrary, lighter. Hence M. Ollier has called this growth the atrophic lengthening. M. Ollier explains this anomaly by the diminution of the pressure which the bones exercise on one another. The diminution of this pressure leads, in fact, to an atrophic lengthening. This it is easy to observe in the bones of a paralyzed limb, but without waiting for that general atrophy which soon succeeds the functional inertia of the limb.

Detection of Blood-Stains. — Dr. Edward S. Wood, in the *Boston Medical and Surgical Journal* for January 2, reports that *Fres. Zeitsch. f. Anal. Chem.* (1872, ii. p. 244) contains a note from Dr. Helwig, contradicting a statement made in the *Chem. Centralb.*, 1871, p. 37, that a solution of blood-pigment in iodide of potassium cannot be used for the production of blood-crystals, but only for spectroscopic examinations. It has long been known that a solution of iodide of potassium will extract from clothing the slightest trace of blood-coloring matter, it being possible to obtain a solution suitable for testing even when the clothing has been washed and the stain is very old. In the present instance Dr. Helwig exhibited a specimen of hæmin-crystals which he had obtained by treating a piece of linen upon which a blood-stain had existed for sixteen years, with a solution of iodide of potassium. The residue left after the evaporation of one drop upon a glass slide gave beautiful hæmin-crystals upon the application of Teichmann's test, when the remainder of the solution, examined by the spectroscope, gave an absolutely negative result.

Teichmann's test, the ordinary test for hæmin-crystals, is performed by rubbing upon the dried residue in a watch-glass or on a microscope-slide a very small quantity of ammonic chloride or common salt, adding to the mixture a drop of glacial acetic acid, and warming until bubbles form under the covering glass, showing that the boiling-point of the acetic acid has been reached. Upon cooling, crystals of hæmin can be detected by the microscope.

In the same journal (1872, i. p. 29) we find mentioned by H. Struve an additional test for blood-pigment, which is applicable to the testing of both urine and clothing-stains for blood. This test is based upon the precipitation of hæmatin from an acetic acid solution by tannic acid as tannate of hæmatin, and may be performed in the following way. To the urine or any other liquid suspected to contain hæmatin is added a little ammonia-water or potassic hydrate, then a solution of tannic acid, and finally acetic acid, to distinctly acid reaction. If hæmatin be present, a reddish-brown precipitate, tannate of hæmatin, is formed, which quickly settles and can be very easily washed and collected on a filter. This precipitate, after drying, gives a residue with which we can obtain hæmin-crystals by performing Teichmann's test. This test is far superior to Heller's test for blood in the urine, in which the hæmatin is mechanically carried down with the earthy phosphates, after the addition of ammonic or potassic hydrate. By the above method the author claims to have detected the presence of blood when all other reactions have failed; for instance, in urine when he could not detect the albumen by any of the ordinary tests. In 20 cc. of urine to which 0.023 per cent. of blood was added, a precipitate was obtained which permitted numerous examinations for hæmin-crystals to be made by Teichmann's test.

The same author (*Fres. Zeitsch.*, 1872, ii. p. 150) states that he has separated from the blood two new coloring-matters. One is soluble in alcohol and water, difficultly soluble in ether, and forms, when dry, a dark greenish-brown mass which chars without puffing up, and, after ignition, leaves a residue, consisting of oxide of iron, phosphoric acid, and silica. It is precipitated from its solution in water by acids, and the application of Teichmann's test does not yield hæmin-crystals. The other pigment separates in the form of dark bluish-black microscopic crystals, reminding one of indigo. These crystals are insoluble in water, alcohol, ether, chloroform, and acids, but are soluble in alkalies with the production of a dark-brown solution. If precipitated from the alkaline solution by acetic acid, and the precipitate subjected to Teichmann's test, the result is the most beautiful hæmin-crystals. Concentrated sulphuric and nitric acids dissolve this pigment with a greenish-yellow color, concentrated hydrochloric acid and aqua regia decompose it, and glacial acetic acid is without action upon it, unless ammonic chloride has been previously added, in which case it dissolves it, forming a dark-brown solution, which, upon evaporation, yields large pure hæmin-crystals. After ignition, the residue consists of pure oxide of iron. These crystals he considers to be identical with Virchow's hæmatoidin. An elementary analysis of these pigments is promised.

The Cure of Stammering (*N. Y. Medical Record*, Jan. 1).—The mode of treatment followed by M. Chervin, of Lyons, in this affection, has lately been the subject of investigation by a commission appointed by the Department Council. The commissioners state

that they find the system successful, rapid, and permanent in its effects; which opinion confirms those of earlier date, given by commissions appointed in France, Belgium, Spain, etc.

Eight patients, severely affected with stuttering, were submitted, under the observation of the commissioners, to the system of M. Chervin. They varied in age from ten to twenty-nine years, and none of them could speak without stammering to an extent most distressing to themselves and to those who heard and saw them. In some cases the act of speaking was accompanied with convulsive movements of the mouth and eyes; in others, with spasmodic respiratory movements. Some had stammered from their infancy; in others the defect had been caused by a shock to the nervous system. Ten days after they had been placed under M. Chervin's treatment they were seen by the commissioners, and each of them could then speak distinctly, without stammering or hesitation; and on the 28th they were pronounced cured, speaking then with natural ease and rapidity.

The system is as follows. All mechanical contrivances are discarded; but he teaches the patient, by means of a large number of exercises, gradually to pronounce, with distinctness, vowels, consonants, syllables, and sentences. He pays great attention to the act of respiration, which he seeks to regulate. He teaches his patients to take at certain intervals a slow but normal inspiration, which is succeeded by an even, continuous, and loud expiration, during which pronunciation is effected. The course of treatment occupies twenty days, the time being divided into three periods. During the first the patient is restricted to complete silence, so that the old habit may be broken; during the second period the patient is taught to speak slowly and deliberately; and during the third period he acquires the practice of speaking fluently and without clipping the words. This method is stated to have succeeded in the most difficult cases, and the good results are said to be permanent; but this greatly depends on the patient, who must occasionally make use of the means which were first used to cure him.

Testing the Purity of Air (*Dublin Journal of Medical Science*, Nov. 1872).—Dr. R. Angus Smith has devised a simple form of apparatus by which any person of ordinary intelligence and education might readily determine whether or not the amount of carbonic acid in the air of a place was above the normal or any other proportion. Baryta-water is a most sensitive re-agent for the detection and precipitation of carbonic acid. If half an ounce of baryta-water, containing about 0.08 gramme of baryta, be placed in a clear glass bottle having a capacity of 640 cubic centimetres (22 ounces), and the latter be well shaken, a turbidity (produced by a precipitation of barium carbonate) will be observed, if the proportion of carbonic acid in the air be 0.04 per cent.,—that is to say, the 0.2515 cubic centimetres of carbonic acid contained in the bottle will unite with the barium of the baryta-water, and form 0.00224 gramme of insoluble barium carbonate in half an ounce of water. The precipitate obtained renders the liquid turbid, but not quite opaque; it may be described as translucent. If a bottle of the capacity of 154 cubic centimetres (5.42 ounces) be employed instead of one of 640 cubic centimetres, no turbidity is produced in the baryta-water; on the other hand, if the bottle contain 44 ounces, or the air 0.08 of carbonic acid, the precipitate is twice as abundant. It is easy, then, by making an experiment in the pure open air, to observe the density of the turbidity caused by shaking half an ounce of baryta-water in a closed bottle or jar of 22 ounces capacity; and if, on repeating the experiment in a room, the turbidity is increased, then it is to be concluded that the carbonic acid is in excess and the air impure. Any medical officer of health or hospital physician might, by the aid of a few clear glass bottles of different sizes and a supply of baryta-water (lime-water might be substituted for baryta-water), easily ascertain the proportion of carbonic acid in the atmosphere of the places under his charge. A little practice would soon enable him to discriminate between the precipitate given by 0.04 and 0.08 per cent. of carbonic acid in the air. As houses practically never have as pure air as the tops of mountains, we may rest satisfied when a bottle of 3.78 ounces avoirdupois capacity gives no precipitate when half an ounce of baryta-water is shaken up in it. The air under such circumstances may contain 0.06, but cannot include 0.07, per cent. of carbonic acid. If lime-water be used, then half an ounce of it (containing 0.0195 gramme of lime) is to be shaken up in a 10½-ounce bottle, and it will remain clear if the carbonic acid be below 0.07 per cent.

Borax and Nitrate of Potassa for Loss of Voice.—Dr. John W. Corson, of Orange, N.J., in the *N. Y. Medical Record* of January 1, 1873, gives a number of cases, and then says,—

"For clearness and convenience, we may sum up the results of our experience in the following brief conclusions:

"1. That in sudden hoarseness or loss of voice in public speakers or singers, from 'colds,' relief for an hour or so, as by magic, may often be obtained by slowly dissolving and partially swallowing a lump of borax the size of a garden-pea, or about three or four grains, held in the mouth for ten minutes before speaking or singing. This produces a profuse secretion of saliva, or 'watering' of the mouth and throat. It probably restores the voice or *tone* to the dried vocal cords, just as 'wetting' brings back the missing notes to a flute when it is too dry.

"2. Such 'colds' may be frequently 'broken up' at the very commencement; and this restorative action of the borax to the voice may be materially aided by promptly taking, the evening previous to a public effort, dissolved in a glass of sweetened water, a piece of the nitrate of potassa, or 'saltpetre,' a little larger than a garden-pea, or about five grains, on going to bed, and covering with an extra blanket. The patient should keep warm next day. This both moistens the dry throat and further relieves the symptoms of 'cold' and slight blood-poisoning from suppressed perspiration, by reopening the millions of pores of the skin more or less closed by cold.

"3. These remedies have the three recommendations of being easy to obtain, convenient to carry in travelling, and perfectly harmless.

"4. They are nearly or quite useless in the actual cure of long-continued chronic disease of the throat, or acute inflammation or 'tonsillitis,' both of which require other appropriate treatment."

To Kill Lice (*Edinburgh Medical Journal*, Nov. 1872).—All kinds of lice and their nits may be got rid of, *tuto*, *cito*, *et jucunde*, by washing with a simple decoction of stavesacre (*Delphinium staphisagria*), or with a lotion made with the bruised seeds in vinegar, or with the tincture, or by rubbing in a salve made with the seeds and four times their weight of lard very carefully beaten together. The acetic solution and the tincture are the cleanliest and most agreeable preparations, but all are equally efficacious in destroying both the creatures and their eggs, and even in relieving the intolerable itching which their casual presence leaves behind on many sensitive skins. The alkaloid delphinia may be also employed, but possesses no advantage, except in the preparation of an ointment, when for any reason that form of application should be preferred.

MISCELLANY.

Power of Imagination.—Dr. D. H. Tuke, in his recent work, "Illustrations of the Influence of the Mind upon the Body," etc., quotes an anecdote given by Mr. Braid, that "he requested four gentlemen, in good health, and from 40 to 56 years of age, to lay their arms on a table with the palms of their hands upwards. Each was to look at the palm of his hand for a few minutes with fixed attention, and watch the result. Entire silence was enjoined. What happened? 'In about five minutes, the first, one of the present members of the Royal Academy, stated that he felt a sensation of *great cold* in the hand; another, who is a very talented author, said that for some time he thought nothing was going to happen, but at last a *darting, pricking* sensation took place from the palm of the hand, as if electric sparks were being drawn from it; the third gentleman, lately mayor of a large borough, said that he felt a very uncomfortable sensation of heat come over his hand; the fourth, secretary to an important association, had become rigidly cataleptic, his arm being firmly fixed to the table.'

"It would be difficult to determine in these instances by what train of thought these different results came to pass; whether each imagined that such and such effects would be produced by the process, or whether an accidental condition of the hand at the moment caused certain very slight suggestions, which were intensified by the attention directed to them. Probably the former; but one thing is certain, that had Mr. Braid suggested other effects, instead of preserving silence, the character of the sensations would have been greatly modified."

Newspapers.—*The Edinburgh Medical Journal* says, "One of the recent deliverers of the introductory lectures in London attacked the *Daily Telegraph*, warning the students not to read it, and got most mercilessly mauled by that journal as his reward; but Professor Max Müller is even bolder, for he attacks the whole genus, and says that the daily perusal of a newspaper for five years would break down the most vigorous memory in the world; the constant succession of fleeting impressions allowing none to take strong hold, and thus enfeebling the retentive power. The *Lancet* very properly points out that it is not merely the memory that is thus impaired, but also the judgment, which, by a rapid transition from subject to subject, becomes perfunctory in its exercise; the faculty of sustained attention is impaired, and a superficial, uninquiring, and far from independent habit of mind is induced. Ephemeral literature is very often recommended as an occasional relief from severer studies, and, judiciously practised, the advice may be productive of good; but of the truth of our contemporary's remarks there can be no doubt, and all wise students should reduce the perusal of ephemeral literature to a minimum."

℞.—A correspondent of the *Lancet* says, "It is an interesting fact, and one of which very many of your readers may be unaware, that the prefix which we daily place at the head of our prescriptions, imagining it to be the letter R as representing the word *recipe*, is in reality a relic of superstition. To planetary influence from the most ancient periods the very successful effects of the healing art were ascribed, and it was usual to prefix to receipts the symbol of the planet under whose reign the ingredients were to be collected. The astrological symbol of Jupiter was subsequently invariably employed, and has now been disguised by the addition of the down stroke, the cloven foot (℞) alone remaining as the tell-tale of its superstitious origin. Such is the history of what we usually prefix at the head of every prescription, and is worth knowing as an interesting fact, a link still binding together the present and the past, a relic of the dark days of physic."

Effects of Tobacco.—The *Medical Press and Circular*, in the course of an article on this subject, says M. Bertillon found that 102 of the pupils attending the Polytechnic School of Paris smoked tobacco, while 58 did not. Arranging the two categories in the order of merit, according to the results of examinations, he found that, in every grade, non-smokers held the higher rank, and that the smokers deteriorated from the time they entered until they left the school. Facts like these induced the Minister of Public Instruction to issue to the directors of colleges and schools throughout France a circular, forbidding tobacco to students, on the ground that it checked their physical and intellectual development. The editor says, "Among ourselves the habit is getting too common. . . . . But how is the habit to be stopped, *when meerschaum pipes are even given for prizes in Sunday-schools?*"

The Yale Medical School.—The *College Courant* says, "We see by the last catalogue that provision has been made in the plan of the new hospital building, at New Haven, for the accommodation and advantage of the Yale Medical School. Such a spirit is as pleasant as it is wise. The efficiency of the Medical School directly affects the success of the hospital management, but we feel the accommodation to the college is dictated as much by a friendly feeling towards it as by an enlightened selfishness. We are glad to see such a cordial spirit developing between the citizens and the college, for the idea that there is an irrepressible conflict between 'town and gown' has lived fully long enough and done fully enough mischief."

Politics and Medicine.—According to the Paris correspondent of the *New York Daily Times*, evident radicalism prevails at the Paris School of Medicine among the students and professors, while anything like communist language brings down the house. So well is the audience known, that professors are said to introduce politics designedly and for the purpose of winning popularity.

Dr. Max von Pettenkofer has been called from the chair of hygiene, in Munich, to the same in the Hochschule at Vienna.

KITCHEN-RANGE EXPLOSIONS.—One of those singular "epidemics" of a certain kind of accident, often noticed, has just occurred in this country. In various regions there have been, between the 28th of December, 1872, and the 4th of January, 1873, about a dozen explosions of the boilers of kitchen-ranges; several of them attended with the loss of one or more lives. Of course the cold weather and the consequent freezing of the pipes may be assigned as the general cause of these disasters; but why they should have been so rare in former winters and so numerous in this can hardly be explained.

A TELEGRAPHIC dispatch, dated London, January 6, says, "In the case of the ex-Emperor Napoleon, a second operation was performed at noon to-day. The patient was put under the influence of chloroform. The difficulties were unusually great, but the results were not unfavorable. The Emperor suffered much, but rather from constitutional disturbance than from the effects of the operation. His strength holds out well."

[Our readers will all know by this time of the fatal result in the Emperor's case, which took place January 9, an hour or two before a third *séance* of lithotrity was contemplated.]

COLLEGE OF PHYSICIANS OF PHILADELPHIA.—At the stated meeting of this body, held January 1, the following officers were elected for the year:

President, Dr. George B. Wood.
Vice-President, Dr. George W. Norris.
Secretary, Dr. John H. Packard.
Treasurer, Dr. J. Rodman Paul.
Recorder, Dr. J. Ewing Mears.
Librarian, Dr. Robert Bridges.
Censors, Drs. Isaac Hays, Joseph Carson, Lewis Rodman, Edward Hartshorne.
Councillors (for three years), Drs. W. S. W. Ruschenberger and James H. Hutchinson.

STATISTICAL.—The *Wiener Med. Presse* of Nov. 17 says, "There were in Italy, between 1864 and 1870, 55,049 deaths from other than natural causes, of which 42,870 were accidental, 17,090 by murder, 4984 by suicide, 184 by judicial procedure, and 22 by duels. The greatest number of suicides took place in Calabria, Sardinia, and Lombardy; the smallest in the Basilicate, in Emilia, and in Liguria. The deaths by intemperance were most numerous in Piedmont, Lombardy, and Venetia."

APPOINTMENTS.—Drs. Wharton Sinkler and Horace Y. Evans have been appointed on the medical staff of the Episcopal Hospital, in this city, to fill the vacancies caused by the resignations of Drs. A. M. Slocum and J. Cheston Morris; and Drs. Bennett and Henry were elected to serve on the dispensary staff.

Dr. James Markoe has been appointed one of the physicians to Girard College, in the place of Dr. Hollingsworth, deceased.

EVEN so late as 1680 a pound of cinchona cost in England eight pounds sterling. But it had its enemies at the same time. In 1729, Johann Canold, a physician of Breslau, declared upon his death-bed that he would sooner die than owe his life to an agent opposed to all his principles.

THE census of France for 1872, just completed, shows the population to be 36,102,921, a decrease of 366,935 since 1866. The decrease is attributed mainly to the war, besides which causes there have been many fatal cases of smallpox and a falling-off in the number of marriages.

DR. WILMER WORTHINGTON, of West Chester, Pa., an old and highly-esteemed practitioner of medicine, for several years past Speaker of the lower house of the State Legislature, is very ill at his home, and fears are entertained that he cannot recover.

PROFESSOR KLOB is to be transferred from Vienna to Prague, to take the chair of Pathological Anatomy vacated by the death of Prof. Treitz, whose suicide we noted some time since.

DR. CARL RUDOLPH BRAUN, the distinguished Professor of Obstetrics and Gynæcology at the University of Vienna, has been raised to knighthood, with the title of "Fernwald."

MORTALITY OF PHILADELPHIA.—The interments reported at the Health Office for the week ending Jan. 11, 1873, were 325; 200 adults, and 125 minors. 10 were of bodies brought from the country; making the mortality of the city 315. Among the causes of death were:

Consumption of the Lungs	41
Other Diseases of the Respiratory Organs	70
Diseases of the Circulatory Apparatus	21
Diseases of the Brain and Nervous System	42
Diseases of the Digestive Apparatus	21
Hernia	3
Zymotic Diseases	18
Typhoid Fever	4
Casualties	10
Exposure	1
Cancer	2
Intemperance	3
Suicide	1
Debility (including "Inanition" and "Marasmus")	30
Still-born	21
Old Age	16

(The interments reported for the week ending Jan. 13, 1872, were 504.)

THE meteorological record kept at the Pennsylvania Hospital was as follows:

	THERMOMETER.		BAROMETER.
	Max.	Min.	(2 P.M.)
Jan. 5	37.0°	31.0°	29.84 in.
" 6	36.0	26.5	30.33 in.
" 7	31.5	21.5	30.49 in.
" 8	33.0	20 0	30.16 in. (Rain.)
" 9	33.0	22.0	30.11 in.
" 10	28.0	18.0	30.28 in.
" 11	16.0	8.0	30.50 in.

SATURDAY, JANUARY 25, 1873.

ORIGINAL LECTURES.

LECTURES
ON THE SURGERY OF THE NARES, LARYNX, AND TRACHEA.

BEING THE MÜTTER LECTURES FOR 1872.

Delivered before the College of Physicians of Philadelphia,

BY J. SOLIS COHEN, M.D.

Reported by R. M. BERTOLET, M.D.

LECTURE I.

EXAMINATION OF THE PARTS.

INSPECTION of the throat by the ordinary means of depressing the tongue permits an examination of more or less of the pharynx and of the epiglottis, and occasionally a glimpse of the upper margin of the larynx; but, as usually performed, it exposes only a small portion of the pharynx. The best method of obtaining the most extensive view possible consists in using a tongue-depressor long enough to reach the base of the tongue and to press it down without slipping, and to stand by the side of the patient rather than in front of him; then, as we look into the throat, which must be well lighted up, we cause the patient gradually to depress the chin upon the breast, and at the same time we press the tongue more and more downward and forward upon the floor of the mouth with a firm though gentle pressure. In this way we can almost invariably expose the entire pharynx, and, with it, more or less of the free surface of the epiglottis. If the patient does not bear the manipulation well, we can depress first one half of the tongue and then the other. Sometimes by titillating the epiglottis with the end of the tongue-depressor we can cause the momentary elevation of the entire larynx, and gain a view of its upper circumference. To examine the upper portion of the pharynx, the head is thrown back, the tongue merely kept from bobbing up by slight pressure upon it, and the soft palate raised by voluntary inspiration. Sometimes a blunt hook is passed behind the palate, in order to raise this structure and thus expose a greater surface of the pharynx to view.

To inspect the interior of the larynx and trachea, we now avail ourselves of little mirrors, which are placed within the cavity of the mouth and held in such a position as to reflect light into these structures and thus present us with an image of the parts illuminated. If the mirror is held behind the palate, so as to illuminate the upper walls of the pharynx and the posterior outlet of the nasal passages, we have in like manner a view of the image of these structures.

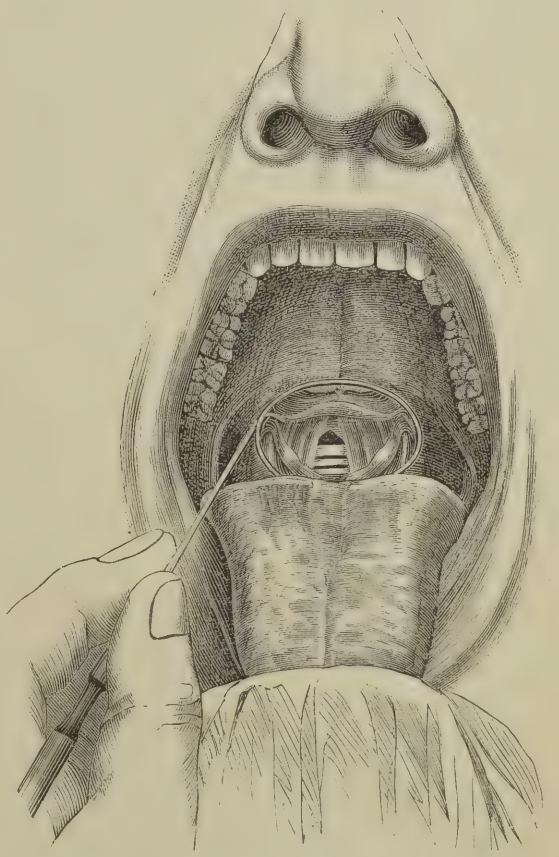
The anterior portion of the nasal passages is examined by the aid of some suitable contrivance for spreading the nostrils and thus permitting illumination of the passages.

The method of examining the larynx and adjacent parts by reflection is known as laryngoscopy; that of examining the region of the posterior nares and the upper portion of the pharynx is called rhinoscopy. As is well known, these methods have been perfected of late years only, and, though deemed of great value by the profession generally, have not yet come into constant use. It is to be hoped that they will eventually be as commonly and universally employed as are auscultation and percussion.

LARYNGOSCOPY AND RHINOSCOPY.

The history of the invention was merely illustrated by the lecturer's extensive collection of the various instruments that have been devised from time to time and employed for the examination of these parts. Among the earlier attempts to obtain an inspection of the laryngeal cavity were mentioned and illustrated those of Bozzini with his cumbersome specula, Warden's unwieldy glass prisms, and Babington's with the simple dental mirror. The earliest attempt was made by Levret, in 1743. Without entering into the details of the controversy regarding priority of discovery be-

Fig. 1.



THE LARYNGOSCOPIC MIRROR IN POSITION.

tween Türck and Czermak, the lecturer stated that it was mainly due to the efforts of both of these indefatigable workers that laryngoscopy and rhinoscopy at once gained recognition as valuable and indeed indispensable aids to the practitioner. This is not, however, the occasion to enter into a detailed history

of these subjects. Those who are interested can find all the information to be obtained in the various monographs. Our present object is to discuss briefly the most convenient method of manipulation.

In making these examinations it is necessary to have a good illumination, either from the direct or reflected rays of the sun, or from a good artificial light.

The operation consists essentially in introducing a small mirror within the cavity of the mouth in such a manner as to reflect the light upon the parts to be examined, so that we can see their image in the mirror. The most convenient form of mirror for this purpose is a circular looking-glass about an inch in diameter, well silvered, and firmly soldered to a stem at an angle of about 120°. In some cases a much larger mirror can be used, and in others it is necessary to employ a smaller one. Where the space is encroached upon by enlarged tonsils, it is necessary to use an oval mirror narrow in its transverse diameter. The diagram (Fig. 1) represents the appearance of the mirror in position, and the character of the image reflected from it in a laryngoscopic examination. The head of the patient is erect or slightly bent backwards, the tongue protruded, and prevented from slipping back by being held with a handkerchief or napkin. The handle of the mirror is seized much as one would seize the handle of a pen, with the mirror pointing upwards, its reflecting surface being horizontal and looking downwards; and the hand is moderately extended on the wrist, as seen in the diagram (Fig. 2). The

Fig. 2.

Manner of Holding the Mirror when about Introducing it.

mirror is then passed to the posterior portion of the pharynx, without touching the tongue, and the uvula and soft palate gently raised upon it, the wrist being flexed so as to render the handle of the mirror horizontal and bring the plane of its reflecting surface in a direction looking downwards and forwards. The success of the manœuvre depends upon avoiding contact with the tongue, and keeping the mirror steady so as not to tickle the parts. Pressure of the lower border of the mirror upon the pharynx is well borne, and affords a sufficient support to the instrument.

The small reflecting mirror is heated over a flame for a moment or two, to warm it so that the vapor of the breath may not condense on its surface, an occurrence which would disperse the rays of light and render reflection impossible. Care must be taken not to heat the mirror to such a point as to burn the patient. If the mirror is watched while being warmed in this way, it will be seen that condensed moisture at once deposits, and immediately evaporates from circumference to centre. The moment the mirror is clear it is fit for use. This plan is much better than that of dipping the mirror into hot water.

When the mirror is in position, we recognize in it an image of the larynx and contiguous structures. The oblique position of the mirror throws the image of these structures (base of tongue, epiglottis, etc.) which are in front in the patient to the upper part of the mirror, and those which are behind (arytenoid cartilages, posterior wall of pharynx, etc.) to the lower part of the mirror; these parts appearing reversed,—that is to say, the epiglottis, tongue, etc., which are really anterior, appear as if they were posterior, and the arytenoids, etc., which are really posterior, appear to be anterior, in the image. It requires a little consideration at first to render this reflection intelligible, but after a short study the relations of parts in the subject and in the image can be promptly appreciated.

IMPEDIMENTS TO EXAMINATION.

With ordinary care and a moderate amount of skill, a satisfactory examination can be made at the first attempt, except in very rare instances. If the impediments to examination depend upon inability or unwillingness to open the mouth, we may, if necessary, distend the mouth by a gag,—such as is used when operating for cleft palate,—or we may introduce a short plain glass speculum and pass the mirror through it. If the tongue rises too much in the mouth, we may control it by placing the finger, a penholder, or something of that kind upon it, as a sort of reminder, to steady it as it were. If the palate and pharynx are very sensitive, we may be compelled to pass the mirror higher up and make its reflecting surface more horizontal, so as to throw the light upon the larynx without touching any of the parts; but this is difficult and constraining; and it is therefore better to accustom the parts to bear the contact of the mirror, by repeatedly touching them with it. The application of astringent sprays, or of morsels of ice, and the inhalation of a few whiffs of chloroform, are methods which promptly control undue irritability; but their use is seldom called for, the irritability being created most frequently by the trembling hand of the manipulator.

If the tonsils are enlarged to such an extent as to preclude the use even of an oval or a very small mirror, their excision becomes necessary.

If an elongated uvula presents an obstacle, it should be shortened by excision, if the use of astringents fails, as is almost always the case, to retract it.

If a depressed epiglottis prevents the reflection of the light to the interior of the larynx, it is to be pulled forward by a blunt bent wire, probe, or whalebone rod, passed behind it.

If the respiration of the patient is spasmodic or hurried, it must be corrected before proceeding to the examination.

(To be continued.)

ORIGINAL COMMUNICATIONS.

SOME CASES OF GUNSHOT WOUND.

BY JOHN H. PACKARD, M.D.,

One of the Surgeons to the Episcopal Hospital, Philadelphia.

AN important question in many cases of gunshot wound is, whether probing should or should not be resorted to in order to determine the presence or the situation of balls or other foreign bodies. It will be remembered that in a recent murder trial in New York an attempt was made to ascribe the death of the victim to violence done in this way by the surgeons; and cases occur in which such a plea might assume, and justly, great weight.

The authority of writers on military surgery has generally been sufficiently decided in favor of this procedure in wounds of the extremities, and against it in those involving either of the great cavities. The question really turns upon the necessity or practicability of extraction. If the missile has done all the harm it is likely to do, or if it is evidently so lodged that its removal would involve either danger or great difficulty, it would be worse than folly for the surgeon to persist in satisfying his curiosity as to where it is or how it got there.

The cases now to be detailed are given in support of this view.

Case I.—In the summer of 1871, on a very hot night, I was called, at about 1 A.M., to see Mr. R., æt. 22, who had been shot in the chest. The circumstances of the affair were very curious. Mr. R. was sleeping in the same room and bed with his friend Mr. B., at the house of the latter, whose family were out of town. They were *both* wakened by the report of a pistol, and Mr. R. found himself suffering intensely from a wound just below the clavicle, on the right side, between the first and second ribs, and about two inches from the median line. The shock was very severe.

When I arrived at the house, about twenty minutes after the shooting, I found Dr. Leach already in attendance. Mr. R., excessively pale, was floundering about in bed, shrieking and uncontrollable, slight hemorrhage taking place from the orifice made by the ball. There was some expectoration of frothy florid blood. With much difficulty, Dr. L. and myself suceeeded in quieting him sufficiently to administer a small quantity of brandy, with a few drops of laudanum; and after a few doses of this, at intervals of fifteen minutes, he became sufficiently calmed to give his account of what had happened. Subsequently he showed great fortitude and resolution. The state in which we found him had been simply the effect sometimes seen in military practice from gunshot wounds even of slight moment.

It appeared probable that Mr. B., whose house had been robbed some time previously under very painful circumstances, had been roused by a noise, got up, took his pistol, which he kept loaded in his bedroom, and then lay down to listen; he fell asleep, when a movement of his bedfellow again partially roused him, and he sprang up; Mr. R. rising at the same moment, Mr. B. fired, thinking him a burglar.

Dr. Hunt was, at our suggestion, called in for further consultation soon after the accident happened.

Until about 5 P.M. of the next day, Mr. R. continued in an extremely critical condition, blanched, cold, and pale, with an excessively rapid pulse, pinched features, and labored respiration.

At the time above mentioned, there was a favorable change in Mr. R.'s symptoms. He had dulness on percussion over the upper two-thirds of the right chest posteriorly, with absence of respiratory sounds; but in front the lung seemed clear. His pulse still remained at about 120 per minute, and feeble; but his mind was clear, and his courage good.

From this time forward he steadily improved under very simple treatment, but with careful watching and good nursing, and in four weeks he was able to be taken home. The dulness on percussion over the back of the right lung cleared day by day. Soon afterwards he began to go about, and is now—eighteen months having elapsed—in perfect health, a gymnast, as before, and in every way quite well.

Remarks.—It would be difficult to name any more dangerous locality for a gunshot wound, not immediately and necessarily fatal. The ball must have gone close to the innominate artery and vein and the right pneumogastric and phrenic nerves. We thought it probable that the second intercostal artery was wounded, and that from this an effusion of blood had taken place in the cavity of the pleura, causing the percussion-dulness and the want of respiratory sounds. During the first seventeen hours his condition was so critical that we could not think of any attempt to find the ball, and subsequently it was equally out of the question to risk interfering with the favorable progress of his case by probing. Moreover, the ball had already done, as it seemed to us, all the harm it could. The probability is that it lodged in the loose connective tissue beneath the right scapula, and that it is encysted there to this day. The calm fortitude and courage of the patient, enabling him to submit quietly to the restraint we imposed on him, had much to do with the happy issue of the case.

Case II.—James C., æt. 31, born in Ireland, and a laborer by occupation, was admitted to the Episcopal Hospital in the evening of September 1, 1871. He stated that he was walking, after supper, with a friend on the "Connecting Railroad." At about 8½ o'clock a peach train stopped near them, because of some disarrangement of the engine. He and his companion approached an open door, and the inmate of the car asked his companion what was his business, and used abusive language. His companion became frightened, and ran off. C. continued standing by the car, and was shot by the railroad hand. He was brought to the Episcopal Hospital at about 11.40 P.M. There was scarcely any external hemorrhage, and no symptom to indicate any internal. The wound was three and a half inches directly above the umbilicus. When probed, the direction of the ball seemed to incline obliquely from left to right and slightly downwards. He was put to bed, given an ounce of whiskey, and a hypodermic injection of morphia to the extent of about one-third of a grain; was then ordered one teaspoonful of the officinal solution every two hours. Vomited a short time after admission.

September 2.—Pulse good; pain much relieved; dose of liq. morph. increased to two teaspoonfuls every two hours.

September 3.—Pulse good; tongue clean; pain much reduced. Dose reduced to one teaspoonful, with the

same interval; also ordered f℥i of whiskey three times a day.

September 4.—Patient exhibited symptoms of acute peritonitis. Decubitus marked; pain severe; great anxiety of countenance. Ordered twenty-five leeches to abdomen, followed by a turpentine stupe and then a poultice.

September 5.—Much relieved.

September 9.—Had a passage from his bowels.

September 11.—Bowels had discharged freely. No bullet found in fæces. Morphia suspended.

The fæces were examined until the day of his discharge (October 1), but no bullet was found. He went away feeling perfectly well.

Remarks.—In this case also it seems most likely that the bullet lodged somewhere in the connective tissue, the intestines yielding to its passage. What special organs were endangered, it is impossible now to say.

I may remark that the probing was all done before I had seen the man at all, and that, in my opinion, it was not only useless, but dangerous, so soon as the fact was ascertained that the bullet had traversed the anterior wall of the abdomen.

Case III.—On the 3d of July, 1872, a man, æt. 30, was brought into the Episcopal Hospital, having been shot in the right eye by a policeman, with a pistol. The ball was supposed to have entered the brain. The man's symptoms were those of collapse. He rallied, however, and was seized with nausea and vomiting. The resident surgeon, standing by, heard some solid body strike the basin, and found it to be the ball, flattened and bent out of shape. No untoward symptoms followed; but the eyeball suppurated, and on the 11th, eight days after the injury, I excised it. Everything went on well, and the patient eloped from the hospital about two weeks later, to escape re-arrest by the police.

I have since seen him, and he is perfectly well.

Case IV.—David B., a policeman, æt. 48, shot himself in the head with a pistol, July 4, 1872. He was brought to the Episcopal Hospital the next day. The ball had entered almost exactly at the centre of the forehead, making a small orifice, in the skin around which there were imbedded numerous grains of powder. A probe was carefully passed backwards about three and a half inches, without meeting with the slightest resistance. The ball was not felt. He showed no signs of cerebritis, but was melancholy, and expressed himself determined to die.

He lived, almost without symptoms except mental excitement and delirium, for sixty-eight days, his death being the result of exhaustion.

An autopsy was made on the 14th of September, four days after death, the head only being examined. He was greatly emaciated.

The wound in the forehead was a very little to the left of the median line. Encysted at the hole in the skull there lay two pieces of the bullet and a little bit of bone. Several bruises, or, at least, ecchymoses, were noted in the scalp, one very large one a little above and behind the left ear.

The calvaria was very much congested. All over the surface of the left hemisphere there was effusion of lymph, and the brain was very full of blood. The track of the bullet seemed lined with consolidated brain-matter, and the bullet itself lay imbedded in softened and bloody brain-matter, close to the upper surface of the brain, near the longitudinal sinus, having apparently gone directly backward until it came in contact with the dura mater. Below, and corresponding to the large bruise of the scalp before mentioned, there was a very considerable effusion of blood, perhaps partly absorbed. A good deal of bloody serum was effused in both lateral ventricles.

The cerebellum was congested and softened.

Remarks.—The probing in this case was done with the utmost care and gentleness,—once only, and then because we could not otherwise know that the ball had passed out of reach. Its result might have been valuable; for had this man been accidentally shot, and willing to second any attempts for his relief, I would have placed him on his face, with careful mechanical support arranged for the head, with a view to letting the ball gravitate towards the orifice of entry. As it was, we could hardly keep him in bed at all, restraint, by means of handcuffs fastened to the bedstead, being necessary almost the whole time.

The bruise at the left side of the head was the result of a blow from a club in the hands of a prisoner, some weeks before the man shot himself. The medico-legal question arose, how far this blow could be assigned as the cause of mental aberration, and thus of the fatal act. The grand jury decided, in my opinion very properly, that there was no distinct evidence of connection between the two events.

1928 Spruce Street, January, 1873.

REMARKS ON SOME OF THE PHYSIOLOGICAL AND THERAPEUTICAL ACTIONS OF VERATRUM VIRIDE.

Read before the Medical Library and Journal Association of New York.

BY EUGENE PEUGNET, M.D.,
New York.

(Continued from p. 247.)

II. Its Mode of Administration.—The preparation of this valuable remedy has led to an elaborate and varied series of chemico-physiological investigations. Although Messrs. H. W. Worthington, Joseph W. Richardson, Dr. S. R. Percy, and M. Bullock have worked earnestly, they have all failed, with the exception of Mr. Worthington, who demonstrated the existence, in the root, of an alkaloid, the veratroidia, and of Mr. Bullock, who demonstrated the existence of a second alkaloid, the viridia. My investigations confirmed the existence of these alkaloids, and demonstrated their distinct chemical reactions and physiological actions; further, that the remarkable sedative powers of the plant were due to the *combined action* of the alkaloids. Unfortunately, they were not conclusive enough to demonstrate the exact proportion of each alkaloid necessary for that purpose, and, like my predecessors, I was compelled to fall back on its tincture and its fluid extract.

Why? Because it is a recorded fact that in our researches for the active principles of vegetable remedies we find that, although chemistry enables us to separate the active principles of plants, physiology demonstrates that the action of these principles frequently varies from that of the plant

itself. Yet this is not surprising; for do we not in the preparation of our pharmaceutical compounds endeavor to, and do we not actually, effect chemical combinations of mineral substances in order to obtain either an increased or a modified action? Is it therefore surprising that this chemical combination should exist in organic substances?

The active principles of plants generally exist as gallates or tannates, and are held together in intimate combination; it is in that form that we should endeavor to obtain them: unfortunately, our chemical knowledge does not enable us to do so as yet, save by extracting the active principles of plants with alcohol.

Numerous formulæ have been suggested, but there are only two in vogue at present,—Norwood's tincture and the fluid extract.

These preparations are not always reliable, owing to the careless manner in which the root is gathered, and also to the length of time it has been kept. To obviate this, and to obtain a saturated tincture of uniform strength, I consider the following rules imperative:

1. The root should be gathered immediately before the plant blossoms, as it is then in its full vigor. About the middle of May is thè appropriate time for this latitude.

2. The root should be allowed to dry spontaneously for forty-eight hours, the small rootlets then carefully removed, and the root ground or *bruised.*

3. The best formula is Norwood's, which has been adopted in the United States Dispensatory; with this modification, however, that the bruised root should be allowed to macerate for at least forty-eight hours before being placed in the percolator.

Experience and study have taught me that this is the best method for preparing tinctures, whether of the blossoms, leaves, stems, barks, or roots, and that all tinctures should be prepared on the native soil of our pharmaceutical plants; thus obtaining a uniform strength of tinctures.

III. Its Hypodermic Administration.—As it has so far been impossible to separate the alkaloids in their natural combination, I have made the following experiments, with—

1. The alkaloids extracted from the root by means of acetic acid;

2. Norwood's tincture, to which an acid reaction was given with acetic acid, then an equal volume of distilled water added to it, and the whole evaporated on a water-bath till all the alcohol was expelled, thus reducing the mixture to the original volume of the tincture, then separating the precipitated resin by a filter;

3. By preparing gallates and tannates of the alkaloids.

The first two produced such irritation on my arm, as well as on animals, that I do not consider the practice advisable. This irritation is due to the veratroidia, and my experience with it will probably account for the hypodermic injection of veratria having been practically abandoned in France.

The gallates and tannates are insoluble salts, and therefore I did not experiment with them.

The viridia alone is not irritant, but it is *inert as a sedative.*

Veratrum viride is not so much in vogue as formerly, owing to the uncertainty of its preparations, to its misapplication, and to its disagreeable and even somewhat alarming effects.

The objection to the uncertainty of its action is easily guarded against.

The one against its misapplication lies in the power of every practitioner to obviate; that is, accuracy of diagnosis, a proper appreciation of the therapeutical applications, and a proper knowledge of its physiological action.

As to its disagreeable and alarming effects. The first are easily guarded against by giving a few drops of Magendie's solution with it, which is rarely necessary after the first dose. For children, a few drops of paregoric will answer. In reference to the latter, they have been, I am inclined to believe, greatly exaggerated, and they are in a great measure due to the manner in which it has been generally administered, that is, five- to six-drop doses hourly, and increased *guttatim.* Although the remedy is not cumulative in its sedative action, it has a decided action on the pneumogastric nerve, and through this action it causes nausea and vomiting; but if we administer a full dose—ten to fifteen drops—we have at once a decided sedative action, and we can regulate it by a proportionate reduction of the dose, and a proportionate interval between each one. Whilst I have seen unpleasant effects induced by increasing the dose *guttatim*, I have never seen any unpleasant effect from adopting the opposite course.

I know of no agent in pharmacy which is more potent and decided in its action as an arterial sedative and a depressant of caloric. It acts much more rapidly than aconite; moreover, its action is entirely different: aconite acts primarily on the spinal centres, and its secondary action on the vaso-motor system is twofold; primarily in small doses it acts on the cardiac plexus, causing a contraction of the vessels, diminishing the flow of the blood; secondarily, in three- to five-drop doses it causes a dilatation of the blood-vessels, and the rapidity of the circulation is greater. Hence its therapeutical application under the accepted view of the phenomena of inflammation would be due to its primary action and in small doses; but I must confess that I have never been able to see its decided action on the circulation in the more acute inflammatory affections, and in the dynamic fevers its use is certainly contraindicated; whilst if the accepted view of the phenomena of inflammation is correct, we should endeavor to reduce the increased action of the circulation, and to diminish the temperature, which can only be done by paralyzing the vaso-motor nerves, and that action appertains *a fortiori* to veratrum.

The action of aconite is *par excellence* in febrile reactions with *peripheral nerve-pains*, in neuralgia involving the peripheral nerve-expansions, upon the local and dermal hyperæmia due to an arthritic diathesis; thus demonstrating its special and primary action on the spinal nerve-centres, by diminishing the hyperæsthesia.

PHILADELPHIA
MEDICAL TIMES.
A WEEKLY JOURNAL OF
MEDICAL AND SURGICAL SCIENCE.

The Philadelphia Medical Times is an independent journal, devoted to no ends or interests whatever but those common to all who cultivate the science of medicine. Its columns are open to all those who wish to express their views on any subject coming within its legitimate sphere.

We invite contributions, reports of cases, notes and queries, medical news, and whatever may tend to increase the value of our pages.

All communications must bear the name of the sender (whether the name is to be published or not), and should be addressed to Editor Philadelphia Medical Times, care of the Publishers.

PUBLISHED EVERY SATURDAY BY

715 and 717 Market St., Philadelphia, and 25 Bond St., New York.

SATURDAY, JANUARY 25, 1873.

EDITORIAL.

THE REPORT OF THE SURGEON-GENERAL OF THE NAVY.

SOME weeks since, we laid before our readers a summary of the leading points in the report of the Surgeon-General of the U.S. Army for the fiscal year ending June 30, 1872. We have now to notice the corresponding naval report, made by Dr. Thomas C. Palmer, Chief of Bureau of Medicine and Surgery, to the Secretary of the Navy.

The body of the report itself is composed largely of estimates for the fiscal year to begin July 1, 1873, and of recommendations in regard to matters connected with the service. The total disbursements to be provided for in the way of salaries, surgeons' necessaries and appliances, repairs and improvement of hospitals, civil establishment, contingent expenses, and printing and binding, are calculated at $196,868, against $168,732 for the present year.

Among the recommendations, the first seems highly reasonable, viz., that a profitable investment should be made of the hospital-fund (derived from a deduction of twenty cents per month from the pay of every officer, seaman, and marine), as in the case of the pension-fund. The hospital-fund amounted, on the 1st of October, 1872, to $73,910.04, which, according to the estimates, will be wholly inadequate to meet the expenses to which it would legitimately be applied. Judiciously invested, this sum might be very handsomely increased in a few years. We trust the requisite steps towards such an economical arrangement will speedily be taken.

To the next recommendation, that of the appointment of a search-clerk to attend to applications for evidence for the Commissioner of Pensions, we have only to object that it is too moderate: two or more clerks would probably find abundant occupation. In the document before us, two new hospitals are proposed, one at Portsmouth, N.H., at an estimated cost of $60,000, and one at Pensacola, Fla., to supply the place of the one destroyed during the war. Forty thousand dollars will be needed for the current repairs of the other hospitals.

Of special interest to medical men is the following passage:

"Finally, I have to implore, for the sake of our sick and wounded in line of duty, some increased facilities for purely naval education in our medical officers. The necessity of this is practically acknowledged and liberally provided for, almost to the reproach of this great nation, by foreign governments. We have official reports of those elaborate designs and developments, as presented in Appendix F" (presently to be noted). "We are shamed by them. We are reminded that *noblesse oblige*, and that the very grandeur of our country, and the pride of every citizen in it, demand at least as much cultivation in our officers as we familiarly find abroad. Every American travelling in Europe, and hailing, as we always do, the flag that represents our country, feels keenly then, what strikes him less forcibly at home, any exhibition of deficiency in his native officers. His pride revolts at the unavoidable and disadvantageous contrasts he is forced to acknowledge; so that it is familiar with us to say that if we could only once take some of our leading statesmen on a cruise, there would no longer be any difficulty in encouraging our ambition at least to equal, if difficult to excel, other nations. At home, even, we have the high example of the army, with its brilliant museum, and constantly increasing volumes of inestimable results of experience in war. The country is equally entitled to the literary and scientific labors of the navy; and its officers of all grades are eager to render them."

This passage, so far as we can understand it, is as laudable for its patriotism and its correct professional tone as it is deficient in logical sequence and argumentative force. Another paragraph much in the same style follows, and then this, which contains some curious things:

"To accomplish these ends, I propose the appropriation of $15,000 as the commencement of a school of instruction for medical officers preparing for promotion, *and as a receptacle for marine specimens in natural history voluntarily contributed;* a library; a lecture-room, with naval officers for teachers; a microscopical apparatus, *and various other appliances in*

familiar use everywhere except in our own land." (The italics are our own.)

It seems as if the Chief of Bureau must have entrusted the writing of his report to a clerk, and read the proofs carelessly, if at all. We earnestly hope his aims will be clearer to the Secretary of the Navy than the report would make them to any one previously ignorant of the matter in hand, and that they will be carried out as their importance deserves.

The appendix above referred to is an excellent account, taken from a report by Medical Inspector Shippen, of the Army Medical School at Netley, England, to which naval officers have this year been admitted.

The following statistics possess some interest:

"The average strength of the Navy—officers, seamen, marines, engineer service, and Coast Survey included—for the year 1871, as near as can be ascertained, was about 11,819.

"The proportion of cases admitted to the whole number of persons in the service was about 1.02, or each person was on the sick-list 1_{20}^{1} times during the year. The proportion of deaths to the whole number in the service was .01, and the percentage of deaths to the whole number of cases was .099, or less than 1 per cent."

OUR PUBLIC SQUARES.

EVERY autumn, the public squares of this city are closed, to be opened only late in the spring. Perhaps this is unavoidable, so long as the walks are laid with gravel; but it is none the less an absurd and grievous abuse. These parks ought to be perpetually available for invalids and children, and they could easily be made so by the laying of broad flagstones, or slate or asphalt pavements, or by in any way preparing the ground so that it would quickly dry after snow or rain.

Vastly greater expense than would be involved in such an improvement is yearly incurred by the city for far less important ends. The first cost would, after all, be the main thing; for the repairs from time to time needful for a well-laid flag or slate pavement would be but trifling, whereas the gravel has to be in fact renewed annually. We believe nearly or quite all the squares in New York have been laid with stone, and are open all the winter. As a measure for the public health, the same ought to be done in Philadelphia. Such an improvement would benefit all, rich or poor, who are now often precluded from open-air exercise by the state of the footways, and would give the squares double their present value.

PROCEEDINGS OF SOCIETIES.

PHILADELPHIA COUNTY MEDICAL SOCIETY.

THE PRESIDENT, DR. D. HAYES AGNEW, in the chair.

A CONVERSATIONAL meeting was held December 11, 1872, at 8 o'clock P.M.

Dr. O'HARA mentioned a case of obstruction of the bowels preceding labor, continuing five or six days. There was peritonitis, which was followed by a discharge of pus from the vagina. The patient has since recovered.

Dr. W. L. ATLEE thought it probable that in the case mentioned, the obstruction in the rectum was the result of post-uterine pelvic cellulitis. This opinion was based upon the fact that the labor was severe and tedious, and that the obstruction was removed after the discharge of pus from the vagina. An examination before and after the existence of the difficulty might have shown the true cause.

Dr. Atlee had met with several cases of obstinate obstruction of the bowels. He could recall to mind one of particular interest: Saturday night, July 14, 1860, he was called to see Mrs. E. C., aged 50, in consultation with Dr. D. F. Condie. For two years she had been more or less complaining, and for three weeks before he saw her, she had suffered considerable distress in the bowels. Dr. Condie saw her for the first time on Friday, the day previous, and failed in having her bowels moved, everything having been rejected from the stomach.

The abdomen was greatly distended, very tense, and drumlike on percussion. The most tender point on pressure was in the region of the left iliac fossa, but no spot of special hardness or of dulness on percussion could be made out. She was suffering great distress from pain, constant vomiting, and excessive thirst. The pulse was full, soft, and about 100 to the minute. There was every indication of obstructed bowels, as in strangulated hernia. But she had never had hernia, although she had repeatedly had lighter attacks of a similar kind.

On making a particular examination, a slight enlargement was observable in both groins, but unaccompanied by hardness or tenderness on pressure. The protuberances rolled under the fingers very much as do small femoral herniæ. Neither of them was in such a condition as to give rise to the opinion that the source of trouble originated here.

Dr. Condie had given the patient fifteen grains of calomel in the evening, several hours before the period of consultation, and it was agreed to follow this up with alterative doses of the same medicine, adding opium suppositories, and turpentine stupes to the abdomen.

Sunday morning, the 15th, Dr. Atlee and Dr. Condie saw the case again. The symptoms were not relieved. On inspecting the groins again, a slight increase of the tumor in the right side was noticed, accompanied by a semi-resonant sound on percussion, but in other respects it was entirely unlike a strangulated bowel. Treatment continued.

Sunday night.—The patient not relieved. The thirst continued extreme, and the vomiting incessant. Pulse more frequent, but still full and soft, and skin normal. The tumor in the right groin rather larger, but not tight or sensitive. It was decided to cut down upon this tumor in the morning, if the patient was not better.

July 16.—The patient still not relieved, and the general symptoms worse. The wrists and hands were cold and of a purplish tinge, the pulse smaller and more frequent, and all the symptoms more alarming. Dr. Atlee cut down upon the tumor in the right groin, and a mass of fat of the size and shape of a small egg was

liberated from a peritoneal cyst. This was traced up to the crural ring, and found to protrude through it. He now scarified this mass of fat and tore it apart, but for some time he could find nothing like intestine. He next cut the edge of the crural ring on the outside, so as to enable him to liberate more of the tumor from the ring, when he found about an inch of the intestine protruding, and so incorporated with fat that it was difficult at first to recognize it as a portion of intestine. The excess of fat was now cut away, and the bowel was returned. The little finger was next passed through the crural ring into the peritoneal cavity, and no adhesions were detected within. The bowel had a normal appearance, very unlike one that had been strangulated. The wound was closed, and the patient ordered an anodyne and brandy.

The same night the patient was found in a state of collapse, and the obstructions not removed. The wrists and hands were quite cold and clammy, and the pulse exceedingly feeble. After the operation, the patient had a frequent desire to evacuate the bowels, but passed nothing. There was also constant regurgitation from the stomach. Dr. Atlee operated now upon the tumor in the left groin, and found a similar mass of fat protruding through the crural ring. This was also unravelled, but no intestine was found. It was excised, and the ring explored by the little finger. Ordered turpentine and castor oil by the mouth and by injection, with stimulants.

July 17.—Patient died at 12.30 A.M., there having been no relief from any mode of treatment.

Autopsy, twenty-two hours after death, by Dr. Drysdale, in the presence of Drs. Condie, Atlee, and Burpee. The abdomen was greatly distended, and resonant everywhere on percussion. The walls were well loaded with adipose and muscular tissue. On laying aside the flaps, there were observed no peritoneal adhesions indicating the previous existence of peritonitis. The colon was immensely distended throughout its whole extent from the caput coli down to the lower end of the sigmoid flexure. Its vessels were greatly engorged, and throughout its whole extent it had a dark mahogany color. The transverse colon, particularly, was enormous, its diameter being at least five inches. On tracing down the colon to a point opposite the promontory of the sacrum, the dilatation was found to terminate abruptly into a very contracted portion of the bowel, which was occupied by a scirrhous deposit, beyond which, clear to the anus, about seven or eight inches in length, the bowel was normal. The small intestines from one extremity to the other were contracted and free from disease. Not a particle of gas seemed to have escaped from the colon into the small intestines. The pylorus, however, was thickened and solidified, and its orifice contracted to about one-fourth its size. The stomach was filled with fluid.

The sigmoid flexure and rectum were removed for further examination. The contracted portion embraced but a very small portion, perhaps not an inch in extent, and consisted of cancerous deposit. The mucous coat of this portion was in a state of ulceration, and at a point close above the stricture the ulcer had perforated all the coats of the bowel, except the peritoneal, and this partially, so that a very slight pressure caused its rupture. The passage through the strictured bowel was so small as scarcely to admit the flat handle of the scalpel.

The right groin was next examined The edges of the wound had become agglutinated. Upon inspecting the crural ring from within, a small knob of fat was noticed, which evidently was a portion that had been returned at the time of the operation, and near this was a red patch, like an abrasion, but no opening in the peritoneum. The finger, when pushed through the ring from without, could be carried round in every direction without discovering an opening into the peritoneum, but when directed against the abraded surface the latter was found to be attenuated. This point had evidently been closed by a recuperative process after the operation.

The left groin was also examined, but there was no indication within that the peritoneum had been perforated.

Some small hydatids of a dark color were attached to the right broad ligament. Both ovaries were atrophied. The uterus was normal. The mesentery throughout was thickened and opaque.

Dr. Atlee referred to another case of obstruction, which had occurred in his brother's practice at Lancaster, when he was a pupil in his office. Mrs. S. had been treated by various means for ten or fifteen days without relief, when upon consultation it was decided to administer quicksilver. This in the course of two or three days had the desired effect. The obstruction was removed, the quicksilver passed through her, alvine evacuations followed, and her recovery was complete.

Dr. Atlee remarked that it had always been a mystery to him how quicksilver accomplished its passage through the bowels. As it has in itself no medicinal action, it must act in consequence of its great weight; and yet, when the several convolutions of the bowels are considered, it would seem to be under the necessity of travelling at times against gravity. He could understand how it might pass from the stomach through the small intestines, and through the ileo-cœcal valve into the ascending colon, by it at times becoming as it were a fixed point upon which the peristaltic or vermicular motion of the bowels could operate in drawing certain ascending portions over it. But in the ascending colon, which is so firmly fixed in position by the mesocolon, such a result could not be expected. Still, even here, a recumbent position of the body would aid its transit. If he were to administer this agent, he would order his patient to occasionally change the position of the body in order to facilitate its progress through the alimentary canal.

Another case, referred to by Dr. Atlee, also occurred in the practice of his brother. Mrs. H., a corpulent lady, died of irremediable obstruction of the bowels, and, upon making a post-mortem examination, a large gall-stone was found blocking up completely the valve of Bauhin, and producing all the effects of strangulation. The gall-stone had ulcerated through the coats of the gall-bladder and of the adjacent intestine, had entered the cavity of the latter, travelled through the small intestines, and finally lodged firmly against the valve, and thus obstructed the bowels.

Dr. Atlee referred to another case of death from obstruction of the bowel, which followed some months after recovery from an operation for strangulated scrotal hernia. He operated in the spring of 1845 at Mount Hope, Lancaster County, on Mr. G. S., for strangulated scrotal hernia. The bowel had been imprisoned for ninety-six hours, and when the sac was opened the bowel was in a state of sphacelus. The dead intestine was slit open, and the contents above were washed out. The patient recovered with an artificial anus, which, however, gradually closed, so that all the contents of the bowel were passed in the natural way. The succeeding autumn he went nut-hunting, and ate an enormous quantity of chestnuts, which, collecting in the vicinity of the injured bowel, caused an obstruction which resulted in his death.

In reference to hernia with sphacelated bowel, Dr. Atlee referred to another case. He had been called to see Mrs. J. F., on the night of September 30, 1849; she was in an apparently moribund condition, with a cold, clammy skin, and almost pulseless, the result of strangulated femoral hernia. She had been treated for several

days for colic by her brother-in-law, a homœopath. The symptoms becoming more and more urgent from day to day, a regular physician was called in two days before Dr. Atlee saw her, and, after having tried for two hours to reduce the bowel, left the patient and did not return. When he saw her, she was in such a hopeless condition that he did not encourage an operation. But the lady insisted upon an operation. It was done by gaslight, and the whole of the extruded bowel was gangrenous. She recovered slowly, with an artificial anus, and was able to sit up on the 29th of October. The parts were treated by applications of nitrate of silver and compresses, and the opening closed by the 29th of December following. This lady is now living in Norristown, and has enjoyed excellent health ever since.

While on the subject of hernia, he would refer to another case which he saw with his brother in Lancaster. A German woman had recovered from an operation for strangulated femoral hernia. Several days after danger seemed to have passed over, she was suddenly seized with peritonitis, and died. An autopsy was made, and a lumbricoid worm was found in the peritoneal cavity, and a round opening corresponding in size to that of the worm was discovered in that portion of the intestine which had been strangulated. The worm had evidently escaped from the bowel through this opening, and was the cause of death, after the patient's life had apparently been saved by the operation.

Dr. ATKINSON referred to the case of a minister, who, for the relief of a colic, by the advice of a "wise woman," swallowed a leaden bullet. The pain having been relieved, the clergyman began to experience doubts as to the passage of the bullet, and to calculate upon the probable results of its retention. But this trouble was soon, though not very agreeably, dissipated by an assurance from the old woman that it could not fail to pass, for the same bullet had already passed in some twenty other instances.

Dr. J. H. GROVE stated that the interesting and instructive remarks with reference to cases of strangulated hernia recalled to his mind a case which came under his care, in St. Mary's Hospital, more than a year ago. The patient was a man, aged about 40, with a strangulation of a large scrotal hernia of the right side; which occurred on a Saturday evening, about 9 o'clock. He was admitted into the hospital the following afternoon. He first saw him at 5 P.M. upon that day.

The scrotum was extremely œdematous and livid. There was crackling under pressure, showing commencing decomposition. His pulse was frequent and feeble. Skin cold, with clammy perspiration; and he had stercoraceous vomiting.

He learned that taxis had been applied for several hours. He immediately proceeded to operate, and found, upon opening the sac, that along with the intestine it contained a quantity of claret-colored fluid. The stricture, which was very tight, was at the internal ring. The intestine was of a dark-purple color; its walls were œdematous and soft.

After dividing the stricture, he pulled down about half an inch of the intestine, and found the arrest of discoloration quite abrupt at the seat of stricture.

While manipulating the intestine, owing to its fragile condition it gave way at three different points, two of which were only partly through its walls, causing considerable bleeding; the other rent was entirely through, by which a red-colored fluid spurted up in a stream about twelve inches high, so that it was caught in a basin.

He placed a ligature around each separate laceration, upon the sides of the intestinal walls, cutting the ligatures short and allowing them to remain. The intestine, with about half an inch of the healthy part drawn down, was allowed to remain in the scrotum, and the incisions were closed by silver sutures.

Peritonitis supervened; a large abscess formed in the scrotum. Other unfavorable complications occurred; but, notwithstanding all, he recovered without an artificial anus; and in four weeks from the time of operation he left the hospital cured.

Professor AGNEW asked whether the bowel did not remain irreducible.

Dr. GROVE said that, when he last saw the patient, only a small portion, corresponding with the incision, remained irreducible.

Dr. ST. CLAIR ASH said that he saw the case, and considered it a very interesting one.

PATHOLOGICAL SOCIETY OF PHILADELPHIA.

THURSDAY, DECEMBER 26, 1872.

THE PRESIDENT, DR. J. H. HUTCHINSON, in the chair.

DR. J. H. CATHCART presented a specimen of *rodent cancer of the neck of the uterus*, removed from Mrs. Susan S., aged 33, married; had four children, the oldest 13 years and the youngest 3 years old. She had never had any trouble until eighteen months ago, when she began to suffer from severe pains in the back and loins. These were followed by a fetid watery discharge from the vagina, and by frequent and profuse hemorrhages. She consulted no one until about eight months ago, when she was examined by a physician, but was not treated. Dr. C. first saw her in September, and on examination found the cervix completely gone, and a large ulcer occupying the lower part of the uterus. The patient was slightly benefited by treatment which consisted in tonics and stimulants and in local applications, especially permanganate of potassa; but the doctor was obliged to desist from that part of the treatment, on account of the excessive pain caused by the introduction of the speculum. Her general health improved for some time, but frequent hemorrhages soon reduced her strength again, and she gradually sank, and died December 16.

On post-mortem examination the uterus was found in the condition presented. The entire cervix was destroyed, and the lower third of the body of the uterus. The vagina was not involved, nor was any other organ apparently affected.

Dr. JOHN ASHHURST, Jr., said, in reply to a question, that he was not disposed to regard the so-called "corroding ulcer" of the os uteri as identical in nature with the "rodent ulcer," or "Jacob's ulcer," met with in the face and other parts. The former affection, he believed, was generally acknowledged to be of an epitheliomatous character, and clinically malignant; but the structure of the "rodent ulcer" was still a matter of dispute,—Billroth, Moore, J. Collins Warren of Boston, and others, looking upon it as a true cancer, Collis of Dublin regarding it as analogous to the fibro-plastic tumor (spindle-celled sarcoma), and Paget finding in it no structures but such as are met with in ordinary chronic ulcers. While such diverse views thus prevailed as to the anatomical characteristics of the "rodent ulcer," Dr. Ashhurst thought that from its long duration, from its maintenance throughout of a strictly local character, from its not involving neighboring lymphatic glands, and from the permanent relief afforded by complete extirpation, it should be placed clinically among non-malignant affections.

DR. W. SINKLER has been elected one of the physicians to the Orthopædic Hospital and Infirmary for Diseases of the Nervous System.

MEDICAL SOCIETY OF THE COUNTY OF ALBANY.

SEMI-MONTHLY MEETING, January 8, 1873.

Reported by JAMES S. BAILEY, M D.

DR. ALBERT VAN DERVEER, President, in the chair.

THE following-named gentlemen were proposed for membership: Drs. J. Emerson Allen, Almon S. Allen, and Frank Garbutt.

Dr. J. V. P. QUACKENBUSH offered the following resolution:

"*Resolved*, That the County Medical Society shall give an entertainment to the State Medical Society at its next annual meeting, and that a committee of six be appointed to perfect the arrangements." Carried.

The President appointed as such committee Drs. Quackenbush, James P. Boyd, John Swinburne, Freeman, M. P. Hun, and Wm. H. Bailey.

On motion of Dr. Quackenbush, the President was made chairman of the committee.

Dr. CHARLES DEVOL read a paper on the medical use of alcoholic stimulants.

Dr. THOMAS BECKETT inquired what authorities claimed that alcohol was not a nutrient and assimilant, and referred to his own experience in an attack of pneumonia; he had taken many pharmaceutical remedies—carbonate of ammonia, muriate of ammonia, etc., but nothing answered the same purpose as alcoholic stimulants, and he thought they could be taken without risk. The habitual use of other stimulants has produced evil results; and the fact that alcohol was not found in nature was no objection to it, since neither is morphia nor chloral, etc., but still they were excellent remedies, and could not be dispensed with. He thought no remedy of a stimulating nature answered so well in fevers as alcohol.

Dr. DEVOL thought that either chemistry or therapeutics would answer the question, and that in Dr. Beckett's case the effect he described was due to the other remedies he had taken.

Dr. BECKETT remarked that the other stimulants gave him headache, but whiskey did not; it relieved his night-sweats, and acted as a sedative and promoter of sleep. He thought alcohol did not increase the heat of the body.

Dr. JOHN SWINBURNE inquired of Dr. Devol what proportion among foreigners who drink intoxicants die from cholera. According to his observation, nearly all classes of English, Germans, French, and Irish drink gin, beer, or porter; he was of the opinion that those who did not drink were just as likely to take cholera.

Dr. DEVOL remarked that he had never been abroad, but he believed from statistics in his possession it was estimated that in England forty gallons of beer were drunk per man, and that Paris was more intemperate in the use of wine than any other city.

Dr. SWINBURNE remarked that in Europe liquor cost more than all the other expenses of living put together; that in Germany and France they drank light wine, but did not get drunk, and he believed that but a small part of the liquor imbibed was prescribed by physicians. He thought that in our cities the larger class of drunkards was not from the lower walks of life, but that children reared in the country came here and fell into intemperance; he contended that whiskey did not shorten life, its effects were only temporary. Old age and certain temperaments required it; some bore stimulants well in fevers, and some could not take it.

Dr. Swinburne, when asked in reference to the allowance of spirits in the French army, stated that soldiers had from a pint to a quart per day.

Dr. CHAS. S. HOYT referred to an excellent paper written by Dr. Coventry at the time of the cholera in 1853, and remarked that those most liable were not the intemperate, but those who were trying to reform. Alcohol is a sedative, and is used extensively in this capacity by physicians in lunatic-asylums, in certain forms of insanity, to compose their patients. It was considered indispensable. In cases attended by rapid wasting, it was very beneficial; it increased digestion, and when nutritious diet was given it prevented the rapid decline in flesh.

Dr. BLATNER'S experience, when a student at Leipsic, while cholera was prevailing, was that red wine was used by everybody, and recommended by the professors for its nutrient and astringent effects. Speaking German fluently, he mingled freely with the inhabitants, and scarcely met a drunkard, and he believed that in Berlin the poorer classes owed their lives to the use of beer. They were paid small wages, and lived on rye bread and beer, and immorality was not observed to result from the use of it.

After a recess for refreshments, Dr. LORENZO HALE read a paper on syphilitic paraplegia caused by gummy tumor in the spinal cord.

T. H. G., colored, aged 31, died with paraplegia. He had primary syphilis five years ago, was treated several weeks until ptyalized when first attacked, and from this circumstance discharged his physician.

He first consulted Dr. Hale in July, 1870, about two years before his death. There was a large irregular white scar on the prepuce; the meatus urinarius was elongated in the direction of the frænum, and indicated the site of the primary chancre. Sarcocele had existed for some months, both testicles being enlarged. He had fever, and pains in the limbs and joints and testicles, and complained of sleeplessness.

After several weeks' use of iodide of potassium, he resumed work, and temporarily there was a general improvement in the symptoms.

During the last year of his life there was paralysis of the right leg, which came on gradually. Six months before death he had facial palsy of the left side, of short duration.

He finally became bedridden, and was so feeble that he could not turn in bed. Sensation and motion in the left leg were impaired; upon pinching the right leg, no pain was felt; he could not distinguish the difference between heat and cold when applied to the limb; his mind often wandered. The iodide of potash was neglected, and he relapsed. There was incontinence of urine and of fæces for the last two weeks; two to three pints of ammoniacal urine were drawn off twice daily. There was ascites, and finally the paraplegia became complete on both sides. There was a cold sensation upon touching the body for one week before death.

Necropsy forty-eight hours after death. Body emaciated. The abdominal cavity only was opened; it contained no fluid. Bladder empty and contracted. Kidneys presented appearance of having passed the third stage of atrophy of the waxy kidney. The second, third, and fourth lumbar vertebræ and a corresponding section of the spinal cord were removed. The cord was congested, and a gummy tumor from three-eighths to half an inch in diameter was found lying in the substance of the cord opposite the third lumbar vertebra.

Ricord is of the opinion that gummy tumor never occurs earlier than six months, and usually during the seventh year.

Hammond says intra-spinal tumors may result from the syphilitic, scrofulous, or cancerous diathesis, and relates a case of paraplegia resulting from a supposed syphilitic origin, which was cured by the use of iodide of potash.

Durkee says that they have been found in the substance of the skin, and in the subcutaneous cellular

tissue and muscles, also in the tendons, epididymis, testicle, liver, lungs, brain, bones, etc.

The microscopical appearances of gummy tumors are thus described by Lebert. A thin section of the tumor is found to consist of loose fibrous tissue, made up of pale elastic fibres, including in their interspaces a homogeneous granular substance, the elements of which are less adhesive to each other than in deposits of true tubercle. The granulated cells or corpuscles do not exceed in size .005 of an inch. They are rounded, and contain an irregularly granulated substance; some of the larger corpuscles attain the size of .0075 of an inch, have pale and irregular walls, and appear to contain a rounded nucleus.

Dr. Wm. Morgan presented a pathological specimen of cancer of the womb, taken from a case that personally he knew but little of, as he was only called to see her about one week before she died. He had gathered the following history from her and her attendants before her death:

Mrs. ——, aged 56, Irish, married thirty years, had had one child. Nine months ago her disease was pronounced to be cancer of the uterus; Dr. M. was unable to learn how much longer she had suffered from this trouble.

When taken, she was a large, fleshy woman, and seemingly enjoyed good health; but after the appearance of the disease she had gradually grown thin, without having suffered much generally, though at times she had paroxysms of severe pain. She generally slept well, and had a good appetite until about ten days before her death. Her life was active, attending daily to household duties, and some days she took long walks to visit friends.

The discharge was constant for the last nine months, and was very offensive. Ten days before death, her left leg began to swell, and became twice its usual size.

The approach of death was manifested by the twitching of the voluntary muscles of the upper extremities. The legs seemed to be paralyzed. She lost the power of speech, and became comatose four days before death.

Necropsy, twelve hours after death.

No organs were allowed to be examined beyond the pelvis. The disease was scirrhus, and implicated the whole uterus; the os, neck, and about half of the body, particularly on the left side, were entirely destroyed by ulceration. The disease had then attacked anteriorly the inner wall of the vagina, which was greatly diseased. It also extended back to the exterior walls of the rectum, but no perforation was discovered into the intestine.

The President presented for inspection a specimen of mono-bromide of camphor, which has been used in Germany for the last ten years in mania a potu. Dr. Hammond, in the *New York Medical Journal* of May last, has written upon the subject. He uses it also in convulsions and nervous diseases; the dose is from one to four grains, repeated every two or three hours if necessary.

Dr. John V. Lansing presented pathological specimens illustrating pericarditis, which were remarkable for the thickening of the pericardium, which adhered to the walls of the heart so firmly that no movement could take place. This condition was caused by inflammation.

The kidneys indicated the second stage of Bright's disease. The pericarditis was not discovered until after death. The legs were enormously swollen, and when he was first seen his urine was albuminous. The heart-sounds were indistinct and irregular; there was no valvular murmur, and the sounds were indistinct.

The dropsy was supposed to be the result of Bright's disease. There was also œdema of the lungs.

Dr. Lansing asked whether this case was complicated by disease of the kidney, or was the heart-disease the primary affection brought on by taking cold by getting wet. There was no history of rheumatism; there was exudative matter thrown out on the tubules of the kidneys.

The Society then adjourned.

OBITUARY.

THE LATE SAMUEL L. HOLLINGSWORTH, M.D.

The few lines in which we announced the death, on December 14, 1872, of this estimable physician, contained a promise, which we now fulfil, of presenting a short notice of his life and character.

Dr. Hollingsworth was born in Philadelphia, May 22, 1816. His father was a prominent merchant, and descended, in the sixth generation, from Valentine Hollingsworth, who was a member of the first Provincial Assembly in 1683. After a thorough school education, he entered the freshman class of the University of Pennsylvania; but in the junior year of his course he was sent as supercargo in one of his father's vessels to Rio Janeiro. He afterwards remained in his father's counting-house until 1839, when he commenced the study of medicine in the office of Dr. George B. Wood, and at the University, where he graduated in 1842. He subsequently served as resident physician at the Pennsylvania Hospital and at the Wills Hospital, and became one of the visiting physicians of the latter institution. At the time of his death he was one of the attending physicians of the Girard College, a post which he held with great credit for twenty-four years. During the cholera epidemic of 1849 he had charge of the City Cholera Hospital. In all of these institutions he secured the good will of their governing bodies and amassed a large amount of valuable experience. In 1854 Dr. Hollingsworth became the editor of the *Medical Examiner*, and for three years performed the duties of his office with distinguished ability. His friends regretted that this congenial field of labor should then have been closed to him by the absorption of the *Examiner* in another journal, which, like it, has passed away.

Dr. Hollingsworth's love for the study and practice of medicine was, indeed, only equalled by his fondness for literary culture. His taste led him especially to historical works, and the graver subjects of current literature, as they are presented in the leading reviews and standard works of Great Britain. His mind was stored with the fruits of these excursions beyond professional fields, and his conversation never failed to give evidence of his intellectual riches by the seriousness of its tone as well as by the fulness and variety of his information. He was therefore listened to with attention, and his judgment was often appealed to in questions of historical fact and of literary opinion.

His views on all subjects were the more valued because they were felt to be sincere. Indeed, his love of truth for its own sake was perfect. For falsehood in every shape he had an instinctive hatred; he neither spoke nor acted it, nor could he tolerate in others any deviation from the simple and straightforward path, holding that no motive of self-interest can palliate a moral wrong. Hence, as became such a man, his conversation and actions were always pure, and his manners as simple and natural as they were courteous and kind.

Dr. Hollingsworth was one of the many men of merit who prefer the peaceful paths of life to a struggle for prominence in the world's thoroughfare. Neither professional nor any other form of public preferment tempted him away from his useful and happy, but un-

ostentatious, career. He found abundant satisfaction of his moral cravings in the domestic circle, in the study and practice of medicine, and in social intercourse with his professional brethren. He will long be remembered by them as an accomplished scholar and physician, a genial companion, and an upright man.

REVIEWS AND BOOK NOTICES.

CLINICAL LECTURES ON DISEASES PECULIAR TO WOMEN. By LOMBE ATTHILL, M.D. Univ. Dubl., etc. Second Edition, Revised and Enlarged, with Six Lithographic Plates and Woodcut Illustrations. Crown 8vo, pp. 241. Philadelphia, Lindsay & Blakiston, 1873.

OBSTETRIC APHORISMS: FOR THE USE OF STUDENTS COMMENCING MIDWIFERY PRACTICE. By JOSEPH GRIFFITHS SWAYNE, M.D., etc. Second American, from the Fifth Revised English Edition, with Additions. By EDWARD R. HUTCHINS, M.D. 12mo, pp. 189. Philadelphia, Henry C. Lea, 1873.

FŒTICIDE, OR CRIMINAL ABORTION. By HUGH L. HODGE, M.D. Fourth Edition. 18mo, pp. 55. Philadelphia, Lindsay & Blakiston, 1872.

THE USE OF THE SETON IN THE TREATMENT OF SOME CASES OF CHRONIC AFFECTIONS OF THE WOMB. By ELY VAN DE WARKER, M.D., etc. Reprinted from the *Journal of Obstetrics*. 8vo, pp. 16.

Dr. Atthill's work appears to be an exhibit of the experience and practice of the Adelaide Hospital, Dublin, and of the results of his own observations. It does not claim much, but its merits are very considerable. While we do not agree with all the views of its author, and are especially inclined to deprecate his advocacy of mechanical treatment by pessaries, we think no one will take up his book without interest and profit.

The second book in the above list is one, in our opinion, admirably adapted to be of service to the class of readers for whom it is designed. Unfortunately, recent graduates will be too apt to pass it by for more pretentious volumes.

Dr. Hodge's introductory lecture on Fœticide, first delivered in 1839, and again in 1854, has probably done much, in its former larger shape, towards the dissemination of just views of that grievous crime against society. We are glad to see a reissue of it; but we fear its influence will be lessened by reason of its insignificant appearance.

Dr. Van de Warker's idea, which, however, is not wholly new, is to establish, in certain cases of chronic hypertrophy of the uterus, drainage by means of one or more silk threads passed through the tissues of the os. The obstinacy of many of these cases would make the discovery of an effectual means of treatment a great boon to both practitioner and patient, and the plan in question seems to us to merit trial.

OUTLINES OF SURGERY AND SURGICAL PATHOLOGY, INCLUDING THE DIAGNOSIS AND TREATMENT OF OBSCURE AND URGENT CASES, AND THE SURGICAL ANATOMY OF SOME IMPORTANT STRUCTURES AND REGIONS. By F. LE GROS CLARK, F.R.S., Senior Surgeon to St. Thomas's Hospital. Second Edition, Revised and Expanded by the Author, assisted by W. W. WAGSTAFFE, F.R.C.S., etc.

This book, which is as concise as it could well be made, is as difficult to review as it would be to read continuously. It is intended for students of surgery as a sort of synoptical guide, and will doubtless be found of great use for this purpose. A careful examination of it enables us to endorse it as sound in every respect, and eminently worthy of recommendation to their classes by teachers of this branch of medical science.

BOOKS AND PAMPHLETS RECEIVED.

A Handbook of Therapeutics. By Sidney Ringer, M.D., etc. Third Edition. 8vo, pp. 576. New York, William Wood & Co., 1872.

Transactions of the Medical Society of the State of New York for 1870 and 1871. 2 vols. 8vo, pp. 429 and 490.

The Post-Office Directory of Chemists and Druggists; Including Chemical Manufacturers, Wholesale Druggists, Drysalters, and Patent Medicine Vendors, of England, Scotland, and Wales. To which is appended the Chemical Manufacturers and Wholesale and Retail Druggists in the Principal Towns in Ireland. Second Edition. Large 8vo, pp. 546. London, Kelly & Co., 1872.

The Nineteenth Report upon the Registration of Births, Marriages, and Deaths in the State of Rhode Island, for the Year ending December 31, 1871. Prepared under the direction of Joshua M. Addeman, Secretary of State, by Edward T. Caswell, M.D. 8vo, pp. 116. Providence, 1872.

Transactions of the Wisconsin State Medical Society for the Year 1872. Vol. vi. 8vo, pp. 169. Milwaukee, 1872.

GLEANINGS FROM OUR EXCHANGES.

STRICKER AND COHNHEIM (*Berliner Klin. Wochenschr.*, No. 41).—On the 15th of August, 1872, during the session of the Association of Naturalists and Physicians in Leipsic, Prof. Stricker made the following remarks in reply to the repeated attacks of Cohnheim:

Two of his pupils, after subjecting cartilage to severe irritation, injected cinnabar into the blood, and then discovered the foreign matter in the inflammatory points. In order to prove that such was the truth, Prof. Stricker presented a preparation in which particles of cinnabar were seen in the tissue of cartilage. Prof. S. requested the president to appoint several skilful microscopists to examine the specimen, and to testify as to the reliability of his statements.

Profs. Biesiadecki, Ackermann, Rollett, and Dr. Steudener were appointed, and they confirmed the statement already alluded to. Prof. Stricker then said that by destroying the ganglion of Gasser he had produced an inflammation of the cornea on the corresponding side. This could not have been caused by the entrance of dust into the eye, on account of the anæsthesia and patulency of the eyelids; for the other eye of the same animal was also exposed to the full effects of dust, by the destruction of its inferior nictitating membrane, but was not inflamed. The neuritis slowly passed away, and small nodules were formed, to which passed, from the edge of the cornea, small avenues formed of cells containing pigment.

Such a condition is important, because the pigment, which can come only from the eye, in this case, is found in cells which are not wandering white blood-corpuscles.

Hence the conclusion of Cohnheim that cells containing cinnabar, which are found in the inflamed cornea after this coloring-matter has been injected into the blood, are white blood-corpuscles, is incorrect, and consequently his theory is deprived of one of its chief supports.

Prof. Stricker, in conclusion, produced his specimen of traumatic keratitis, and requested Prof. Cohnheim to look at it. The latter gentleman said that he had had no intention of entering into the discussion, since a public assembly was no place to discuss the merits of a microscopic preparation. The question concerning the occurrence of cinnabar in inflamed cartilage possesses but little weight in the present discussion. For, since no one doubts that pus-corpuscles do escape in inflammatory processes, it is quite fair to presume that particles of cinnabar may be also conveyed to any part of the body affected by inflammation.

So far as the preparation from the irritated cornea is concerned, Prof. Cohnheim declined to consider it, or even to look at it. If the preparation were made according to this method, without doubt the corneal corpuscles could be seen intact. He could only advise Prof. Stricker to work in the future with more care and cleanliness, and to institute observations according to the prescribed method. In that event he would obtain the same results as he (Cohnheim) had. The present negative discovery proved nothing, and he was unwilling to relinquish his views.

Prof. Stricker said that, since Prof. Cohnheim had not seen the specimen of traumatic keratitis, all further debate was impossible. The number of adherents of a theory by no means proved its correctness.

It is usual to imitate the methods of those who go further in any investigation. He had discovered new methods; and the burden of proof now lies on the side of Cohnheim, who must imitate, and then admit or deny the truths he (Stricker) had declared.

Prof. Rindfleisch concluded the discussion by stating that, after repeated examinations of the specimen of intense keratitis, he had been able to discover the *stellate corneal bodies* in it. Their outlines, however, were quite indistinct, and they were very pale,—changes which may be due to saturation by the fluid in which they were placed. The *numerous apparently spindle-shaped cells*, Rindfleisch declared to be colorless blood-corpuscles which are situated in the finest vessels of the cornea, and which distend these vessels at the affected joints. The circumstance that these nutrient vessels of the cornea run from the spaces in the cornea mostly in the same direction, gives the impression that the apparently spindle-shaped cells which lie in them are also arranged in the same direction. Their number, however, four times as numerous as the true cells of cornea, forbids their being mistaken for altered corneal cells.

Malaria as a Cause of Renal Disease (*Am. Journal of the Med. Sciences*, Jan. 1873).—Dr. S. C. Busey, of Washington, D. C., after reporting three cases of renal dropsy (one of amyloid degeneration, one of desquamative nephritis, and one of hyperæmia of the kidneys) in children aged respectively 15, 9, and 4 years, makes the following remarks:

"These three cases present, in common, five phenomena: dropsical effusion, emaciation, marked anæmia, albuminuria, and lessened density of the urine, which point directly to disease of the kidneys. But was the renal affection primary or secondary? The determination of this question involves, mainly, the consideration of the cause. In Cases II. and III. it is manifest that the malarial cachexia was primary, and, though not absolutely demonstrated in the case of amyloid degeneration, it is fairly inferred from the history of the patient. There is nothing new in this sequence of disorders. Parkes affirms, from personal experience, 'that chronic Bright's disease is a consequence of ague.' Niemeyer says the 'poison of malaria' may cause Bright's disease. H. C. Wood, in a recent essay, published in this journal, enumerates malaria among the causes of albuminuria. Johnson maintains that the poison of fevers is eliminated through the kidneys, and, though not distinctly classing malaria among the causes, dwells with great pertinacity upon the casual relation of dyscrasiæ generally to Bright's disease. Stewart enumerates ague among the causes. Dr. Woodward, of the army, in his work on camp diseases, at page 185, in discussing 'chronic malarial poisoning,' says, 'Disorder of the kidneys frequently complicates the condition under consideration. Scanty, more or less albuminous urine is often observed, and these cases which occasionally perish with the symptoms of acute uræmic toxæmia not unfrequently terminate in chronic Bright's disease, with confirmed albuminuria, œdema, or general anasarca, and the whole train of symptoms of that disorder.' It is an accepted doctrine that any toxæmic condition of the blood, wherein the poisonous agent may be eliminated through the renal secretion, may produce some one of the forms of Bright's disease. This is demonstrated in cholera, scarlatina, rheumatism, erysipelas, measles, diphtheria, typhoid fever, pyæmia, syphilis, gout, and in exhaustive suppurative and carious affections. In all the dyscrasiæ the kidney complication is secondary, and perhaps no one of the cachexiæ is more marked in its pathognomonic characteristics or more fruitful in sequences than the malarial, none more destructive of the healthy constitution and nutritive qualities of the blood, and none more enervating. Besides the general phenomena which so manifestly distinguish the malarial cachexy, and which so markedly exhibit the effects of deficient hæmatosis, there are certain direct and immediate alterations produced in the character of the urinary secretion. Parkes has shown that the moment a paroxysm of malarial fever begins, the excretion of urea increases, such increase continuing during the algid and hot stages, diminishing during the sweating, and falling below the healthy standard during the intermittence; also that the uric acid is greatly increased during the fit. Ringer asserts that the quantity of urea corresponds to the degree of temperature; also that the chloride of sodium is greatly increased during the hot and cold stages, and that albumen is found, in a limited proportion of cases, during the fit, with blood and renal cylinders. McClean says, 'The blood is changed from the beginning of the attack, and, probably, for some time. The red globules and fibrin are diminished. The coagulum is larger and more flabby than that of healthy blood, much darker in color.' Aitken insists that 'an altered, defective, or contaminated state of the blood is the source of the morbid phenomena which follow.' Among the numerous causes of desquamative nephritis there is none more frequent than cold. Cold cannot act by lessening the temperature of the kidneys. The renal affection is secondary to the arrest of the cutaneous transudation and the determination of the blood to the internal organs. In the algid stage of intermittent fevers these conditions are superadded to the blood infections, and not only is augmented duty imposed upon the kidneys, because of the arrest of the functions of the skin, but their functions are impaired by the obstructive hyperæmia resulting from the interruption of the cutaneous circulation.

"Rokitansky, Walshe, Watson, Johnson, Aitken, and many others maintain that the various forms of Bright's disease find their cause in the quality of the blood sent to the kidneys, and that the *materies morbi* seeks its discharge through the secretory function of the kidneys.

"No age is exempt from nephritis. Rayer observed many cases from six months to one year. Noel reports a case eighteen months old; and Grisolle one a few weeks old."

Enucleation of Uterine Fibroids (*Am. Journal of Obstetrics*, Nov. 1872).—Dr. Thomas exhibited to the Obstetrical Society of New York, Oct. 2, 1872, a mass the size of a cocoanut, consisting of three fibroids which he had recently removed by enucleation. The woman, who was a patient of Dr. H. Moeller, had suffered for some months from excessive menorrhagia. When seen by Dr. Thomas, the uterus was found to be as large as at the fifth month of gestation; the cervix was found well dilated, and a large fibroid presenting, which, on examination, proved to be sessile, and attached posteriorly. The patient lying upon her back upon a table, Dr. Thomas proceeded to enucleate by cutting through the capsule of the tumor with scissors, and then insinuating a grooved steel sound under the capsule, which he separated as far as possible from its attachments. Traction was then resorted to, combined with powerful expression from above, which resulted in the extrusion of a large mass in about forty minutes; another mass was felt above the one extracted, which was in like manner removed; traction then being made upon the capsule, it came away, having attached to it a still smaller tumor. There was very little hemorrhage. Opiates were given, and intra-uterine injections of carbolic acid were daily used. The patient did well for four weeks, though she now has a mild attack of phlegmasia dolens, from which she has suffered once before as a sequel to parturition. This is the sixth case in which Dr. Thomas has resorted to enucleation, in all of which the recovery has been perfect. He has, however, lost two cases in the preparatory treatment by sponge-tents. Dr. Thomas considers the operation in its results more formidable than ovariotomy.

Dr. Peaslee agreed with Dr. Thomas in the operation being more dangerous than ovariotomy, though it looks so simple. It is always dangerous to operate while the tumor is in the uterus, though where danger exists from menorrhagia the operation is perfectly justifiable.

Dr. Sims thought the removal would be facilitated by the patient being in the left lateral semi-prone position, and instanced a case where he had effected the removal of a tumor in twelve minutes.

Dr. Thomas, in reply, said that he had removed tumors in less time than that mentioned by Dr. Sims, and he considers the dorsal position better, as expression can be so efficiently brought to bear.

Chloroform as a Solvent for and Means of Separating Poisonous Vegetable Substances in Forensic Investigations.—The *Journal of Applied Chemistry* for December, 1872, says, "Nowak has instituted a series of experiments which prove that chloroform quickly and perfectly extracts the following long list of vegetable substances from alkaline solutions, viz.: Strychnia, quinia, quinidia, cinchonia, caffeina, theobromina, emetia, atropia, hyoscyamia, aconitina, veratria, physostigmia, narcotina, codeia, thebaina, nicotina, and conia. It dissolves brucia, colchicia, and papaverina more slowly. Sabadillia is only taken up by it when warm, while narceia is taken up from alkaline solutions in small quantities only. Picrotoxin is acted upon by chloroform more readily from acid than alkaline solutions. Morphia and solania do not dissolve in chloroform, either from acid or alkaline solutions.

"Further experiments also show that all those substances which are taken up by chloroform from aqueous alkaline solutions are again given up by it on shaking repeatedly with acidulated water, while fatty and other foreign substances mixed with them remain in the chloroform. A systematic course of search for poisonous vegetable substances, founded upon the above facts, was instituted, and its practicability tested by actual experiments as follows: A weighed quantity of different poisons was mixed with pieces of flesh selected for the purpose, and then tested for. The results obtained showed that in many cases the whole quantity of the poison mixed with the flesh was recovered, and in most cases the greater part was found. The results gave general satisfaction, especially on account of the great purity of the alkaloids obtained from the chloroform, so that the reactions for identifying them could be made at once."

Limits of Normal Bronchial Breathing (*Berliner Klinische Wochenschrift*, No. 41, 1872).—According to a series of investigations made upon 216 persons of various age, sex, and avocation, by Lippe, the assistant in the clinic at Dorpat, the following laws may be laid down:

1. Bronchial breathing is always to be heard in the region of the seventh cervical vertebra (in some rare cases it is heard only here), but usually it is heard more or less extensively below this point.

2. Below this point it is heard in the rarest cases only, on the right side of the thorax (four times in 213 cases). The rule is to hear it on both sides.

3. The extent of bronchial breathing stands in an inverse ratio to the difference between the circumference of the chest and half the length of the body. In the first four decades of life, a gradual increase of this difference occurs, and on the other side a gradual decrease of the bronchial breathing. In the later years of life the extent of the latter increases, while at the same time the difference diminishes. With the sixtieth year of life the bronchial breathing has again reached the same limit as in the first decade of life.

Cholera.—According to the *Wiener Mediz. Presse* of Nov. 3, 1872, this unwelcome visitor had made its appearance in Hungary and Eastern Austria, moving westward. In Ofen, Hungary, between the 13th and 25th of October, 126 cases of cholera had appeared, of which 29 proved fatal. In the garrison of the same place there were 29 cases, of which 5 died. In Pesth, 4 cases had appeared at the time the communication was made. In Lemberg, near Vienna, 140 cases occurred between September 23 and October 23, 1872, of which 40 died. The Emperor of Austria has caused every precaution to be taken in order to prevent its coming to Vienna.

Double Amputation by Pirogoff's Method.—Dr. J. Lizars Lizars, of Toronto, reports in the *Canada Lancet* for January, 1873, a case of railroad injury, in which he removed both feet of a French Canadian, aged 28 years, by the above-mentioned procedure. One operation was performed on October 24, and the other on November 3, 1872. On the 4th of December the patient was doing well.

Dr. L. justly remarks on the propriety of dividing the os calcis, in this operation, in a direction downwards and forwards, instead of directly downwards; the former plan bringing the subsequent pressure more on the thick skin of the heel.

"Open-Air" Treatment of Hooping-Cough.—In the *Glasgow Medical Journal*, Dr. McLean strongly advocates this plan of treatment, which consists in keeping the little patient as much as possible out-of-doors in the open air. He does not consider this plan of treatment as a specific in every case of hooping-cough; but it is one which, in the hands of a judicious physician, can be made of immense utility, and even in certain complications can be adopted with safety.

MISCELLANY.

Eating Dirt.—It is a common opinion that even in the most civilized communities it is not easy to avoid one's peck of dirt; and some individuals manifest quite a peculiar talent for it, and go through the operation with a readiness and grace which seem to imply a suppressed inclination for the practice. Dr. Frank Galt, of Iquitos, Peru, describes quite a devouring passion for it to prevail among the mestizoes, or half-breeds, of the Upper Amazon. His account is very interesting. Dirt-eating becomes an irresistible passion.

"Even strangers, English, or the white Peruvian, who have married with the mestizo, and have had children by them, find its presence among the little ones the plague of their life; and the accounts one hears about the tyranny of this habit of dirt-eating on the victims of it would seem almost fabulous, were there not evidences all around one to give sanction to them. Children commence the habit from the time they are four years old, or less, and frequently die from the results in two or three years. In other cases, they grow to manhood or womanhood with the 'appetite growing by what it feeds on,' and I have seen here myself, in the case of a mestizo soldier, who was dying from the dysentery which generally, sooner or later, supervenes on this habit, the poor creature, half an hour before his death, detected with a lump of clay stuffed in his sunken cheeks, which he had dragged from the wall near where he was almost breathing his last. Officers here who have the Indian or half-breed children as servants in their employ sometimes have to use wire masks to keep them from putting the clay to their mouths; and women, as they lie in bed sleepless and restless, will pull out pieces of mud from the adjoining walls of their room to gratify their strange appetite, or will soothe a squalling brat by tempting it with a lump of the same material. If persisted in, the effects are surely fatal, at varying terms of years, some living tolerably to middle age, and then dying with dysentery, or from that disease at an earlier period. In the children dropsy is usually the most prominent apparent cause of decline and death."

A project is on foot to resume the publication of a Hospital Gazette in Dublin, containing only original scientific matter. It would be published twice a month, would consist of sixteen pages only, and would be issued at an annual subscription of half a guinea.

Mr. Holmes Coote.—The *British Medical Journal* of Dec. 28 says, "We have to chronicle the death of Mr. Holmes Coote, Senior Surgeon and Lecturer on Surgery of St. Bartholomew's Hospital, at about the age of fifty-six. It is seldom that so sad a fate has to be recorded of a man occupying an eminent position in a learned profession. While actually surgeon and lecturer on surgery at St. Bartholomew's Hospital, this unhappy gentleman breathed his last this week in a public lunatic-asylum, and has left his family destitute. Incipient brain-disease, brought on, probably, by the pressure of anxieties and misfortunes, had interfered with Mr. Coote's professional pursuits, although, until the last few months, not disabling him from attending to his hospital work. The kindness of his colleagues in performing his duties has enabled him to retain lately the title and emoluments of an office of which he at last became unequal to the duties. Mr. Coote began life under circumstances of great promise. A skilful anatomist and an active teacher, a surgeon of some fertility and resource, not unskilled in the use of the pen or disinclined to use it, well placed at one of our great hospital schools, his friends anticipated for him a brilliant career. Mr. Coote filled with credit many offices of importance. Besides taking a large and useful share in educating successive annual generations of students, he served in the Crimean hospitals with honor, and has since held office as one of the Commissioners under the Contagious Diseases Acts, and as an Examiner in Surgery of the Royal College of Surgeons. His contributions to Holmes's 'System of Surgery' were respectable, and his earlier anatomical writings (one of which received the College Triennial Prize in 1845) were of some repute. A career so well begun was sadly and even tragically ended. His friends and pupils, remembering his many good qualities, will not, it may be hoped, be slow to render kindly and seasonable aid to his family."

Curious Freak of Nature.—The description of the hairy family at Mandalay, whom the king will not permit to leave his dominions, with pleasant allusions to Darwin, has lately been going the rounds of the medical press. A correspondent of the *London Times* furnishes some additional information. He writes, "When I was at Mandalay in '59, I saw the same woman and three of her children. The eldest and youngest were hairy, like their mother, while the second, like his father, presented no such peculiarity. The husband was a man who, report said, had been induced to wed this woman to become possessed of the marriage-portion which the King of Burmah had promised to bestow upon her on her bridal day. The bridegroom was a plucky fellow, at any rate, though his motives may have been somewhat mercenary. The hairy woman had a pleasant, intelligent face,—there was nothing whatever repulsive in it. The hair on the face and breast was several inches long; on the forehead it was parted in the middle and blended with that of her head. Of a light brown color on her cheeks, it paled gradually towards the bridge of her nose and the centre of her lips, chin, and neck."

Social Evil Hospital, St. Louis, Mo.—The site for this new hospital, designed for the reception of fallen women, has been selected by the board of health of St. Louis. The inauguration of this institution is the climax of a system that some two years ago received the sanction of the authorities there, and which, since then, has been carried on with all the vigor and inflexibility of other established laws,—the registration of abandoned women, their examination by a staff of

physicians, and their payment of weekly and monthly dues. The regular weekly payment of a dollar and a half by each courtesan, and fourteen dollars monthly from each keeper of a house of ill-fame, has resulted in the accumulation of many thousand dollars, which is now being appropriated, in accordance with the requirements of the law, for the treatment of these women.

DRESSER'S ENGLISH IN INDIA.—The *British Medical Journal* says, "Notwithstanding the improvement in the education of native medical pupils, it appears that dresser's English in India is still something of the same kind of dialect as pigeon-English in China. The *Madras Medical Journal* prints the following specimen of a medical certificate given by a hospital assistant to a patient who had his teeth loosened by a blow on the mouth:

"'I do hereby certify that the Village Moonsiff —— of —— aged about 45 was found on my examination suffering from shaking of 2 front upper teeth, and 4 front lower teeth and besides several other teeth also in a slight shaking state. I consider that the shaking appear to have been caused by another individual, or by fall, or by natural and previous administration of cruel mercury. I am of opinion that the hurt is not a mortal.

"'(Signed) ———, *2nd Class Hospl. Asst.*'"

A MYSTERIOUS CASE.—The following item appeared in a recent issue of the *New York Tribune:*

"Coroner Keenan was asked yesterday afternoon, by Dr. Charles P. Russell, Registrar of the Bureau of Vital Statistics, to hold an inquest on the body of Elizabeth Taylor Church, wife of Dr. E. P. Church, of No. 629 Ninth Avenue, who died January 5, 'from abscess of the right lung, caused by an injury inflicted with a wire by the deceased during an attempt to produce an abortion upon herself.' Dr. Russell stated that an autopsy by Prof. T. Gaillard Thomas, of the Twenty-third Street Medical College, and Dr. Charles S. Ward, of No. 61 Macdougal Street, had 'revealed the presence of a wire about twenty inches long,' which had passed upward through the peritoneal cavity and penetrated the lung."

DR. B. HOWARD says, in the *New York Medical Journal* for December, 1872, that within six years from its formation the Humane Society of Amsterdam reported the recovery of two hundred persons. Mr. Alexander Johnson, in a report to the Humane Society of London, states that from 1774 to 1787, a period of thirteen years, eight hundred and ninety-seven instances of resuscitation occurred in London alone. According to the report of Monsieur Pia, the superintendent of the Establishment for the Recovery of the Drowned in Paris, during the sixteen years subsequent to 1772 eight hundred and thirteen persons, apparently dead from submersion, were completely restored; one hundred and twenty cases only having been treated unsuccessfully.

ON A RESURRECTIONIST.—The following lines have their own historical interest, as relating to a past state of things which concerned anatomical students, and are worthy of a place in our columns, if only for their epigrammatic wit and finish. They appear in *Blackwood's Magazine* for November, 1872:

"Here lies an honest man, my brothers,
Who raised himself by raising others.
Anxious his friends from soil to save,
His converse still was with the grave.
To rescue from the tomb his mission,
He took men off to the physician;
And strove that all, whom death releases,
Should rest, if not in peace, in pieces.
So here he waits his resurrection,
In hopes his life may bear dissection."

THE cause of the ex-Emperor Napoleon's death was stated in one of the daily papers to have been embolism, "caused by the intercallations of the electric currents in the operation of lithotrity."

THE many friends of Dr. Wilmer Worthington, of West Chester, will be glad to know that he is at present much better, and that hopes are entertained of his recovery.

PROF. R. VON JAGER has received the Order of the Crown, of the third class (Prussian), and the Order of St. Michael, of the first class (Bavarian).

MORTALITY OF PHILADELPHIA.—The interments reported at the Health Office for the week ending Jan. 18, 1873, were 325; 179 adults, and 146 minors. 6 were of bodies brought from the country; making the mortality of the city 319. Among the causes of death were:

Consumption of the Lungs	41
Other Diseases of the Respiratory Organs	65
Diseases of the Circulatory Apparatus	18
Diseases of the Brain and Nervous System	50
Diseases of the Digestive Apparatus	17
Zymotic Diseases (one from Smallpox)	29
Typhoid Fever	8
Casualties	3
Cancer	4
Gangrene	4
Suicide	1
Debility (including "Inanition" and "Marasmus")	31
Still-born	16
Old Age	11

The following may be specially noted: *Caries of the liver*, 1; dyspepsia, 1; rupture of the heart, 1; rupture of the uterus, 1.

(The interments reported for the week ending Jan. 20, 1872, were 503.)

THE meteorological record kept at the Pennsylvania Hospital was as follows:

	THERMOMETER.		BAROMETER.
	Max.	Min.	(2 P.M.)
Jan. 12	28.0°	17.0°	30.62 in.
" 13	42.5	29.0	30.34 in.
" 14	45.5	34.0	30.34 in.
" 15	35.0	31.0	30.65 in. (Rain.)
" 16	59.0	37.0	30.15 in. (Rain.)
" 17	54.0	33.0	30.01 in.
" 18	34.0	31.0	29.92 in. (Rain.)

SATURDAY, FEBRUARY 1, 1873.

ORIGINAL LECTURES.

LECTURES

ON THE SURGERY OF THE NARES, LARYNX, AND TRACHEA.

BEING THE MÜTTER LECTURES FOR 1872.

Delivered before the College of Physicians of Philadelphia,

BY J. SOLIS COHEN, M.D.

Reported by R. M. BERTOLET, M.D.

LECTURE I.

(Continued from page 259.)

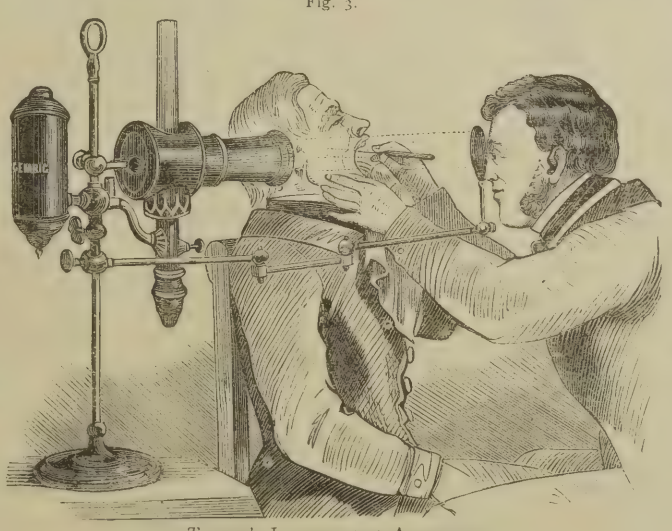
ILLUMINATION BY SUNLIGHT.

DIRECT sunlight is available only during a certain portion of the day. When this direct illumination is impracticable, we may reflect the light to a convenient point by means of a tilted piece of looking-glass; or we may concentrate the diffused daylight in the apartment upon a concave mirror, and reflect it thence into the mouth of the patient.

ARTIFICIAL ILLUMINATION.

This may be direct or reflected, and the rays of illumination may be concentrated by means of lenses. Reflected light is much more easily managed. The reflector is often used attached to the head of the examiner. Many — and the lecturer among them — prefer to use an apparatus in which the reflector is permanently attached to the lamp; and of all those in use — many of which were exhibited and explained — he prefers the illuminator of Tobold (Fig. 3).

Fig. 3.



TOBOLD'S ILLUMINATING APPARATUS.

The source of illumination is a coal-oil lamp, or an argand gas-burner, capable of being set at any elevation upon the support, and of being changed at will. This is surrounded by a tube containing a series of three condensing lenses for increasing the light. The reflector is attached to the illuminating apparatus by a jointed, movable arm. In using this apparatus, the flame should be placed about on a level with the patient's mouth.

This apparatus has been rendered more convenient for constant use, by taking the support from the floor and suspending the reflector above the lenses. Such an arrangement keeps the supporting arm out of the way of the left hand, when operating upon the larynx. The source of light is an argand gas-burner, fed from a convenient bracket or pendant, by means of flexible tubing. This adaptation of the Tobold lamp (Fig. 4) leaves but little to be desired in the way of illumination, and has gradually come into general use in this country.

In employing artificial light, the room is darkened somewhat, so as to exclude any excess of daylight which would interfere with the artificial illumination.

AUTO-LARYNGOSCOPY.

This is the term used to designate one's examination of his own larynx, which is done by performing the operation before a toilet-glass or hand-mirror. It is especially valuable in familiarizing one's self with the laryngo-pharyngeal image, and in studying the various physiological phenomena of respiration, vocalization, etc.

DEMONSTRO-LARYNGOSCOPY.

This term is used to designate the demonstration of the larynx to others, which is best done by placing a hand-mirror in the grasp of the patient, or a small mirror obliquely in front of his mouth.

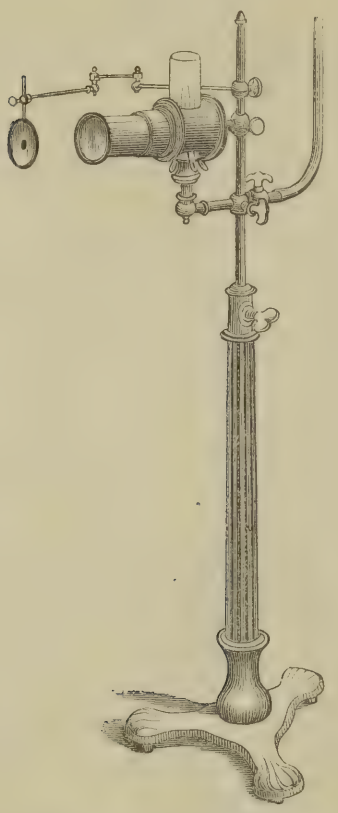
THE STRUCTURES THUS SUBJECTED TO OBSERVATION.

The structures most prominent in the mirror are, normally, the epiglottis, the cartilages of Santorini, and the vocal cords: they are readily recognized; but many other important parts are reflected, which are not easily located until some familiarity has been acquired in laryngoscopic examination. It is the same as in the cultivation of observation under the microscope; many things are recognized, as we grow accustomed to the use of the microscope, which we did not detect before, although they were in the field all the time.

The structures thus exposed to inspection are, from before backwards: the posterior portion of the base of the tongue; the posterior surfaces of the anterior palatine arches, and their attachments to the sides of the base of the tongue; the lateral ligaments connecting the tongue with the hyoid bone; the ligaments connecting the tongue with the epiglottis, and the lingual sinuses between the middle glosso-epiglottic ligament and the two lateral ligaments or folds; the tonsil glands; the posterior palatine arches, as they run downwards and backwards to be lost in the sides of the pharynx; the ligaments

connecting the epiglottis and pharynx; the lateral ligaments connecting the epiglottis with the hyoid bone; the epiglottis itself, its anterior or lingual surface, its upper and lateral borders, and its posterior or laryngeal surface; the ligamentous folds of mucous membrane connecting the sides of the epiglottis with the arytenoid cartilages, and forming the upper portion of the quadrangular membrane of the larynx; the arytenoid cartilages, with the cartilages of Santorini at their apices, imbedded in

Fig. 4.



Tobold's Illuminating Apparatus, supported from Floor, fed with Gas. Reflector attached above, instead of below.

sub-mucous cellular tissue; the base of the cuneiform or Wrisberg cartilages, enclosed within the ary-epiglottic folds, a few lines from their arytenoidal extremities; the fold of mucous membrane between the arytenoid cartilages; the pear-shaped sinuses just outside of the laryngeal cavity, comprising the space between the exterior surface of the quadrangular membrane of the larynx and the inner surface of the thyroid cartilage; the posterior wall of the pharynx, as far down as the position of the cricoid cartilage, where the entrance into the œsophagus appears as a narrow groove communicating with the pear-shaped or pyramidal sinuses; the upper cavity of the larynx and its component structures; the vocal cords, and above them the ventricles of Morgagni; the ventricular bands, known as false vocal cords, above the ventricles, and formed on each side by a duplicature of the laryngeal lining membrane; a portion of the lower cavity of the larynx, and the internal face of the anterior portion of the thyroid cartilage, cricothyroid membrane, and cricoid cartilage; the anterior portion of the trachea, to a greater or less extent, and, under very favorable circumstances, clear down to the bifurcation of the tube; and, in a few cases, more or less of the continuity of the right bronchus; under peculiar circumstances, more or less of the posterior wall of the trachea.

Such are the structures which the laryngoscope enables us to examine in the living subject. It is impossible to bring all the tissues enumerated into one and the same view; but by altering the direction of the mirror, a little forward or backward, to one side or the other, the light can be reflected upon all these structures in succession, and their condition observed. In moving the mirror, or giving it a further inclination to one side or the other, we must avoid any tremulousness. It is this constant hitting of the parts that provokes spasmodic contraction. A decided, though gentle, pressure upon the parts is borne much better. It is for this reason that the recommendation has already been made to rest the lower edge of the mirror upon the posterior wall of the pharynx. In this way we avoid titillation of the parts, which is so apt to ensue when we follow the rules laid down by several laryngoscopists, to avoid touching the soft palate, and particularly the pharynx. The only part to avoid is the base of the tongue, contact with which induces retching.

RHINOSCOPY.

In the rhinoscopic examination, we turn the reflecting surface of the mouth-mirror upwards, so as to illuminate the upper portion of the pharynx and the posterior outlet of the nasal passages. The same apparatus and sources of illumination that are employed for laryngeal examinations are also applicable in rhinoscopy; but the tongue, instead of being protruded, must be held down, in most cases, by some suitable tongue-depressor. The patient must be instructed how to regulate his respirations by breathing through his nostrils. The rhinoscopic mirror must generally be of a smaller size than that employed for laryngoscopy. It is generally attached at right angles to the handle; but the lecturer prefers to use the ordinary small laryngoscopic mirror. Often there is more or less approximation of the soft palate to the posterior wall of the pharynx, and the view is thus limited or rendered impossible. To increase the naso-pharyngeal space, variously-shaped tractors, hooks, and snares have been resorted to; but their presence usually gives rise to so much irritation that the soft palate is spasmodically drawn up against the pharynx. Their use has generally been abandoned, except in rare cases. In the performance of operations, the palate can sometimes be held up by tapes carried through the nasal passages by Bellocq's canula and tied over the upper lip; but even this manœuvre cannot be long tolerated.

ORIGINAL COMMUNICATIONS.

THE LOCAL TREATMENT OF CANCER OF THE FEMALE GENITALS—CASE OF PRIMARY CANCER OF THE VAGINA.

BY JOHN S. PARRY, M.D.,

Attending Accoucheur to the Philadelphia Hospital, etc.

Remarks made before the Pathological Society of Philadelphia, November 14, 1872.

AT the last meeting of the Society I presented a specimen of cauliflower cancer, which had been removed from the os uteri of a mulatto woman thirty years old. At the same time attention was called to the fact that the operation for removal had been postponed for three months on account of the great prostration of the patient, and that Dr. J. H. Cathcart, who had charge of the woman, and with whom she was seen in consultation, had scraped away almost the whole of the morbid growth, an operation which was followed by the most marked improvement in the condition of the patient. For eleven weeks before this she had been confined to her bed, having become greatly emaciated and profoundly prostrated by the profuse hemorrhages from which she suffered. The growth at that time filled the upper part of the vagina, pressed back upon the rectum, nearly obliterating the calibre of that canal, and extended downward almost to the vulva.

After the removal of all of the morbid tissue which Dr. Cathcart could tear away with a blunt instrument, the flow of blood entirely ceased, her bowels, which had before been constipated, became regular, her appetite improved, and she rapidly gained both flesh and strength, so that three months later she would hardly have been recognized as the same person, so great was the improvement. Indeed, to all appearances she was in perfect health. She pursued her ordinary avocations, went about the city as she pleased, and was strong, cheerful, and happy.

At the time the specimen was presented to the Society, it was stated that, so far as we knew, this unusual procedure of Dr. Cathcart's was without precedent, and that from the results of the case we had reason to hope that it marked a new era in the local management of malignant disease of the female genital organs. The affection is at best a desperate one, and gynæcologists have been led to adopt a purely expectant local treatment, because the manipulations necessary to make applications may be followed by serious and, possibly, even by fatal hemorrhage. But since the last meeting of this Society no less than three important papers have appeared upon this subject. The first is by Dr. Munde,* the second by Prof. A. R. Simpson, of Edinburgh,† and the third by Dr. Alfred Wiltshire, of London.‡ Though the second paper reached America before that of Dr. Munde, owing to the delay in the appearance of the *American Journal of Obstetrics*, and though Dr. Cathcart performed his operation in June last (1872), the priority of suggestion must be awarded to Prof. Simon, of Heidelberg.

During the last two weeks we have had another opportunity to try this method of treatment; and the portions of the growth which were removed are now exhibited to the Society. Though this specimen itself possesses but little interest, the case is an unusual one, inasmuch as the vagina was the organ primarily involved. The patient was a light mulatto woman, about thirty years old, who was admitted to the Presbyterian Hospital a few weeks ago. She is the mother of four children, the youngest of whom is eight months old. She had always been a healthy woman until about six months before the birth of her last child, when she began to suffer from severe pains in the pelvis. Her labor was normal. She remained in bed for two weeks, and then got up, feeling as well as usual. For two weeks everything went well, when she had a hemorrhage from the vagina. From that time until her admission to the hospital she lost more or less blood every day. At times the discharge was very profuse. It was brought on by the slightest exertion. She became greatly exhausted, much emaciated, suffered from severe pelvic pain, frequent as well as painful micturition, and painful defecation. Two weeks before admission she lost the power of retaining her urine.

Her condition when she entered the hospital in November, 1872, was as follows:

She was greatly emaciated, with a clean, pale tongue, poor appetite, occasional vomiting, constipated bowels, and great pain when they were moved. She complains of severe abdominal and pelvic pains. The belly is not distended, and it contains no tumor. There are no pulmonary or cardiac symptoms.

Vagina.—Immediately within the vulva the finger comes in contact with a ragged, rough, but rather soft tumor, which breaks down easily and bleeds freely when pressed upon. In front of the tumor the finger passes upward about an inch and a half, when the growth is found to be attached to the anterior wall of the vagina. A catheter introduced into the bladder is easily distinguished below the growth; but the anterior vaginal wall is found to be considerably thickened. Above the tumor the cervix uteri is distinguished with some difficulty, and is in the usual situation. The posterior lip seems to be quite smooth, but the anterior is rough and covered with short, irregular outgrowths, which break down under pressure. Immediately below the cervix is the best developed or highest portion of the upper margin of the tumor. Below this is a depression, at the bottom of which the silver catheter in the bladder can be felt. Through this somewhat funnel-shaped opening two fingers can be thrust directly into the bladder. The fundus of this organ is easily reached a little above the upper margin of the opening, while the inner orifice of the urethra is scarcely an inch below the lower one. The posterior and lateral portions of the vagina are not involved. A profuse discharge of blood and thin offensive pus runs from the part. Upon separating the labia, some sloughs are to be seen protruding, and above these is the red, soft, warty tumor which the patient says protrudes when she stands for a little time or strains forcibly.

Though the patient was very weak, and though

‡ *British Medical Journal*, November 2, 1872.

we could not encourage her to hope for more than very temporary relief, it was determined to scrape away all of the morbid growth which could be removed. Being provided with a blunt bone-scraper, an ordinary director with an expanded extremity, a pair of long vaginal scissors, and some Monsel's salt, the procedure was begun. These instruments were but poorly adapted to effect our purpose, and we would suggest that gynæcologists who propose to repeat the operation should provide themselves with a set of Prof. Simon's scoops.* Most of the growth was removed with the bone-scraper and the finger, a Sims' speculum having been introduced into the vagina and a catheter into the bladder, the woman being placed in the semi-prone position. As the operation proceeded, the hemorrhage, instead of increasing, diminished in quantity until we attempted the removal of one of the large masses near the vulvar orifice. Experiencing some difficulty in breaking this down, the pedicle was severed with the scissors. An artery of considerable size was opened, and she bled quite freely. Upon the application of the torsion-forceps the tissue broke down, until more healthy structure was reached, when the flow ceased, after giving the artery a twist. The scraped surface was now covered with Monsel's salt, and a damp sponge, with one side covered with the same substance, was passed into the vagina and allowed to remain there for about four hours. No hemorrhage or abdominal pain or tenderness followed. She remained under observation for nearly two weeks longer, when she was discharged. During this time she seemed to be much better, and had no hemorrhage at all, and less vaginal discharge.

This case is interesting not only therapeutically, but because it furnishes a good example of primary cancer of the vagina; and as such it may be contrasted with the one related to the Society by Dr. Mears about a month since. Some may question the conclusion that the vagina was first affected, since the uterus was involved at the time she came under observation. It was affected to such a slight extent, while the destruction of the vagina and bladder was so great, that the cervix could hardly have been the starting-point of the malignant growth.

It is of course not claimed that the removal of the redundant portions of cancers of the female genitals by scraping will cure the disease. It will only prolong life by diminishing, or completely arresting, the hemorrhages for the time being. But this is no trivial matter. No symptom of the disease is more important than this one, and, without doubt, it has shortened the lives of many of these unfortunate sufferers. At the same time, the discharge is greatly diminished, because the fungous and disintegrating portions of the morbid tissue are not allowed to accumulate. To achieve this is no trifle, as every sufferer from this terrible disease can testify. It is true that the procedure has to be repeated at intervals; but this is no argument against its utility, as in this disease the physician can only hope to prolong life and diminish suffering.

The operation should be performed with caution until its usefulness is fairly established or disproved. It is not difficult to conceive that it may be followed by pelvic peritonitis under some circumstances, or that, in cases in which the disease had existed for a long time, and much tissue destroyed, adjacent organs might be injured, unless care was employed.

THE ACTION OF QUININE ON THE UTERUS.

BY H. G. LANDIS, M.D.,
Niles, O.

THE statement that quinine has a special influence upon the uterus has elicited many expressions of opinion through the journals, which for the most part oppose the views advanced by Monteverdi. I have had an opportunity of testing this influence in over twenty cases during the past year, in a malarial district, and offer the result to the profession as additional testimony. The trials were all made upon the impregnated uterus, and mainly in cases of lingering pains during labor; but it seems very unlikely that an agent purporting to excite or strengthen the muscular action of the womb would act in an essentially different manner on the unimpregnated uterus. I have grouped the cases as follows: I. Those in which quinine effected or seemed to effect a change in the behavior of the uterus; and—II. Those in which it did not. Only the first need be given at length, and a comparison will enable us to determine the amount of influence exerted by the drug. The first three cases show its action during labor.

I. *No.* 1.—Fifth pregnancy. Lives on the edge of an undrained pond of stagnant water, and is frequently subject to ague. Called at 12.50; found os uteri 2½ inches in diameter. Pains poor and infrequent, and no change by 2.10, when I gave quin. sulph. gr. v, and ruptured the membranes. In half an hour the pains became strong and frequent, and the child was rapidly expelled at 2.50.

No. 2.—Third pregnancy. Lives next door to No. 1. Called at 8 A.M.; found os uteri 1¾ inches in diameter. Pains feeble, and ten minutes apart. Dilatation, however, was complete at 10.30, when the pains became still feebler. At 11 gave quinine gr. vj; in ten minutes the pains grew strong, and in ten minutes more the head was born, going through the whole mechanism of descent in that time.

No. 3.—Fourth pregnancy. Lives on the edge of a partly-cleared woods, within a stone's-throw of a sluggish river, and on very low, swampy ground. Has been nursing a child in a bad attack of remittent fever. Labor began early in the afternoon. Pains were trifling, and at 5.45 P.M. the os was barely one inch in diameter. At 6.30 gave quin. sulph. gr. iv. Pains increased in twenty minutes. Dilatation was complete at 7, and birth occurred at 7.15, after a long and continuous pain.

It will be seen at once that these cases have one feature in common, viz., the presence of a malarial atmosphere. In the next three an attack of malarial poisoning was present at the time.

No. 4.—Second pregnancy. Six and a half months advanced. Has had two chills, and is now threatened

with miscarriage. Has some flooding, but the os uteri is but little patulous. Gave her small doses of quinine, relying on morphia and chloral with gallic acid to check hemorrhage. On the next day the flooding had ceased, but there was a good deal of pain, and the urine had to be withdrawn by catheter. On the next day, when a chill would naturally have occurred, the flooding was renewed profusely, and the os dilated so as to allow the introduction of the finger. I gave quin. sulph. gr. v, and morph. sulph. gr. ½, every three hours, which soon ended the whole trouble. Quinine was continued at intervals, and gestation proceeded undisturbed until full term.

No. 5.—Third pregnancy. Was attacked August 16 by remittent fever, being nearly at full term. Vomiting was severe, and she was delirious during the first night of the fever. Morphia and bismuth were alternated with full doses of quinine. She had abdominal and lumbar pains from the commencement. After the first day the fever was kept in check by quinine, and on the 21st, although feeling almost entirely well, labor began naturally. The pains were excellent, and the labor short. Quinine was then stopped, and on the 25th, nine days from the first onset of the fever, nausea, delirium, and a violent exacerbation recurred, which was in return controlled by quinine. It is interesting to notice how little the fever interfered with the labor, but, in the light of the next case, a part of this result must be ascribed to the quinine.

No. 6.—Fifth pregnancy. Had had remittent fever for three weeks. Was at full term, and had had hemorrhage and teasing pains for two days. The os uteri was slightly dilated, and it was evident that nothing interfered with the termination of labor but inertia of the womb. I gave quinine gr. ij with tinct. ferri chlor. every four hours, and in twenty-four hours effective labor came on, and was soon terminated.

These are the only cases in which I could fairly attribute any useful action to quinine in regulating uterine contractions, excepting one in which two doses given half an hour apart caused copious vomiting, with the not uncommon effect of relaxing the parts and accelerating labor.

II. It would be tedious and unnecessary to describe at length the cases in which quinine had no perceptible effect. They occurred in more healthy neighborhoods and in women uninfluenced by ague. The drug was given in this series only for lingering inefficient pains during the first or second stages of labor, which was an occurrence not of unusual frequency, as I have notes of double the number which were entirely normal, though delivered during the same period and in a malarious season. One case will suffice. Eight grains of quinine were given after partial dilatation of the os, the pains being tolerably regular but very inefficient, only wearing out the woman's patience. No effect whatever was produced for six hours, when a grain of opium was given, and labor terminated in two hours. The inference I have drawn from these cases is that inertia of the womb in labor or threatened abortion can be successfully combated by quinine only, in the presence of a definite attack of ague or a decidedly malarious atmosphere, but that it has no perceptible effect on the uterus uninfluenced by this disturbing agent.

Dr. Voisin, formerly physician to the Bicêtre, died in November last, at the age of nearly eighty.

TRANSLATIONS.

VON OPPOLZER'S LECTURES ON DISEASES OF THE ŒSOPHAGUS.

Being the latter portion of the first part of the second volume of Oppolzer's Vorlesungen über specielle Pathologie und Therapie, Erlangen, 1872.

Condensed from the German of Dr. Emil Ritter von Stoffella

BY DR. J. SOLIS COHEN.

GENERAL REMARKS UPON THE DISEASES OF THE ŒSOPHAGUS AND THE METHODS OF INVESTIGATING THEM.

DISEASES of the œsophagus are much less frequent than diseases of the rest of the digestive tract,—a circumstance attributed by Oppolzer to the thick epithelial coat with which the œsophagus is covered, and to its comparatively moderate vascularity. Both this infrequency of disease, and the difficulties so often encountered in determining the actual abnormal condition of the œsophagus, render it evident that the present state of our knowledge of œsophageal affections leaves much to be desired. As long as medical investigation progressed no further than symptomatic manifestations, all these diseases were included under the general head of dysphagia, subdivided into inflammatory, spasmodic, paralytic, organic, and "lusoric" (or, as Hamburger has recently sarcastically termed it, illusoric) (phantom?) dysphagia.

Recent scientific research has brought anatomico-pathological investigation to bear on these affections, and enables us to comprehend them much better than formerly, though not with the exactness characterizing our knowledge of the disorders of many other organs. The invention of the œsophagoscope, and the recent application, by Hamburger, of auscultation to the study of the œsophagus, give every promise of substantial additions, before long, to our knowledge of these diseases.

The most prominent indication of disease of the œsophagus is *dysphagia*,—difficulty of swallowing. In most instances, deglutition is impeded to a greater or less degree, partly on account of pain in the act, partly on account of some mechanical obstacle, tumor, constriction, spasm, or paralysis, etc., as the case may be. Too much weight, however, must not be accorded to this symptom, inasmuch as its cause may lie altogether outside of the œsophagus, on the one hand, and, on the other, because extensive disease of the œsophagus may exist without giving rise to the slightest impediment in swallowing.

Pain is sometimes entirely absent in œsophageal diseases, or present merely as a dull ache, this exemption being explained by the slight sensitiveness of the organ. Severe pain exists only in cases of abscess and in specially severe inflammations, such as result from scalds, or poisoning with caustic substances; while in simple catarrhal inflammation, or even pustulous inflammations (as in smallpox, etc.), there is, as a rule, no pain. Pain is sometimes localized; usually at the lower end of the tube, or beneath the manubrium sterni; and this may lead to error, if it is always inferred that the seat of pain indicates the seat of disease. The assertion of the patient as to the exact seat of pain cannot always be fully relied on, or, at least, only with a certain amount of probability as to its designating the seat of the disease in the œsophagus.

Regurgitation of food is another accompaniment of œsophageal disease, especially when dysphagia exists.

Rumination—chewing the cud, as it were—is a symptom which has been observed to accompany congenital dilatation of the œsophagus.

Auscultation of the œsophagus, so practically applied by Hamburger, gives the following results, in brief, in the normal subject:

1. *In the neck.* Listening through a stethoscope placed upon the neck in the vicinity of the hyoid bone, while the patient is swallowing fluid, we hear a strongly-marked metallic gurgling, due to the commingling of air with the swallowed fluid.

2. *In the thorax.* If the auscultation is made over that region of the œsophagus extending from the level of the cricoid cartilage to that of the eighth rib, we hear during deglutition a sound as if a small but firm spindle-formed body, circularly compressed by the œsophagus, was suddenly shoved noisily downwards. This last sound (the deglutition-sound) is either the sound of a smoothly-slipping substance, or that of the so-called clucking, in which case it is so loud that it masks the entire act of deglutition, and renders its auscultation impossible. The ear must be placed upon the posterior wall of the thorax, to the left of the vertebral column, because, ausculted on the right side, the sound is not so clear, but is dull, and as if coming from a considerable depth.

If the œsophagus is diseased, these auscultatory phenomena undergo many obvious modifications. Thus, for instance, in case of marked stricture, or rupture of the œsophagus, or obstruction by impacted foreign body, or obstruction from retention of the bolus in the pocket of a diverticulum, or also in case of paralysis or organic dilatation, we find that the act of deglutition cannot be detected by auscultation below a certain point, while it is distinct enough above that point. At other times an adventitious sound, such as that of friction, accompanies the smooth normal sound of deglutition, indicating roughness of the inner surface of the œsophagus, such as might accompany croup or diphtheritis of the œsophagus, the pustules of smallpox, large ulcers with ragged edges, polypous excrescences, etc. Under other conditions there is a hissing or rustling sound, or a sound of sprinkling, or leaking, from which we may learn that the bolus does not acquire its normal spindle-like form, or that deglutition does not take place with normal rapidity. Then, again, we may learn from auscultation that the bolus does not pass vertically downwards as it should do in a condition of health, but that it takes an oblique direction towards the left or the right, or rises upwards again. This oblique deviation may be due to aneurism of the aorta, or to exostosis of the vertebræ.

Inspection is only of occasional value in diagnosing affections of the œsophagus. Tumors and abscesses are sometimes rendered prominent, and sometimes we observe the outlets of œsophageal fistulæ. Inspection with the œsophagoscope is so difficult of execution, and usually so painful to the patient, that it can be resorted to with success only in the very rarest cases.

Palpation is limited externally to the region of the neck, and may detect the seat of pain or the seat of impaction of a foreign body. Mediate palpation is performed by the insertion of the œsophageal sound, the operation being known as catheterization of the œsophagus. These explorative examinations must be made with great care, lest by the exercise of too much force we rupture the organ or its mucous membrane. By this method we learn whether the direction of the œsophagus be normal; whether there is a stricture, or a diverticulum; whether its calibre is obstructed by a foreign body or a neoplasm; or we may determine the locality of an ulcer or of inflammation. The presence of pus or of blood on the end of the instrument is also important in a diagnostic view.

Simultaneous auscultation and catheterization is of great importance, as demonstrated by Hamburger. A peculiar tone is heard to follow the passage of the instrument, which can be utilized in locating more exactly the seat of various local affections, and in making topical applications to them.

(To be continued.)

Sick-Headache (*British Medical Journal*, December 21, 1872).—In a report on the treatment of this distressing affection, Dr. Wilks recommends three remedies. To cut short an existing attack, he gives bromide of potassium in doses of gr. xv to xx. One dose is often sufficient. As a prophylactic, he uses the (tincture of?) cannabis Indica, a few drops thrice daily for some weeks.

Of guarana he says,—

"Thirdly, guarana has been introduced to our notice as a remedy for sick-headache, and here, again, we have a very valuable addition to our pharmacopœia. In many instances, especially those of ladies, I have had the most positive assurance given to me of the power of this drug in arresting headache, so that not the slightest doubt can be entertained of its immense value. A dose is usually taken when the headache is approaching; and if this is not quickly successful in arresting it, a second powder is swallowed; after an hour or so, if the remedy is to be useful, the headache has disappeared. I know of several cases in which the greatest enthusiasm is expressed by patients as to its merits. At the same time, I am constantly hearing of cases where it has failed. I am now trying it in smaller doses by daily administration.

"I feel certain that these three drugs—bromide of potassium, cannabis Indica, and guarana—constitute a most important addition to our nervine medicines, and that in them we have remedies against a terrible complaint which, a few years ago, constituted the opprobrium of medicine. I might say that I know of cases where galvanism has very speedily cured a pain in the head; and I can call to mind the case of a lady, where the application of the bisulphide of carbon invariably relieved the most severe headaches."

Intrabuccal Resection of the Inferior Maxillary Nerve (*Ib.*).—Dr. A. Menzel has described in the *Archiv für Klinische Chirurgie* (Band xiii.) two cases in which a portion of the inferior maxillary nerve was successfully excised by the intrabuccal method, proposed in 1858 by Paravicini of Milan. One of the patients was operated on by Dr. Menzel; the other by Dr. Billroth. The incision was made along the anterior border of the ramus of the jaw; and, by tearing through some connective tissue with the finger, the nerve was reached at its entrance into the dental canal. Care should be taken to divide the nerve close to the bone, so that the lingual nerve may not be injured. Dr. Menzel also describes a somewhat similar case, in which he divided both the dental and the lingual nerves by the intrabuccal operation; and he believes that these are the first instances in which the operation was performed on the inferior maxillary nerve in the living subject. The intrabuccal method is said to possess the following advantages: freedom from danger; the possibility of resecting the nerve at a higher point; the absence of cicatrix and of facial paralysis, and of salivary fistula; and the facility of the operation.

Pill for Neuralgia (*Georgia Medical Companion*, Dec. 1872).—

℞ Ext. of hyoscyamus,
Ext. of valerian,
White oxide of zinc, aa ʒj.—M.

Make the mixture into sixty pills. One pill may be taken every three hours. This is an old and favorite prescription of the German and French physicians, and is mentioned in many of their works on therapeutics.

PHILADELPHIA
MEDICAL TIMES.
A WEEKLY JOURNAL OF
MEDICAL AND SURGICAL SCIENCE.

The Philadelphia Medical Times is an independent journal, devoted to no ends or interests whatever but those common to all who cultivate the science of medicine. Its columns are open to all those who wish to express their views on any subject coming within its legitimate sphere.

We invite contributions, reports of cases, notes and queries, medical news, and whatever may tend to increase the value of our pages.

All communications must bear the name of the sender (whether the name is to be published or not), and should be addressed to Editor Philadelphia Medical Times, care of the Publishers.

PUBLISHED EVERY SATURDAY BY
J. B. LIPPINCOTT & CO.,
715 and 717 Market St., Philadelphia, and 25 Bond St., New York.

SATURDAY, FEBRUARY 1, 1873.

EDITORIAL.

MEDICAL AND SURGICAL HISTORY OF THE REBELLION.

IN the U. S. Senate, on Friday, January 17, 1873, Senator Anthony, from the Committee on Printing, reported the following resolution from the House of Representatives, without amendment, and asked for its consideration and passage. "By unanimous consent" (we quote from the *Congressional Globe*) "the resolution was considered and agreed to, as follows:"

"*Resolved, by the House of Representatives* (the Senate concurring), that of the five thousand copies of the medical and surgical history of the war authorized to be printed by joint resolution of Congress, approved March 3, 1869, two thousand copies shall be for the use of the House of Representatives, one thousand for the Senate, and two thousand for distribution by the Surgeon-General of the Army."

We are informed that Part First of the Medical and Surgical History of the Rebellion, the distribution of which is here provided for, consists of two large quarto volumes, with an aggregate of 1800 pages, twenty-five plates, and three hundred wood-cuts. The first comprises the classified consolidation of the sick reports for the whole period of the war, with which is bound an appendix of 365 pages, containing the medical directors' reports, and other documents. The second, or surgical volume, treats, in five chapters, of the special wounds and injuries of the head, face, spine, neck, and chest.

The following draft of a bill had been brought in by Senator Logan, on the 13th:

"*Be it enacted by the Senate and House of Representatives of the United States of America in Congress assembled*, That the Secretary of War be, and hereby is, directed to have printed, at the Government Printing-Office, one thousand copies of the descriptive anatomical catalogue of the Army Medical Museum, in folio, for distribution to the contributors and collaborators of the museum.

"SEC. 2. That the amount of twenty thousand dollars, out of moneys in the Treasury not otherwise appropriated, be, and hereby is, appropriated for the preparation of the necessary engravings and lithographs for said catalogue, under the supervision of the Surgeon-General of the Army."

We understand that this volume will comprise an account of the crania in the Army Medical Museum, handsomely illustrated, with the measurements of over one thousand skulls. It is greatly to be hoped that the importance of this most valuable addition to the scientific contributions from the Surgeon-General's office will be so clearly presented in Congress as to set aside any utilitarian opposition, and that the work will be at once authorized.

A DESIRABLE MEASURE.

WE observe, with much satisfaction, that an attempt is to be made, under the auspices of the Lancashire and Cheshire Branch of the British Medical Association, to obtain such statistics as may throw light upon the now obscure subject of the duration of infection. In a recent editorial, the *British Medical Journal*, after speaking of the inconvenience to school-teachers and parents, employers and employés, caused by uncertainty on this point, says that

"There are doubtless not a few practitioners who, when they are asked questions on this subject, boldly confess their ignorance,—a course which may raise them individually in the estimation of sensible people, but which will hardly raise the credit of medical science. Others, again, fix an extreme limit by way of being 'on the safe side;' and a third class endeavor to come as near the truth as their own experience or that of their *confrères* will allow. Naturally, there are great differences in these latter opinions as expressed to the public, and thus arises another source of the contemptuous opinion which is held of medicine by men of science."

The committee have had circulars printed for distribution to the profession, and schedules for recording cases observed, these circulars and schedules being suggestive of the points to be noted. Copies of them can be had on application to the Honorary Secretary of the Committee, Dr. Haddon, of Monkshall, Eccles, Manchester. We trust

copies of them may be sent to this country, in order that the same line of inquiry may be set on foot here.

And yet—under what auspices? We can scarcely think that the American Medical Association has within it any machinery adapted to this task, and we do not know whether any of the State or County Societies can undertake it with better prospects. Here, as often before, is felt the need of an organization which should be able to appeal to the profession with authority, and to claim its hearty and general co-operation,—a representative body, which should speak in the name of the physicians of the United States, by their appointment. Looking back over the history of our Association and its work, we do not think the most sanguine of its conservative friends can promise us any very satisfactory result in regard to the matter in question.

THE CENTENNIAL COMMISSION.

SOME time since we received from the office of the commissioners a copy of the minutes of the proceedings of the corporators for Pennsylvania of the Centennial Board of Finance, together with a circular from the President of the Board, asking us to give the cause the most earnest and effective support.

We hope, and we do not doubt, that the profession in this city and throughout the United States will take an active share in forwarding an object so patriotic. And yet it has not seemed to us that we ought to fill our columns with matter to which our readers would have such ample access in the secular journals. We shall therefore merely say that the plan has our most hearty concurrence, and our sincerest wishes for its brilliant success.

It may be well to mention again that the following gentlemen have been appointed the subscription committee for the medical profession: Dr. John B. Biddle, *Chairman;* Drs. Francis Gurney Smith, Jr., John Neill, Caspar Wister, and Edward Hartshorne.

SMALLPOX AGAIN.

UNPLEASANT accounts reach us of the prevalence of smallpox in Boston, and of a less severe visitation of it in Baltimore. The probabilities are against its attacking the people of this city with any degree of virulence this winter; but it would be the part of wisdom for our authorities to be on the watch against it. A thorough carrying out of sanitary measures among the lower orders, the greatest care to vaccinate all the unprotected, wherever found, and the prompt isolation of any cases of the disease as soon as they occur, may save a vast amount of trouble. Last winter's lessons should not be lost upon us.

PROCEEDINGS OF SOCIETIES.

BIOLOGICAL AND MICROSCOPICAL SECTION OF THE ACADEMY OF NATURAL SCIENCES.

January 6, 1873.

DIRECTOR W. S. W. RUSCHENBERGER, M.D., in the chair.

PRESENT, Drs. J. G. Hunt, McQuillen, I. Norris, and Richardson; and Messrs. Corlies, Warner, and Trueman.

The Corresponding Secretary, Dr. J. H. McQuillen, presented a fine specimen of Nottingham tripoli, donated to the Section by Dr. Philip T. Tyson through Dr. J. Cheston Morris.

The report of the committee upon Dr. Fricke's paper, recommending it for publication in the *Philadelphia Medical Times*, was accepted, and the committee discharged.

Dr. J. G. HUNT called the attention of members to some beautiful specimens of vegetable structures which he had adjusted beneath the microscope, and remarked that the popular method of studying botany fails to give the student much definite information in regard to the structure of plants. To ascertain the name of a plant by reference to some "analytical key," then to press it between brown paper and entomb it in an herbarium, should not any longer be regarded as scientific botany.

Minute organization, which undergoes no change, at least none during the ordinary life of the student, and not the ever-changing classifications of authors, shall be the subject of my remarks this evening.

I hold in my hand a portion of Sarracenia vasiolaris, obtained from Florida. Its habitat is the swamps of hot countries, and its appearance even to ordinary observation is peculiar and beautiful. From two to five or six radical leaves constitute all the foliaceous parts of the plant, and these leaves are fashioned into hollow vessels, which have been compared to pitchers. Commencing near the ground in a narrow cavity, they gradually enlarge towards the top to an inch or two in diameter, and are found sometimes eighteen inches in length. Overhanging this wild forest-pitcher is a lid, formed by a prolongation of the leaf. It is to the minute structure of the *internal* surface of this pitcher that I will ask your attention. We will commence at the top, and travel, in thought, to the bottom. There are preparations on the table, stained with aniline, and mounted in damar, to illustrate its structure.

A zone of stiff spines surrounds the pitcher in its upper part, and extends about an inch downwards; each spine projects into the cavity about the one-sixtieth of an inch, while the points of all are directed downwards. These spines are exceedingly acuminate, much more so than it is possible to make a needle, and their walls are ribbed with exceedingly delicate lines of cell-deposit, which converge to the points, looking not unlike the so-called lines on some diatoms, only these are true lines.

It is very curious to observe how these spines diminish in size but increase in number as we descend the pitcher, until we come to a second zone quite encircling its cavity, which is here covered entirely by diminutive spinous projections, each about the one-six-hundredth

part of an inch long and remarkably uniform in size, and so closely imbricated as to resemble, in arrangement, the scales on a fish. It requires delicate optical arrangements to detect all the beautiful details of structure in this middle zone of Sarracenia, and oblique light, in which so many microscopists delight, will be found necessary to reveal the delicate converging striations on the spines.

The two zones I have mentioned, while structurally dissimilar, are dotted quite thickly, but especially the upper one, with beautiful little glands, which sparkle like rubies when properly tinted with aniline. These glands are imbedded just under the epidermis, and open by minute orifices between the spines. Several straight-sided cells, arranged around little cavities, build up their walls.

Stomata, too, are scattered sparingly through the upper zone of spines, and each stomatal cell is engraved with faint lines which converge towards their free margins.

The third or lowest zone carries on its surface slender flexible filaments of far greater length, and placed more thickly together; a dense forest, in fact, whose innumerable filaments, curved downwards, interlock with those on the opposite side, making thus a trap across the narrow pitcher, through which an insect might readily enter, but from which it could not possibly escape.

These curious traps are set in the swamps, and we find them often containing many insects which have been lured to drink of the strange intoxication found therein, but, like bigger bugs of other genera, were not able always to retreat.

Method of Investigation.—To examine the surface of our plant simply as an opaque object, would give no conception of its true structure. We must have a process, therefore, applicable to all such investigations. Cut from the plant pieces about half an inch square, and put them in a test-tube with one part water and two parts nitric acid, and heat until the tissues can be separated easily. Then decant into clean water, and wash gently to remove the acid. It will be easy now to separate the tissues with forceps or needles, and those parts which show structure best may be put in clean water preparatory to staining. Make a solution of rose aniline in distilled water to which a little alcohol has been added, and immerse your preparation for one or two days, or until the desired tint is obtained. Have your staining solution quite dilute, and allow time for the tinting. Most stained preparations of both animal and vegetable tissues are worthless, because too much color obscures all delicacy of structural detail. All that I aim at in staining is to differentiate parts which are really structurally dissimilar, but yet so alike in *transparency* as to escape notice without the tinting; and, when used in this way, coloring becomes a more delicate process of discrimination than polarized light. If the staining has been conducted properly, the liquid remaining in the vessel will be quite clear; *all color will be taken up by the preparation.*

Now transfer to camphor-water, in which the specimen thus prepared may be preserved indefinitely, or be sealed up in a cell, using the same liquid for a preservative. Acids or alkalies should never touch an aniline preparation.

This process of examination, or its equivalent, I have practised for ten years, and it gives results which I have not seen equalled otherwise.

If it be desired to preserve the specimen in damar, the process is not difficult. The only hazard is too much structural change by shrinkage, or entire loss of color. Both these calamities may be entirely avoided. Float the preparation from the camphor-water upon a slide, and cover with another glass, and *very gently* tie a string around both; then immerse in absolute alcohol, if you can get it, for a few hours; then transfer to *alcohol and oil of cloves, equal parts*, and when thoroughly saturated, remove the preparation from between the glasses, and, if clean, mount in damar. Nearly all delicate vegetable tissues, if carefully manipulated in this way, may be mounted in damar, and kept *permanently*, —thus avoiding cells, which have been known to leak,— and yet retain all their delicate aniline tinting, without contraction or too great transparency, or other structural alterations, which so often render this kind of work unfit for scientific study.

Mr. WARNER inquired whether it was known what kind of a digestive process, if any, flies and other insects underwent after being caught in the manner described by the leaves of the Sarracenia.

Dr. Hunt replied that although the flies went into the cavities of the leaves, and, not being able to find their way out, died there, we are as yet destitute of a single atom of evidence that the plants accused of the diabolical cruelty of fly-catching are really guilty of that crime.

Mr. Warner observed that, since this process of fly-catching and killing had evidently been going on in this same way for centuries, it seemed to him probable that there was some object in the operation, and therefore that it formed some unexplained part in that grand scheme which was called, when he was a boy, "the economy of nature."

Dr. Hunt added that the leaves of the Dionœa or Venus' fly-trap shut, it is true, upon insects, and sometimes crush them in their folds; but these supposed carnivorous leaves will close upon a piece of cheese, or a small gravel-stone, with equal readiness, and compress such inanimate objects with equal force.

Dr. RICHARDSON inquired what were the further steps of the process by which such admirable mountings in damar varnish as those exhibited were finally completed.

Dr. Hunt answered that, when the specimens were prepared, a slide was to be warmed, a pretty large drop of the damar varnish placed upon its middle, and heated until sufficiently hardened to no longer flow freely; then add another drop of the varnish, immerse in this the specimen, heat the thin glass cover and lay it on, avoiding air-bubbles, and finally harden the varnish to complete firmness by the continued application of the spirit-lamp. Finish by cleaning off the excess of varnish with a soft rag dipped in alcohol, and putting on a smooth ring of the damar, and not of asphaltum varnish.

Dr. J. G. HUNT also showed beneath the microscope specimens of a variety of the common truffle (Tuber nitidum (?), discovered near the Schuylkill River, above Philadelphia, and stated that, as far as he was aware, this was the first time the fungus had been found growing wild in America.

Dr. Hunt likewise called the attention of the members to a modification of the German method of imbedding, as recently described by Dr. Tyson, which consisted in using the ordinary brass section-cutter as a mould for the paraffine, instead of making a mould for that substance out of a cone or box of paper.

Dr. Richardson remarked that this so-called improvement would have the great disadvantage of preventing the operator from cutting his thin sections in any plane except that which happened to lie exactly at right angles to the axis of the section-cutter. Practically he had found it exceedingly advantageous to be able to turn in the fingers the lump of paraffine containing, for example, a piece of kidney, so as to cut first a longitudinal, then a transverse, and finally a diagonal section of the uriniferous tubules.

Dr. Hunt admitted that this cutting thin slices in various directions might be useful in some cases, but

observed that without the aid of the section-cutter it was almost impossible to obtain thin sections of half an inch or more in breadth, and that he believed it was only by the preparation and study of such specimens that we could penetrate the secrets of pathology and discover wherein consisted the exact primary alteration of structure which occurs, for example, when healthy tissue first becomes the seat of cancerous growth.

At the suggestion of Dr. Hunt, it was resolved on motion that a committee be appointed to consider the subject of holding a meeting for the purpose of exhibiting and comparing microscopes, microscopic apparatus, and specimens; to which duty Drs. Richardson, J. G. Hunt, and I. Norris, Jr., were appointed.

PHILADELPHIA COUNTY MEDICAL SOCIETY.

Vice-President J. G. Stetler in the chair.

At a conversational meeting held January 8, 1872, at 8 o'clock P.M.,

Dr. W. B. Atkinson referred to a case of hæmaturia of a severe character. To-day a large amount of blood and urine was passed, which when tested was found to contain albumen. The patient had an attack three years ago of a similar character. He had recommended to the attending physician the use of benzoic acid.

Dr. H. Y. Evans asked Dr. Atkinson upon what theory he gave the benzoic acid.

Dr. Atkinson said he had prescribed it on the authority of Carl Braun of Vienna. He had used it in other cases with success.

Dr. O'Hara said that, previous to the appearance of albumen in the urine, one can detect an antecedent stage of Bright's disease by the use of tinct. of galls as a test; there is an immediate precipitate of blood extractives, and it is positively asserted that one can thus be prepared for the advent of the albuminuria in all cases. In pregnant cases the disease disappears frequently of itself after labor. The remedies are numerous, but iron, quinine, and belladonna, and various other remedies, are useful. He could not understand the philosophy of using benzoic acid.

Dr. Atkinson said he had seen the albuminuria cease before delivery in cases of pregnancy, and that the patient's condition was markedly improved by its use. Dr. Atkinson asked Dr. H. Y. Evans in what manner he would treat hæmaturia.

Dr. Evans replied that he would treat it on general principles,—improve the patient's condition, by means of large doses of the tincture of the muriate of iron, opium, alcohol, and quinia.

He had seen in *The Medical Times and Gazette* nitro-muriatic acid highly recommended.

Dr. O'Hara remarked, if the albumen disappeared in these puerperal cases a few days prior to labor, according to his understanding, benzoic acid would have a lifting or motive power. He did not consider the Bright's disease of pregnancy due to dyscrasia, but rather to pressure and tension, with passive congestion of the kidneys and its associate organs. It would be found that albuminuria had no necessary connection with convulsions. A not uncommon form of convulsions was that associated with the casting-off of a fœtus at four, five, or six months, and which he had generally found fatal, and the urine not albuminous.

Dr. Atkinson made the inquiry,—if albuminuria in pregnant women was due to pressure, why did they not all have it?

Dr. Stetler asked Dr. Atkinson whether the albumen was more copious than he would expect to find in hemorrhage, especially where a considerable amount of the serous portion of the blood or liquor sanguinis had escaped; also whether he had made a microscopic examination of the urine.

Dr. Atkinson replied that no microscopic examination had been made. The urine was obtained as free from blood as possible. In reply to Dr. Welch, he stated that the blood was from the kidney, and that there was no stone in the bladder.

Dr. N. Hatfield remarked that blood coming from the kidney would be disintegrated by the urine, and would not coagulate. It was most likely from the bladder.

Dr. Evans said that, as a rule, the blood from the kidneys in chronic hæmaturic cases is so altered by the acids of the urine by the time it passes from the bladder that it does not coagulate; though in cases of mechanical violence, almost pure blood will pass, coagulating without artificial means.

At the stated meeting of the Society, held January 15, 1873, at 4 o'clock P.M., Dr. J. G. Stetler, Vice-President, in the chair, the following officers and delegates were chosen by ballot for the ensuing year:

President, Dr. William B. Atkinson.
Vice-Presidents, Dr. Henry H. Smith, Dr. H. St. Clair Ash.
Recording Secretary, Dr. Henry Leaman.
Assistant Recording Secretary, Dr. Lemuel J. Deal.
Corresponding Secretary, Dr. William Goodell.
Treasurer, Dr. William M. Welch.
Censor, Dr. N. L. Hatfield.

REVIEWS AND BOOK NOTICES.

Surgical Diseases of Infants and Children. By M. P. Guersant, Honorary Surgeon of the Hôpital des Enfants Malades, Paris, etc. Translated from the French by Richard J. Dunglison, M.D. 8vo, pp. 354. Philadelphia, Henry C. Lea, 1873.

The great reputation of the author of this work was well earned. We can bear witness to the gentleness and skill with which he ministered to the little patients in his hospital-wards, and to the value of the lectures he gave. But since these lectures were published in the original, surgery, both as a science and as an art, has made great strides; and the practitioner of the present day will find even this excellent translation of little use. As an addition to the classical literature of the profession, however, we give it a cordial welcome.

Aids to the Diagnosis of Diseases of the Kidneys. By W. R. Basham, M.D. 8vo, pp. 48. Philadelphia, Lindsay & Blakiston, 1872.

"It has appeared to the author that what has been of use to himself may be of advantage to others." This, the author's initial sentence, is the keynote of his effort. The work is small,—forty-eight pages,—and contains ten plates; each plate giving six microscopic views. The text is but the explanation of the plates,—the story of the pictures, which refer to actual cases, forty-one in number, detailed in the book. This is an ingenious way of impressing microscopical appearances upon the mind; the book being only of use, however, to the practitioner who is also a close investigator and user of his microscope in daily work. To such it will prove highly suggestive, and a real aid. Not so bulky as to repel, but short and concise, such a book not only aids us in clearing up doubtful diagnoses, but suggests, oftentimes, the true explanation of cases whose real nature has been totally unsuspected.

BOOKS AND PAMPHLETS RECEIVED.

The Pharmacopœia of the United States of America. Fifth Decennial Revision. By authority of the National Convention for revising the Pharmacopœia, held at Washington, A.D. 1870. Small 8vo, pp. 383. Philadelphia, J. B. Lippincott & Co., 1873.

Diseases of the Ovaries: their Diagnosis and Treatment. By T. Spencer Wells, Fellow and Member of Council of the Royal College of Surgeons of England, etc. etc. 8vo, pp. 478. New York, D. Appleton & Co., 1873.

The Philadelphia Medical Register and Directory. Edited by John H. Packard, M.D., Secretary of the College of Physicians of Philadelphia. Third Edition. Crown 8vo, pp. 307. Philadelphia, Collins, Printer. 1873.

Report to the Secretary of War in regard to Quarantine on the Southern and Gulf Coasts. By Harvey E. Brown, Assistant Surgeon U.S.A. 8vo, pp. 117. Senate Document.

Illustrations of the Influence of the Mind upon the Body in Health and Disease. By Daniel Hack Tuke, M.D., M.R.C.P., etc. 8vo, pp. 415. Philadelphia, Henry C. Lea, 1873.

The Practice of Surgery. By Thomas Bryant, F.R.C.S., Surgeon to Guy's Hospital. With 507 Illustrations. 8vo, pp. 984. Philadelphia, Henry C. Lea, 1873.

Contributions to Mental Pathology. By I. Ray, M.D., Author of "Medical Jurisprudence of Insanity," etc. 8vo, pp. 558. Boston, Little, Brown & Co., 1873.

GLEANINGS FROM OUR EXCHANGES.

Artificial Placental Respiration (*Medical Examiner*, Dec. 15, 1872).—At the meeting of the Chicago Society of Physicians and Surgeons, held Nov. 12, a paper, avowedly a suggestion only, was read by Dr. John Bartlett, entitled *Artificial Placental Respiration.*

Dr. Bartlett suggested, in certain cases in which the after-birth is extracted or extruded before the child, the following practice: *directly upon the detachment of the placenta, immerse it in the fresh, warm, defibrinated blood of some animal, as the sheep; change the blood as often as practicable, and aerate it by means of oxygen gas.*

Dr. Bartlett considered the statements going to show that the life of the fœtus was not momentarily dependent upon the purification of its blood through contact with the maternal circulation, too numerous to be disregarded. Three classes of cases in which the fœtus had for a considerable time survived a separation from the maternal circulation, were cited. In one class, the child maintained life in the dead body of the mother; in a second, the fœtus survived separated from the mother, its relations with the after-birth and membranes being retained; in the third, the child remained alive in utero, while the placenta was without the mother.

The circumstances and conditions under which the fœtus may, for a considerable time, continue its life after the disruption of its placental relations to the parent, seemed to be such as left the after-birth in situation, in some measure, to perform its branchial functions.

Dr. B. proceeded to point out by what simple processes of absorption and exhalation the embryo in the lower forms of vertebrata, and in man in the earliest stages of embryonic existence, was nourished. He stated that the relation of the placenta of the chick to the albumen of the egg—its immersion in a fluid through which it absorbed oxygen and exhaled carbonic acid—was exactly such as he proposed to establish between the fœtus and the blood in which the placenta was immersed.

In regard to the probabilities of the simple immersion of the placenta in arterial blood proving adequate for the temporary respiration of the fœtus, the essayist called attention to the rapidity with which absorption took place through even the smallest abraded surfaces. The placenta presented fifty square inches of serous, and the like extent of fresh surface through which the necessary interchange of gases might take place. In referring to the anatomy of the placenta, the language of Owen was quoted: "The placental inter-communication is carried on by the contact of the fœtal capillaries with the *maternal extravasated blood.*" In this expression, Dr. Bartlett regarded his suggestion as foreshadowed.

Artificial placental respiration would prove available in those cases of placenta prævia in which the after-birth is detached, whether by the efforts of the uterus, or by the accoucheur. It might also offer an additional chance of resuscitation to the asphyxiated child, where the placenta is also delivered.

On account of the difficulty of obtaining blood of an inferior animal just when needed, Dr. Bartlett suggested that the addition of phosphate of soda and oxygen gas to water might render it a substitute. In some cases, the blood escaping from the mother might be made use of.

Prevention of Miscarriage by Hypodermic Injections of Morphia (*American Journal of the Medical Sciences*, Jan. 1873).—Dr. A. B. Isham, of Cincinnati, after detailing three cases of success obtained by this plan, says,—

"All the advocates of opium, with the exception of Tyler Smith, Byford, and Tanner, advise its administration per rectum. This is probably because the irritable stomach so common in cases of threatened miscarriage may not tolerate so nauseous a medicine as opium. In the manner of administration may have been the small measure of success. It is well known that medicaments introduced into the rectum act in a very uncertain manner; and it will be readily seen how opium or its alkaloids, given *per orem* to a patient vomiting and retching, might fail to avert a miscarriage. Just where these means have failed and will fail again, is where the hypodermic injections would prove invaluable.

"It is useless to enjoin quiet. The patient is not likely to be quiet, suffering the pains incident to uterine expulsive efforts, her mind perturbed by fears for her own welfare and that of her child. Too often, too, the fruit of conception is regarded as an incumbrance, which it would be happiness to lose, and constant activity is one of the most popular recipes to the attainment of such end. Cold applications, leeching and blood-letting, would prove in most instances a waste of precious time; besides, at this day, such practice would be esteemed a barbarity, and not without some reason.

"The prime elements of danger to the life of the fœtus are—*first*, muscular contractions of the uterus, and *second*, hemorrhage. The latter most commonly results from the operation of the former; but it matters nothing as to the many and various causes tending to produce these phenomena. Considerations of safety imperatively demand a speedy arrest of uterine muscular action and hemorrhage, securing which, we may go about investigating and correcting the causes with comparative leisure.

"The use of morphia by hypodermic injection is the most speedy and certain means we possess of effecting such desiderata. It will do even more. Its influence

spreads over the brain, and at the same time that it suspends contraction of the uterine muscular fibres it insures quiet and rest to the whole system, even against the patient's will. It is applicable to any case of threatened abortion, and I believe that its general use would render success at least equal, if not the rule, instead of the exception, as now announced by obstetricians. Of course I am aware that there are occasional individuals who do not well bear the exhibition of opium in any form, but I hold with Byford (Theory and Practice of Obstetrics, p. 171): 'I do not forget, in thus speaking freely about the use of opium, that peculiarities in some persons make it almost useless; yet I remember the unreliability of other remedies in these cases, and risk such disagreements.' "

The Pathology of Cerebral Hemorrhage (*British Medical Journal*, Nov. 9, 1872).—Dr. Zenker, of Erlangen, in a communication made to the last meeting of the Society of German Naturalists and Physicians, confirms in its essential points the statement made several years ago by Charcot and Bouchard, and by Dr. H. Charlton Bastian, that the disposition to cerebral hemorrhage consists in the formation of minute aneurisms. Having examined all the cases of spontaneous cerebral hemorrhage that have come under his notice during several years, Dr. Zenker in every instance found miliary aneurisms, both in the wall of the hemorrhagic deposits, and in other parts of the brain. They appear to the naked eye as little fluctuating tumors as large as a pin's head (rarely larger), and assume all the ordinary forms of aneurism. Usually the inner coats of the vessel give way, and a dissecting aneurism is formed. The disease may remain at this stage for some time, or there may even be recovery, a small pigmentary mass being left. In other instances, all the membranes burst, and hemorrhage into the brain takes place.

As to the origin of these minute cerebral aneurisms, Dr. Zenker does not entirely agree with MM. Charcot and Bouchard. These observers have called in question the dependence of these aneurisms on atheromatous degeneration; Zenker, however, is convinced that they have their origin, just like aneurisms of the larger vessels, in atheromatous disease of the inner coat of the arteries. These minute aneurisms may indeed be present, without any evident sign of disease in the arteries at the base of the brain. On microscopic examination, however, of the aneurisms and of the arterial twigs on which they are seated, the inner coat is found to present changes corresponding to the uneven thickening which occurs in atheroma of the larger vessels. Thus the researches of Charcot and Bouchard do not subvert the old doctrine of the dependence of cerebral hemorrhage on vascular degeneration, but give it an important confirmation.

Fœtal Femur imbedded in the Uterus. By Dr. Evory Kennedy, late Master of the Dublin Lying-in Hospital (*The Doctor*, Sept. 1, 1872).—A lady was brought to me from the country, anæmic, wasted, and with a countenance expressive of pain and suffering. She had a constant fetid vaginal discharge, purulent, and occasionally sanious. She was said to have miscarried a year before. She complained of pelvic distress, with lumbar pains and frequent micturition. On vaginal examination, the uterus was found about double its natural size. The os was slightly patulous, and a solid hard resistance was experienced on introducing the finger. The os was gradually dilated with a two-bladed uterine dilator constructed for the purpose, and a bony substance was distinctly felt traversing the neck of the uterus at the junction with the body of the organ. This was so deeply imbedded in the walls of the uterus that neither extremity could be dislodged. I introduced a pair of small beaked bone-forceps, constructed for the purpose, broke the bone across, and extracted piecemeal the femur of a fœtus of about four months' development, which had been all the time imbedded in the walls of the uterus, which was converted into an abscess by the presence of what should have been its natural occupant, thus forming an unnatural nidus in its walls in place of its cavity. The discharge subsided, and the lady recovered her usual health; but the look of health was never quite restored. She, however, bore children after an interval of six years, and the uterus appeared to have quite regained its normal condition.

The Circulation in the Spleen (Olga Stoff and Sophie Hasse, of Petersburg: *Centralblatt f. die Med. Wiss.*, No. 48, 1872).—These two ladies have performed their investigations in the laboratory of Prof. Frey, in Zurich, who corroborates the statements and conclusions drawn from their work.

The object of the investigations has been to decide between the assertions of Billroth, Schweigger, Seidel, and Kyber, and those of W. Müller and Frey.

The former hold that the circulation is performed in an unbroken circuit, while the latter contend that between the finest arterial capillaries and the beginning of the venous blood-vessels there is a system of lacunæ through which the blood passes on its way from the arterial to the venous system.

The spleens of a variety of animals, beasts, birds, and fishes, as well as of man, have been examined by Stoff and Hasse. Uninjected preparations are hardened in "Müller's fluid" and alcohol. Thin sections are then made, and colored with carmine or hæmatoxylin.

In such preparations, lymph-cells, as well as blood-corpuscles, were easily found, lying "free in the meshes of the reticulum of the pulp. This arrangement is still more distinctly seen by the careful use of the hair-pencil upon the preparation."

In the Malpighian corpuscles, however, the reticulum is found to contain no red blood-corpuscles in its meshes.

The lacunar system is especially well seen in specimens injected with the gelatine mass. In such preparations these observers found only once the direct passage of an arterial capillary into the initial portion of a capillary vein. In all other cases the existence of the intermediate lacunar system was rendered very clear.

Effect of Stimuli on the Secretion of the Parotid Gland.—Mr. P. Butler Stoney, late Resident Physician in St. Bartholomew's Hospital, relates (*Journal of Anatomy and Physiology*, Nov. 1872) some experiments made by him in a case of parotid fistula. The following were his results:

1. That mastication alone stimulates the flow of saliva from the parotid to a considerable extent. 2. That the effects of taste vary with the sapid substance, sugar having no effect, while tartaric acid acts most powerfully. 3. That sapid substances act equally when applied to the tip and base of the tongue. 4. That the effect of mastication and taste together is much greater than that of mastication alone. 5. That mental stimuli had a considerable effect in one experiment, but in others none at all. These results accord in some respects with those obtained by Schiff in his experiments on dogs, though differing from them in others. This physiologist observed that mastication alone had little or no stimulating action on the parotid secretion in dogs; and Dr. Brunton informs me that he has found this to be the case also in rabbits, while in the experiments above described the action was very distinct. The effect of the application of sugar and tartaric acid to the tongue of dogs was the same as that observed by me. The slight effect of purely mental stimuli in this case is remarkable, as the

parotid is stated by Kühne to be readily affected by them, but this may have been due in great measure to the character of the patient, who seemed to be dull and unimaginative. An experiment was also made for the purpose of determining the time required for the absorption of drugs and their excretion by the saliva. For this purpose iodide of potassium was administered, and the saliva constantly tested till it appeared. The time which elapsed between its administration by the mouth and its appearance in the saliva from the parotid duct was found in one experiment to be 29 minutes and 30 seconds.

Cause of Sleep.—Obersteiner (*Archiv für Psychiatrie*, Bd. 29) considers the proximate cause of sleep to be the accumulation of acid products in the brain, just as in the case of muscular fatigue. The periodicity is merely a matter of custom, like many other bodily functions. All conditions which interfere with the conveyance from the brain of acid combustion-products tend to induce sleep, and all conditions which favor their removal have a contrary effect. The conditions lie chiefly in the state of the circulation. Active hyperæmia in this way prevents sleep. Passive hyperæmia or venous congestion has an opposite effect. Anæmia, by diminishing the activity of interchange between the blood and tissues, favors sleep. Changes in the chemical constitution of the blood, as by narcotics, interfere with the absorption and excretion of the acid products, and hence cause sleep. He compares the cerebral vessels to the bronchial vessels, destined only to nourish the tissue. The real initiative to cerebral action proceeds from the nervous system itself. Hence, to allow of rest from the ordinary association-links of cerebral action, the brain must be disconnected from outward stimuli. When this is done, a tendency to sleep ensues; so also if one impression is kept up long. The continuance of an impression is equivalent to none at all. The will acts as a sort of inhibitory centre to the reflex cerebration. In sleep this is at rest; and hence cerebration shapes itself into dreams. These may be conditioned by stimuli which are not of sufficient intensity to rise into consciousness.

Poisoning by Acetate of Baryta.—In *L'Union Médicale*, M. Lagarde, of Verdun, describes in detail a case of death from the acetate of baryta, and the grave symptoms that he himself experienced from swallowing several grammes of the potion. The doctor had prescribed thirty grammes of the sulpho-vinate of soda for a rheumatic patient. One hour after having taken about a third of the dose, the patient was pale, the features were pinched, the skin was cold, the power of speech was abolished, the respiration was imperfect, voluntary movement was impossible; there was a disgusting taste in the mouth. M. Lagarde tasted the potion, and perceived that a mistake had occurred. The patient having vomited a good deal, the doctor directed his attention to the application of heat. Death soon occurred. M. Lagarde, who had forgotten the draught that he had tasted in order to tranquillize the patient, was taken with serious symptoms three or four hours afterwards,—paleness of the face, and paralysis successively of the arms, legs, muscles of respiration, sphincters of the bladder and rectum; the intelligence was preserved. M. Lagarde thought himself dying, but the symptoms subsided, and eventually disappeared; for a month, however, the doctor, who had become much emaciated, was weak and suffering.

According to M. Wurtz, the salts of baryta are dangerous not so much by the local irritation they produce, as by the action they exercise upon the nerve-centres, and particularly upon the spinal cord.

The Topography of the Ureters in the Female (H. von Luschka: *Arch. f. Gynäkologie*, iii. 373–380: quoted from the *Centralblatt f. die Med. Wiss.*, No. 41, 1872).—The average length of the female ureter is 26 centimetres, and its thickness about 5 millimetres (—$\frac{1}{6}$ in.). The abdominal portion gains a diagnostic importance, since, in cases of excessive retroflexion of the uterus, it is of practical interest that this portion of the ureter on the left side may, from its situation, communicate, by ulceration and adhesion, with that part of the sigmoid flexure which inclines towards the rectum.

That part of the ureter which passes through the inferior pelvis pursues a very oblique course, from behind forwards and from without inwards. The relations sustained by this part of the ureter to the uterus are very important as well as varying, from the physiological mobility of the latter organ. More frequently the uterus inclines towards the right ureter, since the rectum obliges it to assume that position. Beneath the peritoneal limits, the ureters run through the peri-uterine connective tissue, and subsequently cross the lateral end of the base of the broad ligaments. The assertion that the ureters descend through Douglas's space to the fundus of the pelvis is incorrect, according to Luschka. After crossing the round ligament and passing under the hypogastric artery, both ureters reach the supravaginal portion of the cervix uteri.

In the region of the fundus of the vagina, the ureters are only about one-fourth of an inch from the vagina, and finally touch its anterior wall for a distance of $1\frac{1}{2}$ centimetres (half an inch). With the exception of this locality, the ureters are separated from the genital organs by connective tissue and venous plexuses. These relations are especially important for "the where" and "the how" in cases of uretero-vaginal fistulæ.

Suppression of Perspiration (*Centralblatt*, No. 44, 1872).—Socoloff gives an abstract of the results which follow varnishing of the skin and suppression of the cutaneous secretion:

1. A few hours before the death of the animals so treated, clonic and tetanic spasms appear in various groups of muscles, while the temperature in the rectum sinks in a marked degree.

2. Enveloping the animals in wadding did not serve to raise the temperature or to arrest the fatal result.

3. Respiration of oxygen proved ineffectual to resuscitate the animals.

4. In the stomach ulcers were observed, the result of deep extravasations.

5. Albumen appeared in the urine very soon after the skin was varnished.

6. In all cases a diffuse parenchymatous inflammation of the kidneys was observed,—sometimes swelling of the cells, and sometimes fatty degeneration. This result was independent of the nature of the varnish used, whether turpentine varnish, gelatine, or gum.

Lang (*Arch. der Heilkunde*, 1872) investigates the cause of death when the skin has been varnished. In addition to other phenomena, he found an hour or two after death "triple phosphate" crystals in various parts of the body, and some of the uriniferous tubules blocked with a finely granular dark mass. He thinks that the triple phosphate crystals are the result of decomposition of urea, and that the cause of death is uræmia.

Variations in Women's Milk resulting from Insufficient Food (*London Lancet*, Sept. 1872).—Dr. Decaisne lately reported to the Académie des Sciences the results of his observations on forty-three women who suckled their infants on insufficient food during the siege of Paris. Such women either produced abundant and good milk and their children throve, whilst they themselves became greatly emaciated, or they produced but little milk and that of a bad quality, so that the children throve badly, and for

the most part suffered from choleraic diarrhœa; or, lastly, they produced scarcely any milk, and the children died. The following table shows analyses from the three various types:

		Butter.	Casein.	Albumen.	Salts.	Sugar.
1.	Fasting	3.10	0.24	2.20	0.20	6.24
	Well fed	4.16	1.05	1.15	0.30	7.12
2.	Fasting	2.90	0.18	1.95	0.16	7.05
	Well fed	5.42	1.15	0.95	0.25	7.05
3.	Fasting	2.95	0.31	2.35	0.31	5.90
	Well fed	4.10	1.90	1.75	0.31	5.95

It is interesting to notice that the albumen and casein taken together are nearly the same both in the fasting and the well-fed state, though they seem to have an inverse relation to each other.

Treatment of Anthrax by Subcutaneous Aspiration (*Le Mouvement Médical*, January 4, 1873).—We believe that the most effective treatment of anthrax is by crucial incision. Anthrax may also be opened subcutaneously (J. Guérin); an operation which has the advantage of being less painful than the preceding. For timid patients the following treatment may be of service: The canula of a hypodermic syringe is introduced into the centre of the tumor, and pus, if any be present, will rise on drawing the piston. The syringe is detached and emptied, leaving the canula in the tumor; it is then readjusted to the canula, and the piston drawn so long as pus continues to rise; when the pus is completely evacuated, the canula is taken out, and the following preparation is applied to the tumor:

℞ Collodion, 4 grammes,
Castor oil, gtt. xx,
Phenic acid, ogr. 25,
Tannin, 1 gr. 30.

The applications are to be made until a sufficiently thick layer is obtained.

Rupture of the Uterus. (*Le Mouvement Médical*, December 21, 1872: by De Soyre).—The case is that of a woman with a slightly contracted pelvis, and pregnant for the second time. When the head became engaged, a spontaneous rupture occurred immediately above the cervix, measuring five or six centimetres. Flooding ensued, and the patient died suddenly. According to MM. Chantreuil, Cornil, and Lucas-Championnière, there is, probably, in cases of rupture, a degeneration of the muscular fibres of the uterus. M. Chassaignac recalls some researches that he made in conjunction with Dezeimeris, pointing to a friability of the uterine fibres as a frequent cause of rupture. Another cause, entirely mechanical, is when the uterus is compressed against the prominent upper border of the pubes.

La Déformation Toulousaine.—Under this title M. Paul Broca describes (*Bull. de la Soc. d'Anthropologie*, 1872, and *Journal of Anatomy and Physiology*, Nov. 1872) a deformity of the skull met with in the people of Toulouse and its vicinity. It was originally carefully studied by M. Gosse, who showed how it was produced by bandages applied to the head in infancy. Broca's observations are of value in showing the modifications which take place in the shape of the brain in these deformed skulls.

MISCELLANY.

Horse-Flesh as Food.—*The Clinic* of December 28 quotes from the *Allgem. Militär-ärztl. Zeitung* of November 24 the following:

"It has long been known in Germany that horse-flesh was perfectly wholesome, and numerous scientific writings exist which prove that this meat has long been a staple article of diet among certain peoples, as it is even now in certain parts of Germany. The distinguished military surgeon Larrey, and the no less distinguished Geoffroy Saint-Hilaire (recently dead), have written papers on this subject in the interest of the poor. Decroix, a skilful and most industrious veterinary surgeon, has taken up the idea anew with characteristic zeal. De Quatrefages, member of the Academy of Sciences, has lent it also his support in the name of the Society for the Protection of Animals. This society has shown the great value of horse-flesh in the later years of the life of the horse, after it has become incapable of work, when it has not been subjected to cruel treatment or insufficient nutrition. This has led owners to spare their horses, and has enabled them to sell them to advantage after their capacity for labor is over.

"The sanitary councils of Paris and of several of the provinces permitted the erection of slaughter-houses for the preparation of horse-flesh, and this meat, being only half as dear as beef, found many purchasers. The use of horse-flesh did not meet with extensive employment, however, until the siege of Paris, under the urgent necessities which then existed. This necessity it was which quickly overcame all prejudices existing up to that time. From this time on, the value of horse-meat was accepted without dispute, as it has been long ago established in science and was now evident in the personal experience of every one.

"It was found that the mare always furnished the best meat; next in value ranked the gelding. The stallions were of least value. The flesh of the healthy horse was always better and more edible than that of old, lean, or sick animals. Other things being equal, the flesh of the healthy horse furnished a meat containing ten per cent. more nutritious matter than that of the ox."

Fig-Leaves (*Boston Medical and Surgical Journal*).—According to the *Lancet*, there may be observed in the Indian collection at the International Exhibition, in a case of personal ornaments placed against the wall near the southeastern angle of the court, a pair of silver leaves exactly copied from the oval leaves of the Indian fig-tree. In the same and in other cases will be found a variety of metal ornaments of the conventional heart shape, and others of the ecclesiastical piscina, attached to some form of cincture or girdle. All these variations of the leaf-form are used by the Hindoo girls to cover the vulva, and not seldom as their sole article of attire; while the heart and piscina forms are merely conventional copies of the original. This relation between the conventional heart shape and the female sexual organs possibly explains the first use of the former as a symbol of love; and it may also be assumed that the piscina was a heathen emblem, a relic of the phallic worship of some far-back Aryan stock, before it was adopted as a Christian one. The young ladies who purchase valentines, and the architects who copy mediæval decora-

tions, have been about equally ignorant of the meaning of the forms they have assisted to perpetuate.

The modern jewelry collection contains also objects of sanitary interest, in the shape of the thumb-rings, furnished with mirrors, which are worn by Hindoo women. These rings are used for the examination of the genitals, in order to be sure that they are cleansed effectually.

MEDICAL RESPONSIBILITY.—*Le Mouvement Médicale* of December 21 says, "The court of Riom gave, on the 3d instant, an opinion of great importance concerning the principle of medical responsibility. M. Ambroise Tardieu sustained, by a fall, a fracture of one of the bones of the fore-arm. Dr. P. was immediately called in to attend the patient. He applied a dressing which, by its great compression and mal-application, soon caused excessive pain. In spite of the sufferings and complaints of the patient, the physician for five days refused to loosen the dressing, and it was only on the demands of an interne of one of the Paris hospitals, a brother of the patient, who had hastened to him when he heard of the accident, that Dr. P. concluded to remove it. But it was too late. Gangrene from compression was observed, and symptoms of the gravest kind followed. For a long time the physicians summoned to take the place of Dr. P., who had discontinued his visits, feared that amputation would become necessary. They succeeded in avoiding it by careful attention; but from the loss of motion and sensibility the usefulness of the arm was destroyed. The civil court of Clermont, before which Dr. P. was arraigned, after hearing the testimony of physicians summoned to describe the character and the consequences of the treatment instituted by Dr. P., entered judgment, declaring the latter responsible for the accidents following his malpractice and his imprudence, and sentenced him to pay four thousand francs damages.

"Dr. P. appealed from this judgment. But the court, after hearing the pleading of M. Nony for Dr. P. and of M. Vernet for M. A. Tardieu, confirmed the judgment already given."

CHANGES IN THE PARIS HOSPITALS.—In consequence of the death of M. A. Richard, the retiring of M. Giraldès and M. Marjolin, and the transference of Professor Verneuil to the chair of clinical surgery of the Pitié, the following changes have occurred in the surgical service: M. Le Fort goes from the Lariboisière to the Beaujon, M. Panas from the Saint-Louis to the Lariboisière, M. Tillaux from the Saint-Louis to the Lariboisière, M. Péan from the Saint-Antoine to the Saint-Louis, M. de Saint-Germaine from the Saint-Antoine to the Hôpital des Enfants Malades. M. Marc Sée goes from the Midi to the Sainte-Eugénie, M. E. Cruvelhier from the Salpêtrière to the Saint-Louis. M. Duplay leaves the Lourcine for the Saint-Antoine. M. B. Anger goes from the Maternité to the Saint-Antoine, M. Meunier from the Bicêtre to the Salpêtrière. M. Horteloup, Surgeon of the Central Bureau, is stationed at the Midi. M. Lannelongue, Surgeon of the Central Bureau, is stationed at the Bicêtre. M. Dubreuil, Surgeon of the Central Bureau, is stationed at the Lourcine. M. Polaillon, Surgeon of the Central Bureau, is stationed at the Maternité.

MILITARY MEDICAL APPOINTMENTS.—By official order, the following appointments have been made to the commission designed to arrange the reorganization of the Military Health Service: MM. de Martimprey, General of Division; Uhrich, Intendant-General Inspector; Blot, General of Brigade; Blaisot, Military Comptroller; Laveran, Medical Inspector, Director of the School of Military Medicine; Perier and Marit, Medical Inspectors; Devèze, Colonel of Engineers; Gaffiot, Sub-Comptroller of 1st class; Brault, Medical Principal of 1st class; Pierron, Officer of Administration, Secretary. Total, 12.

In discussing medical questions the physicians and apothecaries are in the minority.

"*Plus ça change, plus c'est la même chose!*" is the editor's comment.

THROWING COLD WATER ON IT.—The *British Medical Journal* says that at a recent meeting of the Clinical Society, Mr. Campbell De Morgan in the chair, an interesting communication on the treatment of cases of pyrexia of phthisis by cool baths was read by Dr. C. Theodore Williams, and led to a considerable amount of discussion. The President made some pertinent remarks regarding the present use of cold water in the treatment of pyrexia. He alluded to the period when it was first recommended and carried out by Dr. Currie; and, as an example of the disbelief in its value entertained by the profession in the early part of this century, and their behavior towards the advocates of the cold-water treatment, he quoted the following lines on Dr. K., a disciple of Currie's, from the pen of the late Mr. H. Chudleigh Standert, of Taunton:

"The solid rock the Hebrew smote,
Amidst the desert wild;
The bounteous waters issued forth,
And all the desert smiled.

"His stolid head our prophet smote,
As rugged and as wild;
The water-system issued forth,
And all the doctors smiled."

TRAFFIC IN DIPLOMAS.—The following letter, with an accompanying circular, has been received by the editor of the *Dental Cosmos* from a Parisian dentist to whom it was sent:

[Translation.]

"JERSEY, ENGLAND, October 30, 1872.

"SIR,—As in your profession it ought to be very useful and advantageous to you to have the title of Doctor in Dental Surgery, and to possess the diploma thereto belonging, I have the honor to inform you that I have it in my power to have you dignified as such by the American University of Philadelphia, whose rules and regulations I remit you. I undertake all the formalities at my expenses, risks, and perils; thus you will obtain your diploma without inconveniencing yourself. The total sum of expenses will amount to six hundred francs; after that there will be nothing more to pay.

I am at your service to be useful and agreeable to you, and I pray you to accept my most sincere regards.

"P. F. A. Van der Vyver,

"46 Rue du Roi (*i.e.* 46 King Street.)"

Disgraceful Conduct of Medical Students.—A Montreal correspondent of the Toronto *Globe* says, "The medical students at Victoria College, Montreal, are becoming the disgrace of the city, and are reported to be completely beyond the control of the professors. A few days ago a party of them stole a body from their own dissecting-room, took it to McGill Medical College, received their price, and had a drunken spree on the proceeds. Since then they have been accused of stealing, in broad daylight, a corpse from the Hôtel-Dieu, their own hospital, only dead a few hours, and unburied, of taking it to a college and selling it, and spending the money in a similar way."

Preparatory School of Medicine of Bordeaux. —*Le Mouvement Médicale*, December 21, quotes from the *Bordeaux Médicale* as follows: "In our last number we gave the number of matriculations at the School of Lyons. Those of the School of Bordeaux are as follows: For 1871–72, 286; for 1872–73, 325. We conclude from this that the prosperity of the School of Medicine of Bordeaux now surpasses that of its rival of Lyons."

The following curious advertisement appeared in one of the Cincinnati papers the other day: "Personal.—Wanted—The undersigned, a healthy young man, unable to procure other employment at which he can make an honest living, desires to inform Professors of Medicine and Surgery that he will submit himself to experimental operations of almost any description, for reasonable compensation. Address Vivisection."

Suicides in England.—Suicides are reported to have increased in England, in the last six years, from an annual average of sixty-six to every million of population, to an annual average of nearly sixty-eight to the million. The annual average of suicide by drowning has increased; that by hanging has diminished.

Dr. Halleck was recently appointed Chief Physician of the Insane Asylum, Ward's Island, with instructions to examine into its condition, and report the changes necessary for its efficient management.

Mortality of Philadelphia.—The interments reported at the Health Office for the week ending Jan. 25, 1873, were 356: 197 adults, and 159 minors. 13 were of bodies brought from the country; making the mortality of the city 343. Among the causes of death were:

Consumption of the Lungs	44
Other Diseases of the Respiratory Organs	68
Diseases of the Circulatory Apparatus	19
Diseases of the Brain and Nervous System	56
Diseases of the Digestive Apparatus	23
Zymotic Diseases (one from Smallpox)	27
Typhoid Fever	8
Casualties	7
Cancer	6
Debility (including "Inanition" and "Marasmus")	42
Still-born	20
Old Age	10

(The interments reported for the week ending Jan. 27, 1872, were 490.)

The meteorological record kept at the Pennsylvania Hospital was as follows:

	Thermometer. Max.	Thermometer. Min.	Barometer. (2 P.M.)
Jan. 19	26.0°	20.0°	30.18 in.
" 20	36.0	21.0	30.14 in. (Rain.)
" 21	40.0	32.5	29.83 in.
" 22	37.5	35.0	30.16 in.
" 23	35.0	29.0	30.20 in. (Snow.)
" 24	55.5	29.5	29.76 in. (Rain and snow.)
" 25	33.0	21.0	30.22 in.

OFFICIAL LIST

OF CHANGES OF STATIONS AND DUTIES OF OFFICERS OF THE MEDICAL DEPARTMENT U.S. ARMY, FROM JANUARY 14, 1873, TO JANUARY 20, 1873, INCLUSIVE.

Girard, A. C., Assistant-Surgeon.—To report by letter to the Commanding General, Department of the South, for assignment to duty, S. O. 12, War Department, A. G. O., January 15, 1873.

Weisel, Daniel. Assistant-Surgeon.—To report by letter to the Commanding General, Department of the South, for assignment to duty. S. O. 12, c. s., War Department.

NAVY NEWS.

LIST OF CHANGES IN THE MEDICAL CORPS OF THE NAVY, FROM DECEMBER 12, 1872.

Assistant-Surgeon C. A. Siegfried,—To U.S.S. Richmond.

Assistant-Surgeon J. M. R. Simmons,—Died at Naval Hospital, Phila.

Assistant-Surgeon Wm. A. Couvin,—To the Naval Hospital, Chelsea, Mass.

Assistant-Surgeon George O. Allen,—To the Receiving Ship Ohio, Boston, Mass.

Surgeon M Bradley,—Detached from Naval Station, Mound City, Illinois, and to Navy Yard, New York.

P. A. Surgeon F. M. Dearborne,—To U.S.S. Supply.

A. A. Surgeon J. W. Elston,—To Naval Station, Mound City, Illinois.

P. A. Surgeon D. Dickinson,—To the Naval Hospital, Yokohama, Japan.

P. A. Surgeon H. M. Rundlett,—Waiting orders.

Medical Director George Maulsby,—Retired.

Assistant-Surgeon E. C. Thatcher,—Sick leave.

Assistant-Surgeon W. B. Davis,—To U.S.S. Saugus.

Assistant-Surgeon P. P. Bieley,—Waiting orders.

Assistant-Surgeon H. M. Martin,—To Navy Yard, Washington, D.C.

Surgeon A. C. Rhoades,—To U.S.S. Guard.

Surgeon J. S. Knight,—To Receiving Ship Ohio, Boston, Mass.

Assistant-Surgeon William G. Farewell,—Leave of absence.

The Naval Medical Board for the examination of candidates for admission and promotion in the Medical Staff of the Navy has reconvened at Washington, with the following detail:

Medical Director William Grier, President.

Medical Inspector Thomas J. Turner, Medical Inspector John Y. Taylor, Medical Inspector Albert L. Gihon, Members; and Surgeon Philip S. Wales, Recorder.

[About twenty-five vacancies exist in the grade of Assistant-Surgeon.]

SATURDAY, FEBRUARY 8, 1873.

LECTURES

ON THE SURGERY OF THE NARES, LARYNX, AND TRACHEA.

BEING THE MÜTTER LECTURES FOR 1872.

Delivered before the College of Physicians of Philadelphia,

BY J. SOLIS COHEN, M.D.

Reported by R. M. BERTOLET, M.D.

(Continued from page 274.)

LECTURE II.

EXAMINATION OF THE LARYNGEAL IMAGE IN DETAIL.

HAVING in the preceding lecture considered the different methods employed in making laryngoscopic or rhinoscopic examinations, it remains for us to study the images of these parts as seen in the healthy state, before going to the consideration of morbid conditions and changes occurring in them.

We must content ourselves with referring the reader to any of the more extensive treatises upon anatomy for a detailed description of these parts; that of either Henle or Luschka will be found very complete so far as relates to the anatomy of the larynx.

The most conspicuous structure attracting attention in the laryngeal image is the epiglottis, whose free portion, jutting upwards from the base of the tongue, renders it easily recognized. Directing our attention to this cartilage, we perceive an anterior and a posterior surface, and an upper arching crest, frequently indented; from its lateral borders is given off on either side a pharyngo-epiglottic fold of mucous membrane, arching upwards and forwards to join the posterior palatine arch as it terminates in the lateral pharyngeal wall. As this fold leaves the epiglottis, we distinguish another and thicker fold, leaving the same point at nearly right angles, and stretching curvilinearly backwards to the arytenoid cartilages. This is the ary-epiglottic fold forming the superior free border of the quadrangular membrane of the larynx. The anterior or lingual surface of the epiglottis is seen to be slightly concave from above downwards, and strongly convex from side to side, while its posterior surface is concave and convex in the opposite directions. Upon observing the posterior or laryngeal surface of the epiglottis, we notice that it swells out abruptly into a considerable belly or pad, which tapers down to its point of attachment.

This tubercle or pad of the epiglottis, also known as the "cushion of the epiglottis," is formed chiefly by an aggregation of mucous glands and adipose tissue. It very often projects sufficiently to cut off the view of the anterior portions of the vocal cords attached to the intermediate plate of the thyroid cartilage below. The normal color of the pad is quite red; and by artificial illumination it will have a deeper color than by sunlight, a point to be borne in mind, lest the diagnosis of congestion be improperly made. Stretching from the middle line of the lingual surface of the epiglottis to the raphé of the tongue is seen the median glosso-epiglottic fold or frænulum of the epiglottis. It is a small, sharp-edged membranous fold, enclosing the glosso-epiglottic ligament, and serves to force the epiglottis to participate in the movements of the tongue. Upon each side of this fold, which is strongly raised when the tongue is protruded, there is seen an indentation, sometimes shallow, often deeply depressed. These are the *lingual sinuses*, termed the glosso-epiglottic fossæ or sinuses by some,—the valleculæ by others. When shallow, they gradually become lost in the lateral border of the tongue; but more frequently they are strongly depressed at the frænal outline, and, becoming less deeply marked on either side, are bounded exteriorly by a sharp fold of the mucous membrane of the sides of the tongue, called the lateral glosso-epiglottic fold. These lateral folds do not enclose any ligament, and, though generally found to exist post-mortem, are very frequently absent in the living organ. In the floor of these sinuses we are able sometimes to discern with the laryngoscope the position of the greater horn of the hyoid bone, which appears as a clear, longish-oval projection behind and extending outwards. These lingual sinuses often afford lodgment for articles of food and various foreign bodies, and they are not unfrequently the site of morbid processes, especially of tuberculous, scrofulous, or syphilitic ulcerations; cystic growths have also been seen in them. We have devoted considerable space to the apparently unimportant lingual surface of the epiglottis, but the importance of always examining it cannot be over-estimated, as there are a number of cases on record in which long-continued throat-disease had resisted topical applications to the larynx,—diseases which the laryngoscope revealed to be ulceration of these sinuses, soon healed by proper local treatment.

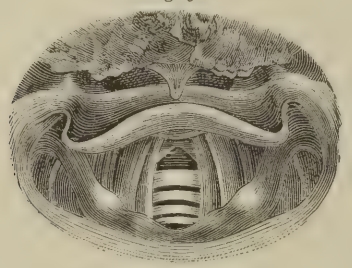
The color of the epiglottis is a light red, veiling a yellowish white, being less pronounced at its edge, where the color of the cartilage is more distinct,—much like the color of the conjunctival membrane of the eyelid, to which it was compared by Störk. Posteriorly the red deepens. The thickness of the epiglottis varies from a sharp thin edge—hardly a line—to a thick stump of several lines; and, when swollen, it may be as thick as a finger. It is also very variable in shape: sometimes it is long, narrow, and pointed; sometimes the sides roll in together posteriorly until they nearly touch; sometimes it is curled inwards with a contraction in the middle, which has been called the Omega-shaped epiglottis. This latter condition is either congenital or acquired by the contraction of cicatricial tissues. Ordinarily the epiglottis will be found to overlook the laryngeal entrance at an angle of from forty to sixty degrees; but it is sometimes depressed backwards much more, so that it may entirely cut off the view into the larynx.

Outside the ary-epiglottic fold, between it and the inner face of the thyroid, we see the triangular *pyramidal sinus*, which begins on each side of the free border of the epiglottis as a small, dark, deep

fossa, becoming more and more conical as it descends, until it is finally lost at one end of the transverse furrow marking the commencement of the œsophagus. The outer wall is formed by the inner face of the wing of the thyroid cartilage, and above this is the hyo thyroid membrane and then the hyoid bone; on the inner side is the quadrangular membrane, which forms a vertical angle anteriorly with the wing of the thyroid; and behind, it is bounded by the posterior wall of the pharynx. It is lined by the common pharyngeal mucous membrane, and along its angular floor there is a chain of glands often involved in disease of these parts. These pyramidal sinuses are sometimes entirely empty; sometimes they contain mucus, and sometimes a sort of cheesy deposit; they often afford a lodgment for foreign bodies, and they are frequently involved in pharyngeal troubles.

When the tongue is protruded and the epiglottis well raised (Fig. 5), we gain a view of the whole

Fig. 5.



The Laryngoscopic Image.

circumference of the superior laryngeal aperture. It is of a cordiform shape, wider in front than behind, sloping obliquely downwards, and terminating behind in the vertical inter-arytenoidal fissure. Its border in front is the free rim of the epiglottis; then, on either side, the ary-epiglottic fold, which arches backwards in the form of a bow until it reaches its arytenoidal attachment posteriorly, where it surrounds the rounded eminence of the cartilage of Santorini; and the two arytenoids, with their connecting muscle and mucous fold, complete the border posteriorly. The ary-epiglottic fold is divided into two unequal festoons by a swelling, in front of the Santorinian cartilage, enclosing the staff-like cartilage of Wrisberg, surrounded with glands and adipose tissue. The color of the ary-epiglottic folds has been well compared by Störk to that of the gums. The eminences of Wrisberg and Santorini are of a rather lighter color than the rest of the mucous membrane.

About half an inch below the superior aperture of the larynx are seen the *ventricular bands*, often still improperly designated as false vocal cords. They appear as broad mucous folds of a red color, and are formed by the mucous lining of the larynx folding under on itself, and leaving between it and the upper surface of the vocal cord of the same size—seen immediately below as a white, glistening band extending from before backwards—an oblong interval, which is the entrance into the Morgagnian ventricle of the larynx. By means of a deep inspiration, especially if short, sudden, and following vocalization, these ventricles can be rendered more distinct, and a separation of their walls be observed dilating the cavity. The size of the ventricles, or rather the space constituting them, varies. The mucous membrane lining the laryngeal sacs is thickly studded with the openings of numerous follicular glands, situated in the sub-mucous connective tissue. The laryngeal surface of the sac is covered by the inferior portion of the arytenoepiglottideus muscle (*compressor sacculi laryngis* of Hilton), which compresses it and discharges its secretion upon the true vocal cords, which, being themselves unprovided with glands, are thus lubricated.

The healthy *vocal cords* are easily recognized by their rapid movements during vocalization, and by their striking white, semi-metallic lustre,—at times a mother-of-pearly white in the female. When the two vocal cords are approximated in phonation, the entire breadth of the horizontal surface, forming the floor of the upper laryngeal cavity, is brought to view. The chink or fissure between the free margins of the vocal cords constitutes the *rima glottidis*. Its length varies from ten to thirteen lines, being longer in the male than in the female; in children it is much shorter; and, when fully dilated by a deep inspiration, the space across will vary from six to ten lines. Each cord consists of a compact band of parallel fibres of the thyro-arytenoid muscle, of elastic and fibrous tissue, arranged in prismatic form, the base pointing outwards, so that a vertical section shows the upper surface horizontal, and the lower surface taking an oblique direction downwards and outwards.

The posterior points of insertion of the vocal cords are seen with good illumination as yellowish spots,—the *maculæ flavæ*, which mark the position of the vocal processes of the arytenoids.

When the epiglottis is well erected, as by the emission of a high musical note, so that the anterior parts of the vocal cords can be discerned, we see beneath the small end of the pad of the epiglottis, immediately below the junction of that cartilage to the thyroid, and separating the anterior attachments of the ventricular bands, a well-marked, pinhead-like pit or foramen (*fovea centralis* of Merkel) in the mucous membrane. This fovea centralis communicates directly on both sides with the anterior entrance into each Morgagnian ventricle, being continuous below with a shallow groove formed by a short fold of the laryngeal mucous membrane, which stretches across from the anterior end of one vocal cord to the other. It is very small in the human subject, but quite large in some of the lower animals; in the horse it seems to constitute a middle ventricle to the larynx.

As already mentioned, the form of the rima glottidis varies. During ordinary respiration it is a narrow lozenge-shaped interval, somewhat enlarged and rounded behind. When fully dilated, the rima assumes the form of an isosceles triangle, with the base behind. The form of the rima varies greatly during phonation, and may become elliptical, oval, or only opened anteriorly or posteriorly, as the

cords are contracted in different degrees by the complex laryngeal muscles in the production of the various vocal sounds. In the formation of the head-notes, the arytenoid cartilages are observed to come together, and only the anterior or ligamentous portion of the rima is seen to gape. In the formation of the chest-notes, the entire cord is seen to vibrate; but in the production of the falsetto notes the vibrations of the cord are limited to the free margin of its membranous portion.

The mucous membrane, extending from one arytenoid cartilage to the other, is more or less plicated, and is known as the *commissure* of the arytenoids. It is best examined when the arytenoids are widely separated, and is one of the most frequent sites of ulceration in connection with phthisis.

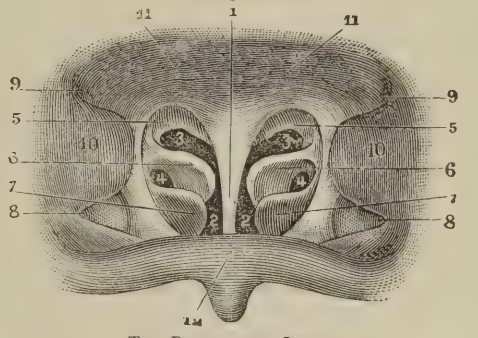
Below the vocal cords appears the broad yellow cricoid cartilage, and below it again the rings of the trachea are seen elevating the mucous membrane. To obtain an extended view down the trachea, the mirror must be held more perpendicularly, and a deep inspiration made, so as to open the glottis to its fullest extent, and then, by a little manipulation reflecting the light more anteriorly, we are enabled to see the tracheal rings as narrow bands, colored like the conjunctival membrane of the eyelid, arching across with their concavities downwards, becoming narrower and closer as they are more distant, until the foreshortening is such that they cannot be distinctly counted; and sometimes in this way, when the circumstances are favorable, such as a wide glottis, good light, straight trachea, etc., we obtain a view clear down to the bifurcation of the tube.

In examining the trachea, it is a good rule to elevate the position of the patient so that the eye of the observer shall be below the plane of the patient's mouth; then throwing the light from below upon the laryngoscopic mirror, which must be held horizontally, the light can be reflected clear down the tube; and if the bifurcation be visible, we see behind the last ring (below in the mirror), instead of the complete arch with its concavity downwards, a bright triangular ridge, which often seems to project up into the cavity of the tube, and on either side of this bright projecting line dark disks marking the commencement of the bronchi. In a few cases, where the right bronchus is very straight, a ray of light may be so thrown in as to show several of its rings.

STRUCTURES SEEN IN THE RHINOSCOPIC IMAGE.

The most prominent and easily recognized object in the rhinoscopic image (Fig. 6) will be found to be a bright columnar ridge in the middle, gradually expanding upwards. This is formed by the nasal septum, and has in health a pale yellow or almost white color at its lower portion, but as it expands its color gradually merges into the bright red of the mucous membrane of the pharyngeal vault. The lowermost portion of each nasal opening is generally more or less cut off from view by a horizontally-curved projecting ridge, which is formed by the rising up of the posterior surface of the velum; and thus it often becomes impossible to inspect the inferior meatus just beneath the lower turbinated bone. Projecting from the outer wall of the nares on each side, and extending inwards and downwards to within a few lines of the septum, are seen the middle turbinated bones, covered with a gray-

Fig. 6.



THE RHINOSCOPIC IMAGE.

1, septum of the nose; 2, free space of nasal passage; 3, superior meatus; 4, middle meatus; 5, superior turbinated bone; 6, middle do.; 7, inferior do.; 8, pharyngeal outlet of Eustachian tube; 9, upper portion of Rosenmüller's fossa; 10, lateral wall of pharynx; 11, vault of pharynx; 12, posterior surface of velum.

colored mucous membrane: the free end towards the septum, being very wide, lends to the middle turbinated bone a very deceptive resemblance to a polypus. The superior turbinated bone, above the upper meatus, and still within the passage, is seen as a narrow triangular projection of a light pink color.

At the base of the nasal fossæ, the inferior turbinated bones, partially covering the middle ones, are seen as round dark-grayish-looking projections; above them and to the outside will be observed a dark fissure,—the middle meatus.

Upon each side of the lateral walls of the pharynx, on a plane with the inferior turbinated bone, is seen a projecting ridge, which is the cartilaginous extremity of the Eustachian tube; and in it we observe a triangular depression, which is the pharyngeal orifice of that tube. Behind the protuberance caused by the Eustachian tube and the posterior wall of the pharynx is seen a deep canal running upwards and outwards; this is the fossa of Rosenmüller, and is the point in which the Eustachian catheter is so often lodged in ineffectual attempts at its introduction.

The vault of the pharynx must not be neglected in the rhinoscopic examination, since its mucous covering, so abundantly supplied with follicular glands, is very apt to be the starting-point of some diseased condition, such as glandular hypertrophy, ulceration, adenomatous growths, etc.

The parts that can be seen with the rhinoscopic mirror may be enumerated as follows: the posterior surface of the soft palate and uvula; the posterior and part of the lateral portions of the nose, the turbinated bones, and nasal meatuses; the pharyngeal walls of the Eustachian tube and its orifice; the vault of the pharynx and its lateral walls; and the upper portion of the posterior wall of the pharynx. All of these structures cannot, however,

be seen in one and the same image; but by slowly turning the mirror towards the different regions we gradually obtain a satisfactory survey of the whole in detail. Under the most favorable circumstances, both posterior outlets, both Eustachian tubes, and part of the pharyngeal vault, are seen in one and the same image.

ORIGINAL COMMUNICATIONS.

ON THE OPERATION OF "PERINEAL SECTION" FOR URETHRAL STRICTURE.

BY JOHN H. PACKARD, M.D.,
Surgeon to the Episcopal Hospital, Philadelphia.

THE word "impermeable," as applied to strictures of the urethra, although perfectly distinct in its meaning, is in practice an extremely vague term. For, apart from all other circumstances, there is one very variable element in the matter, and that is the skill of the surgeon. A stricture in which Sir Henry Thompson would find no great difficulty, might be absolutely impassable by the same instrument in the hands of a gentleman of less experience and dexterity. Hence the word "impermeable" does not, and cannot, indicate a certain class of strictures, but simply expresses the fact, in regard to any one case, that all attempts at the introduction of instruments into the bladder have failed and are likely to fail.

It is well known that very often a stricture, which seems extremely obstinate, yields at once to the catheter if the patient is placed in a state of anæsthesia.

If in any case the surgeon cannot, with all the means and appliances at his command, and with the aid of ether or chloroform, succeed in reaching the bladder, that stricture is to him impermeable, and, if the symptoms are urgent, some other plan must be resorted to. And the question may well be asked whether it is safer for a surgeon who finds great difficulty in a case, to work on with catheters, and run the risk of doing damage in his efforts to find the channel, or to lay this latter open at once, and give his patient the chance of a new formation of a urethra of full size.

It becomes, therefore, an important point to determine how far the cutting operation from without inwards, in these cases, is attended with risk. I propose to relate presently seven cases of my own, in which the ultimate results were wholly satisfactory. But it must first be stated that authors are not agreed upon this point of the safety of the procedure; and that the distinguished surgeon before mentioned, who is generally recognized as the highest authority on the subject of stricture, makes a marked difference between the "external division" and "perineal section." He speaks as follows in his excellent article in Holmes's "System of Surgery" (vol. iv. p. 974): "Mr. Syme has advocated the division of the stricture for some exceptional cases, in which, *although a catheter can be passed into the bladder*, no other treatment has afforded sufficient or permanent relief. This operation he has called 'external division,' a term which should be reserved for his method; while it is equally desirable to limit the use of the term 'perineal section' to the proceeding just referred to in connection with strictures which have been found impervious to the catheter." In the next paragraph he says, "There is a growing belief, which has greatly influenced practice, that few, if any, strictures exist through which, if the urine issues externally, a catheter of appropriate size may not be passed in the course of time, with care, gentleness, and skill." He endorses this opinion, and says that he has only twice found it necessary to perform "perineal section."

Subsequently (p. 977) he says, "In reference to the operation without a guide, or the perineal section, the best that can be said of it is, that it is a hazardous proceeding, and no surgeon should entertain the idea of performing it except after thoroughly assuring himself that the stricture cannot be rendered permeable to instruments, and so made amenable to other modes of treatment. In a few cases the operation is performed successfully, but in most there can be little doubt that the route of the stricture itself is not followed, and that the knife makes a new channel through adjacent and often very unsound tissues, very inadequate to perform subsequently the function of a urethra. In many instances the attempt to make a channel to the bladder has wholly failed, and the patient has been removed from the operating-table unrelieved; and in not a few the result of the proceeding has been fatal. This termination, however, is to be anticipated in a large proportion of what must necessarily be the worst cases of their kind. Such views of this operation tend to impress us more strongly with the conviction, that every chance of getting an instrument through the dilated urethra by protracted but gentle endeavors, combined with rest and constitutional treatment, should be exhausted before we consent to resort to perineal section."

Prof. Gross, after justly speaking of Syme's procedure as a mere modification of the old button-hole (*boutonnière*) operation, and describing it, says ("System of Surgery," 5th ed., vol. ii. p. 823), "In the button-hole operation, as the conductor is not passed into the bladder, but only down to the seat of the obstruction, the amount of skill required is much greater than in the ordinary procedure. Indeed, it should never be undertaken unless the surgeon is thoroughly acquainted with the anatomy of the parts, is perfectly self-possessed, and knows how to use the knife. A number of cases have been reported in which death occurred from hemorrhage, shock, pyæmia, erysipelas, or urinary infiltration."

Sir William Fergusson ("System of Practical Surgery," 5th ed., p. 693) says, "In some instances there is such an amount of local disease and continued irritation that life is hardly worth enduring: in other cases speedy death is impending unless the surgeon interferes, and if he cuts into the perineum in the mesial line, divides the stricture and introduces a full-sized catheter along the whole of the urethra into the bladder, he is resorting to an old established practice of surgery which

can scarcely be sufficiently praised. It confers the greatest relief on the patient, and may justly be called a triumph of surgery. It is a formidable operation, however, and as such is not free from danger. Death sometimes follows, and hence the surgeon is cautious in resorting to it, excepting in extremity."

Other authorities might be cited, but perhaps it is hardly necessary. I believe that the continental writers, the French certainly, are but little in favor of the "perineal section."

One other alternative has been by some authors highly praised for the relief of the condition in question, viz., tapping by the rectum. Mr. Oliver Pemberton, in a recent address before the British Medical Association, advocates this procedure quite warmly. (And here we note another of those unavoidable uncertainties of expression, which may well puzzle a young and inexperienced man. "If," says Mr. Pemberton, "the induration of the urethra, and narrowing, be of such an extent as to preclude the idea of dealing with it by external division, I prefer to tap the bladder by the rectum." How is a man to decide what "such an extent" is, if he has never had practical, and especially hospital, experience in cases of this kind?) Tapping of the bladder through the rectum has never been an operation in much favor in this country; I have never known of its performance in this city.

I propose now to relate my own cases, which are taken from the records of my hospital service, and which seem to me to sustain, so far as they go, the value of the operation of "perineal section." One of them is particularly interesting, since the physiological rest, given to the urethra by the incision, made catheterization, impossible at the time, very easy three weeks afterwards.

Case I.—C. H., a colored coachman, came under my care in July, 1861, suffering from complete retention of urine, due to an old stricture,—not, I believe, of venereal origin. After satisfying myself that I could not introduce any instrument, I sent him to the Pennsylvania Hospital, where "perineal section" was performed by Dr. Hewson. By this operation he obtained temporary relief, but the symptoms all returned, the retention was relieved by the bursting of urinary abscesses, and he finally was admitted under my care at the Episcopal Hospital, in 1865, suffering with stricture, fistulæ of great extent, and difficulty of urination. I divided the stricture by perineal section, and laid open the shorter fistulæ, cauterizing the latter with a hot iron, and passed oakum setons through the longer fistulæ. Healing took place without contraction, by means of the steady use of large instruments; all the fistulæ closed, and he has now been for about seven years wholly free from stricture or any difficulty in urination, notwithstanding the fact that he has of late neglected the use of the bougie.

Case II.—August 4, 1867, I operated on a sailor at the Episcopal Hospital, whose stricture would not yield to any efforts at catheterization on my part. On dividing the tissues in the median line, I was fortunate enough to hit the urethra beyond the narrowed portion, which was freely laid open. The case did well, and the man was discharged entirely relieved. (The exact time of treatment in this, as in most of the other cases, I cannot easily ascertain.) Of course I have lost sight of him since, as is apt to be the case with sailors.

Case III.—R. D., æt. 30, was the subject of a traumatic stricture of seven years' standing, caused by a bank of clay caving in on him and fracturing the pelvis. I performed "perineal section" on him on the 26th of October, 1868, at the Episcopal Hospital. With very great difficulty, a grooved director was inserted into the bladder from the wound, and tied in. On the 31st I succeeded in slipping a small silver catheter along the urethra, and, guided by the director, into the bladder.

November 2, a large-sized double-curved instrument was passed, and tied in.

December 11, the urine is noted to have been passed almost wholly through the catheter for a week.

January 17, 1869, the instrument was removed. Two fistulæ existed, one at the seat of operation, and one at the root of the scrotum, caused by the angulation of the tissues by pressure of the catheter. The former healed spontaneously. The other one was twice sutured, and repeatedly cauterized; it finally closed to a mere pinhole, and he was discharged May 4, passing his urine in a full stream. Two years later he wrote me from the interior of the State that he was quite well, and had married.

Case IV.—C. R., æt. 35, was operated on by me at the Episcopal Hospital, October 12, 1869, for an impassable stricture, by "perineal section." He did well, and was discharged with a urethra of normal calibre.

Case V.—September 30, 1870, I operated on J. L., æt. about 35, at the Episcopal Hospital, for traumatic stricture of several years' standing. After many attempts, I failed to get any instrument into the bladder. The urine came away wholly by the wound. About *three weeks afterwards*, I succeeded in passing a silver catheter of small size along the urethra into the bladder, and left it in place. Larger instruments were afterwards passed, and he was discharged cured.

Case VI.—December 21, 1871, I operated on a man at the Episcopal Hospital, William ——, æt. 30, by "perineal section," for the relief of stricture with fistula. He did perfectly well, and is now employed as an assistant in the house.

Case VII.—A. W., æt. 39, slipped and fell on his belly two years ago. About a week afterwards he had trouble in urinating, and was relieved by means of a catheter. He has never since then been able to pass water freely. An abscess formed some three months later, and others have been forming about every three months since that time. He passes about a teacupful daily through the natural channel; the rest dribbles away through numerous fistulæ in the scrotum and perineum.

December 5, 1872, I performed "perineal section," and after much difficulty got a grooved director from the wound into the bladder, and then a small silver catheter the whole length of the urethra.

December 9.—The catheter was removed and cleaned. From this time until the 31st, the removal and cleansing was done daily; and on the 12th of January, 1873, he was discharged entirely cured, with directions to attend to keeping the urethra dilated.

The above cases are only those which have occurred to myself. I have seen a number of others, some sixteen in all, operated on by other surgeons, with good results. Let me not be understood to maintain that this procedure is one to be lightly undertaken, or free from risk; but I think the favorable experience of it in my own hands, as now recorded, may be allowed some weight. The cases requiring it are certainly among the most urgent which come under surgical care.

1928 Spruce Street, Feb. 1873.

NOTES OF HOSPITAL PRACTICE.

JEFFERSON MEDICAL COLLEGE.

SURGICAL CLINIC OF PROF. S. D. GROSS.

Reported by FRANK WOODBURY.

AMPUTATION OF PART OF THE TONGUE FOR CARCINOMATOUS DISEASE.

UPON looking at this patient (thirty-eight years of age) you see at a glance that he is a sick man; his face is sallow, and his frame is emaciated. He states that since he first began to be sick, nine months ago, he has lost over forty pounds in weight. The quantity of urine voided is normal in quantity and quality. His bowels are open; he has no flatulence, indigestion, nor unusual thirst; his appetite is good, but he cannot eat; his hands and feet are warm; he never had intermittent fever, or night-sweats, but he has a trouble of his tongue, which commenced four weeks ago, in which he experiences constant burning, at times lancinating, pain, which seriously interferes with mastication and deglutition. As he protrudes the tongue, you notice a surface continuously ulcerated, principally on the left side of the median line, extending from the tip a considerable distance back. I can find no enlarged lymphatic glands under the jaw. His diet is necessarily confined to the blandest articles, and such as require no mastication, such as milk, beef-tea, and milk-punch. His face is not pallid or livid exactly, but has a sallow, cadaverous appearance peculiar to the cancerous cachexia.

This may be either of two affections,—syphilis or epithelioma. A man may have a chancre on his lip or tongue by inoculation from a mucous patch, or directly from virus accidentally carried by the finger; or an ulcer may exist here as the result of constitutional syphilis. In such a case, however, the ulcers have well-defined edges, generally with a foul, irregular base, and are not single, but appear in scattered patches; they are not confined to the tongue usually, but co-exist on the fauces, uvula, and pharynx. There would also be evidences of specific disease in other portions of the body, and a distinct history of inoculation, neither of which exists in the present case.

Therefore, by exclusion, and from the appearance, hardness, and peculiar pain, I would consider this epithelial cancer, or cancroid, as it was termed by Prof. Miller, of Edinburgh; or, properly, scirrhus modified by the structure involved. This generally comes without assignable cause. It has been attributed to smoking a short pipe, with the hot stem constantly against the tongue; but this is unsustainable by proof, the disease in some cases occurring in patients who never smoked, while thousands of others escape who are inveterate smokers. Encephaloid disease of the tongue is extremely rare, while colloid and melanosis in this situation are unknown. This disease is most common after the age of fifty, and in the male sex. It commences as a little sore, papule, or crevice, in the tongue; it then gradually spreads and ulcerates, and is the seat of the characteristic pain, which is generally worse at night. The surrounding part is hard, from infiltration of plastic lymph and cancer-cells, and the organ can no longer be used in mastication, on account of its stiffness and the pain produced by moving it. The disease finally extends to the gums, the teeth fall out, the submaxillary glands enlarge, and the system sinks under the exhaustion from the cachexia which becomes established, and from impaired nutrition. The fatal result generally supervenes within a year or eighteen months from the onset of the disease.

The only operation likely to afford any relief would be excision of the affected part, not in the hope of cure, but to palliate the symptoms. But he is not in a condition to bear such interference at present; his general health must first be improved by relieving his pain and allowing him to sleep, by giving him gr. xxx of chloral at night. He shall have plenty of soft, nourishing food, such as milk-punch, animal broths, soft-boiled eggs, etc., with daily open-air exercise, and may wash his mouth frequently with dilute solution of permanganate of potassa. It is important that the patient should not swallow the secretions, as pyæmia might result. I have seen this occur in two cases,—in one after removal of a polypus, and in the other from plugging the posterior nares.

November 20 (one month later).—The patient's health is much improved, and he returns for operation. The ulcer is now rapidly spreading beyond the median line of the tongue, and also on the under surface. Ablation, or excision of the tongue, is not required in this case; removal of the offending part is all that will be attempted. This should not be done with the knife, as there would be severe, perhaps uncontrollable, hemorrhage from the vessels, which are now abnormally increased by the disease. This is one of the operations to which the écraseur is eminently applicable, as it crushes and lacerates the vessels, producing rapid coagulation of the blood and diminishing hemorrhage. Before applying the chain of the instrument, the tongue is transfixed by three stout steel pins at the line where you wish to amputate. The écraseur is then applied and the diseased mass removed. The lingual artery and a few small vessels required the ligature; the capillary oozing was checked by ice. The operation was performed without an anæsthetic, at the patient's request. An anodyne will be given immediately, and the former treatment continued, to which shall be added quinine and iron.

[The patient was subsequently shown at the clinic, and reported himself as being much more comfortable. He made a good recovery from the operation, and there was no secondary hemorrhage. He was then able to speak so as to be understood, although half of the anterior portion of the tongue had been removed transversely. He afterwards complained of a severe sore throat, and within two months from the operation died from debility. No examination could be obtained.]

IMMENSE NÆVUS ON SCALP.

This child (nine months old) is brought before you to exhibit the progress of a nævus maternus without operative interference. This disease, although undoubtedly of congenital origin, yet was then so small that it was not noticed until several weeks after birth. It was then on the scalp, but gradually spread, so that it now extends over the top of the head towards the right side, and involves the entire left side of the scalp, forehead, face, and neck, distorting the ear and almost closing the eye. The tumor is soft, bluish, pulsates, and is apparently painless.

This is the type of a nævoid tumor. It is composed essentially of dilated capillaries, which are abnormally numerous, having a cavernous structure in parts, resembling the erectile tissue of the corpora cavernosa or the spleen. These tumors vary according as the arterial or the venous element predominates in them: where they are both equally represented, it forms the true aneurism by anastomosis of Mr. Bell. Where the venous element is in excess, there is not such great danger of hemorrhage, and the tumor may be removed by the knife, or the spongy structure torn out by the forceps, as has been recommended by my colleague, Prof. Pancoast.* When the arterial character of the

* *Medical Times*, vol. i. p. 288.

tumor is more marked, as is seen by the scarlet color and decided pulsation, then the risk of hemorrhage would be far greater, and strangulation by the ligature would be the safest operation. Other means of treatment have been recommended, as by injecting styptics, but they are uncertain and dangerous. Some surgeons have cured them, when small, by vaccinating over them. Setons, either simple or impregnated with Monsel's solution, have been used effectively; and large tumors may be obliterated by darning them with these threads, which excite inflammation and plastic effusion, thus occluding the vessels.

The disease here is rapidly spreading, and, if not stopped, will soon involve the entire head and shoulder. I would suggest that the largest portion of the tumor be strangulated by the pins and a stout ligature, and the remaining portion be left for a subsequent operation. By undertaking too much at once, we might increase the danger from pyæmia or erysipelas.

If this child were older, or the disease had existed for a long time, we would undoubtedly find in it phleboliths, formed from plasma which had undergone the earthy degeneration.

TRANSLATIONS.

VON OPPOLZER'S LECTURES ON DISEASES OF THE ŒSOPHAGUS.

Being the latter portion of the first part of the second volume of Oppolzer's Vorlesungen über specielle Pathologie und Therapie, Erlangen, 1872.

Condensed from the German of Dr. Emil Ritter von Stoffella,

BY DR. J. SOLIS COHEN.

II.

ŒSOPHAGITIS.

INFLAMMATION of the œsophagus is either catarrhal, croupal, or pustular. It may extend over a large portion of the œsophagus, or be confined to a small portion. It occurs as an idiopathic affection less frequently than as consecutive to some other affection. Besides these three designated forms of inflammation, there is that of ulceration; and, in poisoning with caustic substances, more or less extensive gangrene of the œsophageal mucous membrane.

Acute catarrhal œsophagitis may result, idiopathically, from change of temperature; from the deglutition of very hot or very cold viands, or of irritating or caustic substances, as in moderate degrees of poisoning; from the mechanical irritation of sharp impacted bodies, as bits of bone, etc. It may occur consecutively by extension of gastric catarrh, or catarrh of the mouth and pharynx. It may occur symptomatically in the acute exanthemata, especially in measles and typhus fever.

Chronic catarrhal œsophagitis may follow acute inflammation of the mucous membrane; or it may follow some long-continued or frequently renewed irritation of the œsophageal mucous membrane; or it may follow habitual stasis of the blood in the veins of the œsophagus. It is encountered particularly in inveterate tobacco-smokers, in individuals who indulge immoderately in alcoholic beverages, and in those suffering with some chronic pulmonary or cardiac disease. Syphilis, too, seems to favor the occurrence of a chronic catarrhal affection of the œsophageal mucous membrane.

Croupal inflammation of the œsophageal mucous membrane is a much rarer affection than catarrhal inflammation. Œsophageal croup exists in combination with croup of the pharynx or larynx, or, in certain cases, in connection with croupal pneumonia. It is also encountered in typhus fever, in the third or fourth week of the disease; in the acute exanthems, especially in smallpox and scarlatina; in cholera; in pyæmia; often, also, in dysentery; and, finally, in tuberculosis and carcinoma.

Pustulous inflammation of the œsophageal mucous membrane occurs principally in the wake of the use of tartarized antimony; or else as one of the phenomena of variola. It is an exceedingly infrequent affection.

Ulcers of the œsophageal mucous membrane result either from the above-enumerated forms of inflammation, especially catarrh, or from traumatic injury, scalding, or the action of corrosive substances. Tuberculous ulcers are encountered very seldom, only; but cancerous ulcers are met with much more frequently.

The symptoms of inflammatory affections of the œsophagus are usually obscure. This is, in part, to be accounted for by the comparative insensitiveness of the organ. Chronic inflammations sometimes pursue their course without giving rise to a single characteristic symptom. Acute inflammations of moderate intensity, or of circumscribed extent, very often occasion only a dull pain beneath the sternum, a feeling of constriction, or a slight impediment to deglutition, and the discharge of a more or less viscid mucus. Vomiting seldom occurs in these cases, and usually only when the pharynx is over-irritated by the accumulations of viscid mucus. Even when the inflammation is severe, the symptoms are often so masked by the symptoms of some co-existing affection, as to divert the physician's attention from the condition of the œsophagus itself. Thus, croup of the œsophagus, which appears in the course of severe scarlatina or typhus, or in connection with croup of the larynx, is in most cases altogether latent.

In those cases, however, in which the inflammation of the œsophagus is idiopathic and acute, and of a certain extent and intensity; and also, it is not to be denied, in a large proportion of cases of secondary catarrhal or croupous inflammation, we find symptoms so characteristic that the disease of the œsophagus cannot be overlooked; and in most instances these symptoms indicate the correct diagnosis. The patients complain of a more or less severe pain in the course of the œsophagus, usually most painful beneath the manubrium sterni or in the pit of the stomach; less frequently between the shoulder-blades. This pain is increased by swallowing, especially of solids, and also by pressure from the outside, if the seat of disease be in the upper portion of the œsophagus. If the inflammation is sufficiently intense, the swelling of the mucous membrane may be so great as to constrict the calibre of the œsophagus to such an extent as to render deglutition not only difficult, but even impossible in marked cases; and repeated attempts to swallow will end in regurgitation, or even provoke vomiting, with the discharge of ingesta, as the case may be, and a greater or less admixture of sanguinolent mucus. Not infrequently a spasm of the œsophagus ensues on deglutition, and in most instances involves the respiratory organs, so that there is a sense of impending suffocation with intense dyspnœa.

It may be remarked, in passing, that it is not so much the swelling of the mucous membrane that impedes deglutition or renders it impossible, as the co-existent inflammation of the muscles, or, at least, their serous infiltration, which impairs their ability to grasp the bolus and propel it farther. The patient exhibits continual anxiety, and constantly complains of a great compression in the chest. Febrile phenomena supervene if the inflammation involves a large extent of surface, and, in isolated cases, may terminate in convulsions.

In the croupous inflammation, it often happens, in addition to the above-enumerated symptoms, that shreds of false membrane are hawked up or vomited,

as in the cases reported by Abercrombie, Winslow, J. Frank, Hennig, and others.

The termination of œsophagitis, if simply catarrhal and acute, is in recovery in a few days, or in chronic catarrh of the œsophagus. Pustulous inflammation following the use of tartarized antimony also terminates, usually, in recovery. Not so, however, where the pustulous inflammation is a manifestation of small-pox, or where croupous inflammation exists. Cases of these varieties usually terminate fatally. Cases of simple inflammation, but intense in character, involving not only the mucous membrane but the subjacent connective tissue also, and denominated "phlegmonous œsophagitis," sometimes terminate fatally within two or three days; or, if this period is passed, at a later date, from the partial or complete adherence of the walls of the œsophagus: in other cases abscesses form, which discharge internally, or externally, and leave a condition of stricture.

The treatment of acute œsophagitis does not require any special therapeutic measures, as a rule. If the inflammation is severe, the parts must be protected against further irritation, and efforts be made to allay that already existing. To this end the patient is forbidden to speak much, or to make much effort in swallowing. Fluid nutriment is given, and demulcent drinks are administered; the latter containing anodynes if required. Thirst is allayed by bits of ice allowed to melt in the mouth, by the sucking of orange-juice, or by rinsing the mouth frequently with acidulated water. Local depletion near the seat of pain is indicated only in cases where the pain is rather high up, and in which relief has not followed the external application of cold, or the subcutaneous injection of narcotics.

The cause of the œsophagitis, when discoverable, must be attended to. Foreign bodies must be extracted. Deglutition of concentrated acids must be treated by the administration of alkaline drinks. Caustic alkalies must be followed by acid drinks; the best of which, according to Orfila's experience, is a mixture of vinegar and water.

The treatment of chronic œsophagitis will depend greatly on the cause of the disease. Syphilitic inflammation is to be handled with antisyphilitic remedies. Disturbances of circulation require the use of digitalis, and of dilute mineral waters. The diet must be attended to; alcohol, and food of all kinds that is liable to produce irritation chemically or mechanically, must be interdicted, or used under certain restrictions commensurate with the degree of dysphagia and the irritability of the œsophageal mucous membrane.

Local treatment is called for, and consists usually in swabbing the diseased tissues with solutions of tannin, alum, iodine, or nitrate of silver; the article last named occupying the chief *rôle* in this connection. It is also recommended to cauterize the painful surface superficially with a weak solution of nitrate of silver as soon as there is reason to fear that the pain is due to the process of ulceration. In addition to this, counter-irritants are applied to the back of the neck, to the region over the dorsal vertebræ; steam-baths and warm plunge-baths are resorted to; and drinks of carbonic acid waters administered. The internal use of iodide of potassium has often been advantageous, especially in cases of circumscribed extent. If stenosis ensue as a result of chronic œsophagitis, it requires special surgical treatment.

After a patient has been relieved of an œsophagitis, even when only moderately intense, the physician should not neglect to advise occasional catheterization of the œsophagus for a period of at least two years; in order to avoid stenosis, on the one hand, or to detect it early, on the other.

Mycosis Septica in a New-born Child (Orth: quoted from *Centralblatt für Med. Wiss.*, No. 41, 1872).—At the post-mortem examination, three days and a half after birth, the author found in the right pleural cavity a large amount of flocculo-purulent exudation, which was in connection with an abscess as large as a cherry-stone, situated on the under edge of the inferior lobe of the lung. The superior lobe of the left lung contained a similar abscess of small size. An examination, thirty hours after death, of the fibrino-purulent matter found upon the surface of the right lung, showed that it consisted of masses composed of small, shining granules and pus-cells.

These collections, or colonies, as well as similar bodies on the pleural surface, were found to contain countless micrococci and small round cells. The abscesses in the lungs contained ordinary pus-cells, without any admixture of fungous elements. The entire parenchyma, however, as well as the cavity of the alveoli, bronchi, and vessels of the rest of the lung, were filled with a countless mass of these same fungi, with a slight admixture of white and red blood-cells. The kidneys and all the other organs were free from these bodies. The mucous membrane of the bladder, however, and the blood revealed the presence of these fungi. The umbilical cord and its vessels were intact. Although the examination was made so long after death, the existence of cold weather inclines the author to think that the presence of the micrococci dates from intra-uterine life, since the mother, before the birth of the child, had severe fever and suffered from a severe perimetritis. The author supposes that the fungi escaped from the blood of the mother into that of the child. Ponfick, in a notice of the case, says that the subsequent dissemination of these bodies through the organism of the child must be regarded as emanating from the abscess in the lung, for the filling of the pleural cavity, as above described, could not have arisen from the circulation, but from the abscesses in the lung.

A Case of Rupture of the Uterus and Escape of the Fœtus with its Appendages into the Peritoneal Cavity—Abdominal Section—Cure (Fourrier: *Bull. Général de Thérapeutique*, tome lxxxiii. liv. 3: quoted from *Centralblatt für Med. Wiss.*, No. 43, 1872).—This accident happened to a woman in her third pregnancy, who had a severe fall six weeks before the termination of gestation, and to whom, before the os had dilated, two grains of ergotine were given by an inexperienced midwife. The occurrence of the rupture was instantly felt; the diagnosis was rendered unmistakable by the presence of two tumors, which were readily recognized as the uterus and the fœtus. The symptoms were very grave, but were not those of general peritonitis. Fourrier made an incision fourteen inches long over the fœtus, on the outer side of the right rectus abdominis, came instantly upon the dead child, and, without any manipulations of the intestines, successfully performed detruncation. He was also able, without altering the surroundings, to remove the fœtus with all its appendages. The gangrenous shreds of peritoneum and clots of blood which filled the cavity were carefully removed, and the wound was partially closed by three sutures.

Convalescence occurred in sixty-two days. At first, disinfection and removal of the sloughing tissues were sources of care; later, a slight phlegmasia and a pyæmiform fever created some alarm. Obstinate constipation was a chief symptom for some time. At the time of publication of these notes the menstrual period had not returned, the uterus was somewhat enlarged, not completely immovable, and greatly inclined towards the left side.

PHILADELPHIA
MEDICAL TIMES.
A WEEKLY JOURNAL OF
MEDICAL AND SURGICAL SCIENCE.

The Philadelphia Medical Times is an independent journal, devoted to no ends or interests whatever but those common to all who cultivate the science of medicine. Its columns are open to all those who wish to express their views on any subject coming within its legitimate sphere.

We invite contributions, reports of cases, notes and queries, medical news, and whatever may tend to increase the value of our pages.

All communications must bear the name of the sender (whether the name is to be published or not), and should be addressed to Editor Philadelphia Medical Times, care of the Publishers.

PUBLISHED EVERY SATURDAY BY
J. B. LIPPINCOTT & CO.,
715 and 717 Market St., Philadelphia, and 25 Bond St., New York.

SATURDAY, FEBRUARY 8, 1873.

EDITORIAL.

WE are happy to announce that by an arrangement entered into with a gentleman in London, of high professional standing and well-known literary ability, we shall hereafter lay before our readers, every other week, a letter containing the cream of the professional and scientific news and gossip of that city.

THE "STEERAGE."

ATTENTION has many times been called, with more or less effect, to the abuses which exist on board of emigrant-vessels; and much legislation has been directed to the most desirable end of their correction. Personal observation has shown us that there is a real foundation for complaint, even on the best-managed lines; we can never forget some of the scenes we have witnessed in the "steerage." A great deal of the trouble is fairly to be charged to the low character of the persons who take passage in this way; but by no means can the whole blame be shifted from the owners and managers of the lines.

Our attention has recently been called to this matter by some excellent remarks in the *Public Ledger*, in reference to a published letter describing one of the late voyages of the steamer "Erin," of the London and New York line. The account, as condensed in that paper, speaks for itself better than any amount of generalizing on the subject could do; and we therefore transcribe it:

"The recent developments which lead to these remarks are contained in a letter published by Mr. J. P. McDonnell, of New York, who has just made a voyage from London, via Havre, to New York, in the steamship 'Erin.' His letter is published over his own name; it is entirely dispassionate in its tone; it states the facts without abuse, and even speaks words of personal kindness towards the principal officers of the ship. It is to the still existing scandalous abuses of the 'steerage,' as exemplified on board this particular ship, that he invites attention. The 'Erin' sailed from London for Havre, on her way to New York, at four o'clock, Thursday morning, December 5th. Her sailing-day was the preceding Saturday, November 30th. During these five days her London 'steerage' passengers, among whom were thirty women and children, were detained 'shivering in the cold in the disgustingly filthy Victoria Docks.' This in itself was a gross wrong; but, considering what came afterwards, it was a trifle. At Havre about eight hundred more passengers were taken on, making about eight hundred and fifty in all, and these, with the ship's company, made a total of about a thousand souls on board. There were not 'accommodations' on the ship for this number of people, and at Havre 'bunks' were hurriedly constructed for about three hundred on the 'main deck.' Some of these 'bunks' contained seven or eight persons—men, women, and children—in a space where, by right, there should have been only two persons. Before the close of the voyage, even these wretched 'accommodations' for the 'steerage' passengers were taken from them, and they were all—men, women, and children—stowed away on the 'damp and loose planks of the midships,' which had been used down to this time for the storage of coal, and from which the coal had been taken out to supply the boilers of the steamer during the voyage! After they had been thus stowed away in this 'coal-hole,' Mr. McDonnell says it 'looked like a huge sepulchre.' An American officer, who passed through our recent war, said that 'he never, during his entire career, witnessed a sight so truly pitiable.'

"The picture thus exhibited is by no means the worst in Mr. McDonnell's narrative, the details of some others being of a character that can only be presented by saying the 'accommodations' of the ship were disgusting to the senses, revolting to decency, and could not have failed to be detrimental to health. We pass now to some other matters in the letter. For the thousand souls on board there were but two doctors. Six persons died during the voyage, and one of these could get no medical treatment until the day he died. For all the 'steerage' women and children there was but one stewardess, and at the outset of the voyage there were but three regular stewards for all the rest of the passengers. The result of this was that, in serving out the food, the strong got 'more than their allowance, the weak got none at all.' By the contract, each passenger was entitled to two quarts of water, 'but found it difficult to get even one pint.' The potatoes furnished 'were black and soft as wet soap;' the meat was so

hard and bad that the 'most famished-looking refused to take it,' and the tea and coffee were 'disgustingly nauseous.' The ship itself was in bad condition; her decks were leaky, and the water rained down on the 'steerage;' her midships were not strong; and she leaked to the extent of 'from six to nine feet of water a day,' which the pumps had to discharge. The passengers were promised a sixteen-day voyage, and got in place of it a twenty-eight days' experience of these 'steerage accommodations,' during which the women and children had at no time any protection by means of screens, partitions, closets, or other privacies, which would have enabled them to observe the commonest decencies of life.

"This condensed recital gives but an inadequate idea of the condition of the 'steerage' aboard the steamship 'Erin,' as described by Mr. McDonnell, and it is sufficient to show, either that the laws are not executed, or that some additional chapters are needed to the voluminous legislation about passenger 'vessels propelled in whole or in part by steam.'"

We would be far from depreciating the efforts of the religious world for the reclamation of the heathen; but we would venture to suggest that, while "man's inhumanity to man" finds such illustration as this in the dealings of "Christian" owners of vessels with the unprotected emigrant, there is a field very near home which has not yet been brought to the highest pitch of cultivation. It would seem also as if the societies which advocate "warming the bits before putting them in the horses' mouths," and whose members have such pity for galled and lame animals, might pause a moment to think whether there are not nobler, higher, and more urgent claimants of their sympathies and their benevolent interposition.

NEW JOURNALS.

WE have upon our table two new medical periodicals,—one American, the other Irish.

The American is the *Archives of Scientific and Practical Medicine*, edited by Drs. Brown-Séquard and Seguin. Its typography is worthy of its valuable and interesting contents. The leading article —a report of a case of traumatic brachial neuralgia, treated by excision of the cords which go to form the brachial plexus, by Drs. Sands and Seguin—is illustrated by a very handsome lithographic plate. Among the other papers we note one by "Dr. Mary C. Putnam" on "the significance of the pulse in the forming stage of generalized puerperal peritonitis." Ability and judgment have evidently been exercised in the preparation of the translations, reviews, and summaries.

The *Irish Hospital Gazette* is intended to take "the place left vacant by the *Dublin Hospital Gazette*, the change of title being adopted to mark it specially as the organ of the profession at large throughout Ireland." The first number contains much excellent reading-matter and several woodcuts; the second is promised for the 15th of January, but we have not yet received it. We presume the subsequent issues are to be fortnightly.

CORRESPONDENCE.

MEDICAL TRAINING.

To the Editor of the Philadelphia Medical Times:

THERE is a notion in the mind of the medical public that, in spite of their continuous efforts to improve it, the system of education followed in the medical schools is still defective,—that a large portion of the numbers of gentlemen who graduate every year are not yet fairly qualified to practise medicine in any of its departments advantageously to their patients. Even among those whose natural endowments and scholastic acquirements are sufficient, there are many who, immediately after graduation, are incompetent to apply at the bedside what they have learned in the schools. Professional lectures carefully heard and text-books attentively read enable intelligent students to acquire knowledge of the principles and theories upon which the practice of the healing art depends. The average pupils of the medical schools of the day listen to the professors and read the text-books, not with a view to immediate professional practice, but to pass examinations. It is the fashion to regard this as paramount to every other consideration. To prepare for examination, to learn in a limited period of time to answer all questions that examiners are likely to ask, seems to be the chief object of all effort. In connection with the schools there are private lecturers or companies of lecturers, some of whom announce that their special business is to qualify candidates to pass certain examinations. Pupils who patronize them have their memories crammed full of answers to the probable and possible questions of the prospective examiners, only to be forgotten within a few weeks after passing the examinations for which they have been thus prepared.

Some of those who avail themselves of this kind of assistance perceive that if they make themselves masters of the subjects taught, they must necessarily be able to pass examinations upon them. Those who study for the sole purpose of acquiring knowledge with comparatively little thought about passing examinations, enter hospitals, and, being trained in them, become reliable practitioners, and ultimately distinguished members of the profession. In hospitals they learn that the successful practice of medicine consists largely in personal service to individuals, requiring manipulations of various kinds at almost every step,—manipulations

which must be often repeated before they can be skilfully executed.

The student resident in a hospital very soon finds that he was not taught in his school what to observe or how to note his observations or to report them, and that his hands are without instruction in the use of instruments of any kind. In a word, he finds that he was educated at the medical school, but not trained in any degree to apply his knowledge efficiently in relieving sick or wounded persons. He may have often witnessed at the clinics operations of frequent necessity performed so skilfully and readily that they seemed to him so easy of execution that any tyro might repeat them equally well. And yet, when called upon the first time to introduce a catheter, for instance, he is surprised at his want of success in doing what he has often seen done without any apparent difficulty. Indeed, even the well-educated graduate is not unfrequently at a loss when he first assumes the responsibility of treating a serious case of disease, through want of that kind of knowledge which is acquired in hospital training or in practice.

With a view to obviate the kind of deficiency alluded to, the British government has established, at the military hospital at Netley, a school for training newly-appointed assistant-surgeons of the army and navy in the details and routine of professional and official duties.

The present organization is as follows: Deputy Inspector-General T. Longmore, Professor of Military Surgery.

Deputy Inspector-General W. C. Maclean, M.D., Professor of Military Medicine.

E. A. Parkes, M.D., Professor of Military Hygiene.

W. Aitken, M.D., Professor of Pathology.

Staff-Surgeon John Dennis Macdonald, M.D., Professor of Naval Hygiene; and four assistant professors selected from the medical staff of the army.

As with us, candidates for admission into the medical staff of the army or navy submit to a competitive examination. Those who are successful are sent to Netley on probation for four or six months.

The candidate commences his career in the wards of the hospital under the supervision of the staff surgeon of the division. He is held responsible for the ventilation and general neatness of the ward, as well as for the keeping of the different books and papers. He is required to keep a case-book, which is examined at the end of the course, and marked according to professional and literary merit, attention to detail of regulations, neatness, etc.

Each candidate is supplied with a microscope and other necessary instruments for his exclusive use, for which he is held responsible. He has a closet for their preservation. He is exercised in microscopic examination of tissues and morbid specimens in the microscope room, and he is made practically familiar with processes followed in the analysis of air, drinking-water, food, soils, etc., in the laboratory. He has also the use of libraries, museums, etc. designed to aid him in his studies.

A detailed account of this school is given in a report to the Surgeon-General of the U.S. Navy, by Medical Inspector Edward Shippen, U.S. Navy, Fleet-Surgeon on the European station.

Surgeon-General James C. Palmer, U.S. Navy, in his annual report to the Secretary of the Navy, suggests that a similar school be established for training assistant-surgeons of the Navy of the United States, and, to enable him to commence it, asks an appropriation of $15,000, a moderate sum for a purpose so valuable.

The commencement of such an institution is desirable. Though a very long time may elapse before it may be compared in any respect with the school at Netley, it cannot fail to exert a very beneficial influence on the naval medical service of the United States, and thus indirectly contribute to the general efficiency of the navy. R.

MEDICAL OFFICERS FOR THE AMERICAN STEAMSHIP COMPANY.

To the Editor of the Philadelphia Medical Times:

As the time draws near for the completion of the vessels of this Company, the question of the selection of properly qualified medical officers presents itself to the Board of Directors. As to the importance of this question to the travelling public there can be no doubt in the minds of medical men. Whether the Board feels the responsibility imposed upon them in this respect is not so certain. Whilst they are exercising the greatest care in the selection of the captains, engineers, and other important executive officers, it is believed that those persons who can command the greatest personal influence will be appointed to the positions of surgeons. If this is correct, then the professional qualifications of the candidates become a secondary consideration.

I take the liberty of suggesting to the Board the propriety of submitting the candidates for the positions as surgeons to an examination, to be conducted by a Board of Examiners selected from the medical teachers of our city. Let the gentlemen who are to compose this Board be named by the Deans of the University and Jefferson Medical College.

The examination should be largely practical in character, and no candidate should be examined who has not had at least three years of experience in the practice of medicine and surgery.

In this way the Company will secure the services of competent medical officers, and the public will feel that at least one danger is removed in their travels upon the sea. M.

WARM.

Editor Philadelphia Medical Times:

Dear Sir:—I have received another note from my friend Simkins. On this occasion it was called forth by a very serious illness from which I suffered, caused, I have no doubt, by overwork during

the intense heat of last summer in taking care of my friend Simkins's patients:

"My dear Timkins:

"I have just heard of your serious illness. In view of the fact that the uncertainties of life are great, and that the position you now hold in —— Hospital *may* become vacant, I have thought it advisable to commence an active canvass for it. I write to ask as a favor (possibly your last) that you will send me a letter of introduction to the President of the Board of Trustees. You can also send such testimonials as you may think proper. If I secure your place, it will be my nineteenth.

"Yours, very affectionately,

"Simkins."

Whereas, Mr. Editor, I was cool towards my friend Simkins, I now entertain for him a warm affection.

Yours, respectfully,

Timkins.

PROCEEDINGS OF SOCIETIES.

PATHOLOGICAL SOCIETY OF PHILADELPHIA.

Thursday, January 9, 1873.

The President, Dr. J. H. Hutchinson, in the chair.

Dr. WILLIAM F. NORRIS presented the following specimens:

I. *Glioma of the retina, with numerous metastases.*

B. N., æt. two and a half years, was brought by his parents to the clinic of the University of Pennsylvania in October, 1870, with the statement that in the winter previous they had noticed a yellowish reflex from the right pupil. The right eye was slightly prominent, lid a little swollen but not reddened, the eyeball very tense (T_2), commencing opacities in the cornea, a small quantity of pus in the anterior chamber, the lens yellowish and so far opaque that nothing could be seen behind it.

The case having been recognized as one of glioma, enucleation of the eyeball was performed October 20, 1870. The wound healed rapidly, and in ten days the child returned to his home.

The eyeball was laid in Müller's fluid to harden, and, when a section was made of it, a tumor was seen filling the posterior half of the ball, the anterior portion being filled with pus. To the outer upper side of the ball was a tumor firmly adhering to the sclera, shaped as if moulded to it, about one-half inch in length by one-fourth of an inch in thickness; and from this another nodule, about the size of a large pea, projected still farther into the orbital tissues. The continuity of the sclerotica between the external and internal tumor was unbroken, it having been infiltrated by the tumor but not ruptured by it. A microscopic section of it showed the characteristic structure of glioma, —viz., numerous small round cells, with large nuclei and scanty protoplasm, imbedded in a finely granular material, each cell being about the size of the granules of the granular layers of the retina.

The child soon returned to the clinic with a button of granulations springing from the bottom of the conjunctival sac. This rapidly increased in size, and, having filled the orbit, projected from the eyelids as a flattened round mass nearly three inches in diameter. Sloughs now formed on the exterior surface of the mass, which separated and fell off, materially reducing its size and allowing the distended eyelids once more to close over it. It, however, soon repullulated.

About this period several lumps appeared on the child's head, and one at the angle of the jaw (left side). Two of these attained considerable size; one near the vertex being a flattened hemisphere about three inches by two in diameter, and the one at the angle of the jaw ulcerating into the cavity of the mouth and causing a constant fetid discharge.

The child, at first very irritable, became heavy and soporose, and died December 14, 1870.

The autopsy showed that the tumors on the outside of the cranium had sprung apparently from the periosteum, leaving, when forcibly pulled off, the bones bare and rough. On removing the calvarium, numerous flattened ovoid lumps were found between the dura mater and the bone, that membrane firmly adhering to them. Some of these were as large as half a walnut. Opposite them were corresponding depressions in the cerebral convolutions. The brain-substance at these points presented no trace of the gliomatous degeneration.

It was also seen that the tumor filling the right orbit had extended backwards through the sphenoidal fissure into the cranium, and, crossing over through the sella turcica, extended to the vicinity of the sphenoidal fissure of the left side.

The case is interesting clinically from its extreme malignancy, and the inefficiency of the operation undertaken at a period when the tumor has filled the ball and caused inflammation and greatly increased intra-ocular pressure, to arrest even temporarily the progress of the disease. Scleral tumors, if small and formed at the posterior surface of the ball, are not to be diagnosticated before enucleation. Having found them, according to many authorities, it is proper to destroy by cauterization the entire contents of the orbit; but the statistics of this procedure were not sufficiently encouraging to cause a decision in favor of so serious an operation.

The prognosis of all such tumors is eminently unfavorable, and the recorded cases in which the return has not been rapid are all instances in which the extirpation was undertaken early. In the foregoing example the yellow reflex from the eyeground had been observed by the parents for nearly a year before they considered it worth while to submit the child to medical examination.

The statistics of the subject have been carefully compiled by Hirschberg.* Out of seventy-seven cases he gives five cures (*i.e.*, 6.5 per cent.). One of these was observed seven years after the operation, one six, and in the other three from one to one and a quarter years had passed without a return of the disease. They were all operated on in the earliest stage of the disease.

I have reported the above history partly in the hope of inducing the members of the Society to use their influence to cause all such cases, as soon as observed, to be carefully examined with the ophthalmoscope, and, if the presence of an intra-ocular tumor be proved by it, to urge instant extirpation. Moreover, they will contribute essentially to the statistics of the subject if they will report the return or metastases of any such cases as fall under their notice. For here, if ever, we have a chance to prove the value of the knife in the treatment of malignant disease. By the ophthalmoscope the disease may be diagnosticated in its very incipiency; and while the abnormal mass measures only a millimetre or two in diameter, and while it is yet shut off from the rest of the organism by the firm fibrous capsule of the

* Der Markschwamm der Netzhaut, Berlin, 1869.

sclerotica, we have surely better means of deciding the question whether malignant disease can be eradicated by the knife, and, if not, whether life can be prolonged by the operation, than is presented to us in any other organ of the body.

II. *Sarcoma of the choroid.*

E. O'C., aged 60, presented herself at the clinic of the University of Pennsylvania, April 1, 1872, with a tumor of the right eye the size of a small hen's-egg. It was everywhere covered by conjunctiva, hard and nodulated. Some years previously an operation for staphyloma had been performed on the eye, and a section of the growth proved that it had its origin in the cicatrix of the shrunken ball.

Microscopic examination showed a network of very small spindle-cells closely felted together, and consequently a comparatively favorable prognosis was made. It was enucleated April 4, 1872, and up to the present date there has been no recurrence.

III. *Sarcoma of the choroid.*

J. H., æt. 25, a healthy-looking farmer, presented himself at the Wills Hospital with a hard lobulated tumor growing from the right eye and pushing the cornea upwards and outwards. The lids can still be closed over it; but it has grown much lately, and causes severe hemicrania. The ball and adherent tumor were removed May 5, 1872. A section of the ball showed the inner wall of it occupied by a *pigmented* tumor, which presented a mottled appearance, owing to some portions of it being less pigmented than others, while some were entirely uncolored. The retina, adherent to the tumor on that side, although pushed inward by it, was on the other side entirely detached from the choroid and separated from it by a mass of pus. The sclera was nowhere ruptured, but outside of it, opposite the choroidal tumor, was an unpigmented hemispherical mass about one-half of an inch in its longest diameter. Microscopic examination showed that the choroid tumor was a small spindle-celled sarcoma, some of the cells pigmented, some with a single nucleus, others with two or three. An examination of the episcleral growth and its edges showed that the fat tissue of the orbit had been irritated by the presence of the neighboring tumor; that the trabeculæ of fibrous tissue pervading it and bounding its areolæ had been hypertrophied, and that then the place occupied usually by the fat-cells had been infiltrated by a mass of small spindle and round cells, resembling those of the original tumor, except in their not being pigmented. This anatomical arrangement, of course, gives a marked areolar appearance to the tumor.

A most unfavorable prognosis was made, which has been only too accurately verified by the course of the case. Within a few days (*i.e.*, about seven months after the removal of the tumor) he has reappeared at the hospital with a recurrence of the growth *in situ*.

Dr. R. M. BERTOLET asked whether in pigmented sarcomata of the choroid, the metastases were also pigmented.

Dr. NORRIS replied that even with regard to sarcomata of the choroid, although the greater number were pigmented, certain tumors occurred which, notwithstanding the marked pigmentation of the mother tissue, were entirely composed of white cells. These are, however, rare. Dr. N. said that metastases were most frequent in the lungs and liver, and that some were pigmented and some not. This circumstance, he said, was claimed by the advocates of each of the two theories as supporting their own view. Those who believe in the metastasis of cells themselves consider the pigmented secondary deposits vindications of their theory; while those who believe in the constitutional origin of morbid growths affirm that their occurrence is evidence in favor of the view that the same cause produces the same effects even in different localities.

Dr. WM. H. BENNETT, for Dr. FRANCIS L. HAYNES, presented the specimens from a case of *intussusception* in an infant five months old.

Thos. M. R., a fine healthy infant, aged five months, was attacked with uncontrollable vomiting on December 25, 1872, at about nine o'clock P.M. The mother administered magnesia and various other remedies; but they were immediately rejected by the stomach. Finally, on the morning of the 27th, I was called in. I found that the child was naturally of a constipated habit, and that no passage had occurred since the evening of the 24th, and then a very insufficient one only. A slight discharge of bloody water had occurred from the bowels on the 25th and 26th. The secretion of urine had been diminished. Upon inspecting and percussing the abdomen, nothing abnormal was discovered, but on making firm pressure in the left lumbar region a cylindrical tumor reaching from the costal margin to the iliac crest, and apparently about one inch and a half in diameter, was found. On introducing the finger into the rectum, a tumor of soft velvety consistence was felt, and having in its centre an oval orifice surrounded by a prominent border. With the assistance of Drs. Knight and Bennett, I passed an elastic catheter up the rectum, and injected as much water as possible, but without any result. Opiates were now administered in small doses and pushed by night to the verge of narcotism, when they were discontinued.

28th, A.M.—The child was suspended by his heels, the tube of a stomach-pump was pushed up the rectum till its extremity could be felt in the descending colon, and forced injections of water made through it by means of a Davidson's syringe. No beneficial result ensued, the water being immediately rejected. Gastrotomy was now proposed. The parents consented, but the operation was not considered justifiable by the consulting physicians. The vomiting, which had continued without cessation until this morning, now ceased. A plentiful supply of milk and brandy was directed to be given to the child. Throughout the day the child suffered from slight paroxysms of pain. Excepting these, his illness was remarkable from the fact that there was an entire absence of apparent suffering. In the evening the measures resorted to in the morning were repeated, but no change was produced.

29th.—In the morning about one ounce and a half of thin dirty-brownish fluid was discharged from the bowels.

Throughout the day the powers of life gradually failed, and at seven o'clock in the evening the child expired.

Autopsy, twenty-two hours after death.—Body frozen, somewhat reduced in flesh. The abdominal cavity only was opened, and the specimen extracted which is now presented for the inspection of the Society.

The specimen was referred to the Committee on Morbid Growths, who reported:

"In Dr. Bennett's specimen of intussusception of the intestine, the invaginated part, measuring twenty-two inches, comprises the ascending and transverse portions of the colon. The cæcum seems to have been the starting-point of the invagination, which, being inverted and descending along the colon, drew after it several inches of the ileum with its mesenteric attachment. Between the two serous surfaces of entering and returning layer were found evidences of inflammatory thickening with slight adhesions."

(To be continued.)

A CALL DECLINED.—Prof. Max von Pettenkofer declines to leave Munich for Vienna, to the great disappointment of all connected with the school in the latter city.

REVIEWS AND BOOK NOTICES.

WÖHLER'S OUTLINES OF ORGANIC CHEMISTRY. By RUDOLPH FITTIG, Ph.D., Nat. Sci. D. Translated from the Eighth German Edition by IRA REMSEN, M.D., Ph. D., Professor of Chemistry in Williams College, Mass. Pp. 547. Philadelphia, Henry C. Lea, 1873.

The value of this work to the student of chemistry is undoubted, as indeed might be imagined from the reputation of its distinguished author, and the number of editions through which it has passed.

Beginning with a short account of those properties common to most organic compounds, and of certain of the terms commonly used in classifying and describing them, the author passes in review most of the very numerous compounds hitherto investigated, describing particularly the most typical and important in each group, but saying all that is necessary with regard to the others. To add to the value of the work in the eyes of the student of medicine, fifty pages at the end are devoted to those substances which could not be readily considered elsewhere, such as the bile, the blood, etc.

The American editor has prefixed a chapter on the constitution of chemical compounds, for the benefit of those who may not be familiar with the theories in accordance with which the book has been arranged.

GLEANINGS FROM OUR EXCHANGES.

THE DEATH OF NAPOLEON III. THE POST-MORTEM EXAMINATION—THE OFFICIAL REPORT.—The post-mortem examination of the ex-Emperor took place on the 10th inst. It was performed by Dr. Sanderson, in the presence of Sir William Gull, Dr. Conneau, Dr. le Baron Corvisart, Sir Henry Thompson, Mr. Clover, and Mr. Foster. The examination occupied upwards of two hours, and the following is the official report:

"The most important result of the examination was that the kidneys were found to be involved in the inflammatory effects produced by the irritation of the vesical calculus—which must have been in the bladder for several years—to a degree which was not suspected, and if it had been suspected could not have been ascertained.

"The disease of the kidneys was of two kinds. There was, on the one hand, dilatation of both ureters and of the pelves of both kidneys. On the left side the dilatation was excessive, and had given rise to atrophy of the glandular substance of the organ; on the other there was subacute inflammation of the uriniferous tubes, which was of more recent origin. The parts in the neighborhood of the bladder were in a healthy state; the mucous membrane of the bladder and prostatic urethra exhibited the signs of subacute inflammation, but not the slightest indication of injury. In the interior of the bladder was found a part of a calculus, the form of which indicated that half had been removed. Besides this there were two or three extremely small fragments, none of them larger than a hempseed. This half-calculus weighed about three-quarters of an ounce, and measured one-quarter of an inch by fifteen-sixteenths of an inch.

"There was no disease of the heart, nor of any other organ, excepting of the kidneys. The brain and its membranes were in a perfectly natural state. The blood was generally liquid, and contained only a very few small clots. No trace of obstruction by coagula could be found either in the venous system, in the heart, or in the pulmonary artery. Death took place by the failure of the circulation, and was attributable to the general constitutional state of the patient.

"The disease of the kidneys, of which this state was the expression, was of such a nature and so advanced that it would in any case have shortly determined a fatal result.

"(Signed by all present.)

J. BURDON SANDERSON, M.D.,
DR. CONNEAU,
DR. LE BARON CORVISART,
HENRY THOMPSON,
J. T. CLOVER,
JOHN FOSTER.

"CAMDEN PLACE, CHISELHURST, Jan. 10, 1873, 6.30 P.M."

Sir William Gull left Camden Place as soon as the necropsy was over, and was not present at the careful consideration and discussion of the facts which ensued by the other medical men assembled. He records a separate opinion on one point only,—the origin of the calculus,—in the following terms:

"I desire to express the opinion that the phosphate of lime calculus which formed the nucleus of the mass was the result of prior cystitis (catarrhus vesicæ), and not the cause of it. This nucleus was of uncertain duration, and may even have been more recent than supposed in the appended report. However this may be, it was encrusted by two distinct and more recent formations of crystalline phosphate. The inner incrustation around the amorphous phosphate of lime was dense, and separated from the outer incrustation by a looser cellular but crystalline deposit of triple phosphate. It seems, to my judgment, more in accordance with clinical experience to regard the cystitis as the prior lesion, and that, by extension, as is common in such cases, it affected subsequently the ureters and pelves of the kidneys. No doubt, in the later stages of the malady, the calculus became, by its formation and increase, an augmenting cause of lesions.

"The other facts and statements I entirely indorse.

"WILLIAM W. GULL, M.D.

"BROOK STREET, January 10, 1873."

THE SO-CALLED CORPORA AMYLACEA IN THE MEMBRANOUS SEMICIRCULAR CANALS OF MAN (A. Lucæ: *Virchow's Archiv*, Band 54, Heft 4, 1872).—In this article Prof. Lucæ reiterates his conviction that certain bodies found in the membranous semicircular canals of man are of a pathological nature and are peculiar to the adult human being.

These bodies are never found in the new-born child, but, according to Lucæ, are produced, in some instances, by local disturbances; in others they are the result of general systemic disease. The name *corpora amylacea* is still applied to these bodies by Lucæ, since their starchy nature is said to be proved by the characteristic reaction manifested by them in the presence of iodine. They are found in gray degeneration of the spinal cord, typhus and typhoid fever, tumor of the brain, tuberculosis, morbus Brightii, chronic ulcer of the stomach, and in cases where a disease of the ear—as, for example, otitis media—has been present up to the time of death.

These bodies are not found in the lower mammals, birds, fishes, or amphibia, according to all observers.

Prof. Rüdinger opposes Prof. Lucæ on all points save the last.

He says that the reason these bodies are found in the above-mentioned diseases is due to the fact that these diseases supply the anatomist with his material, and, as they are normal structures, they must necessarily be found in all adult subjects, and their occurrence in such cases is rather *post hoc* than *propter hoc*. Rüdinger considers them "papilliform prominences on the inner surface of the tunica propria of the membranous semicircular canal." And he adds, "I must consider them normal structures of the adult human being, since I have never failed to find them, in some stage of

development at least, in man. So far as their reaction with iodine is concerned, they share that characteristic with the tunica propria and other tissues in which no starch can be shown to exist; and, furthermore, the epithelium with which these bodies are covered, but the existence of which Lucæ has denied, can be readily shown by the proper application of the necessary reagents."

Concerning their function, Rüdinger says,—

"If we dare suppose that the membranous semicircular canals secern the endolymph, these papillæ would appear to be structures eminently calculated to supply a large secreting surface." C. H. B.

Doubtful Sex (Tardieu: quoted from *Centralblatt für Med. Wiss.*, No. 45, 1872).—In a memoir on the medico-legal aspect of cases of doubtful sex, the author relates the following: A man married a person whose genitals were not normally constructed. Although he soon discovered that the individual did not belong to the female sex, he did not attempt to institute a suit for divorce on the plea of invalidity of marriage. The person in question possessed no mammæ, and its pelvis was more like a man's than a woman's. There was no vagina, no uterus, no ovary, nor had there ever been (twenty-seven years) any menstrual flow of blood, nor any periodical pains: only the external genitals, in consequence of excessive hypospadias, could give the impression of appertaining to a female. Since, according to the French law, impotence or malformation of an individual of undoubted sex can be no impediment to marriage nor cause of divorce, and since, on the other hand, a marriage between persons of the same sex cannot be consummated, and where it may have occurred by accident is of itself null and void, the great question in this case was whether the person under consideration should be regarded as a woman with abnormally formed genitals, or whether *she* should be regarded as a man. The first trial decided the marriage to be illegal, on the latter alternative, after a careful medico-legal examination. The so-called wife appealed from this decision, and procured a medical certificate stating that she must be considered a female from the structure of the external genital organs. Finally Tardieu was called upon for his opinion, which was as follows. Since this person was not the possessor of the essential organs of a female, uterus and ovaries, said person cannot belong to the female sex; but, since similar cases show that persons with just such abnormal genitals are provided with testicles, though diminutive and hidden, therefore they must be regarded as belonging to the male sex. And the verdict was rendered accordingly.

MISCELLANY.

The late Mr. James Startin, F.R.C.S., was one of the leading dermatologists in London, and had a very large practice. His name was well known to the profession in this country some twenty years ago, from his advocacy of a so-called "immovable dressing" for fractures, his idea being to apply bandages and subsequently to stiffen them with stearine. The "paraffine bandage" now used by many English surgeons is very analogous to this.

It is stated that, on motion of the Earl of Derby, the residue of the fund raised for the sufferers by the cotton famine is to be applied to the foundation of a hospital at Manchester.

Death-Rate of Boston.—By the annual report of the State Board of Health, it appears that the mortality of Boston in 1872 has been unprecedented. The deaths in 1872 exceeded those of 1871 by 37 per cent., exclusive of those from smallpox, the increase of which has been 25 per cent.

Yellow Fever at Rio de Janeiro.—Telegraphic advices from Lisbon, dated January 28, announce that the mail steamship from Rio de Janeiro, on the 11th instant, brought intelligence that the yellow fever was raging in Rio at the date of her departure.

The *Lancet* of January 4 says, "Robin and Littré have submitted to the Academy of Sciences the new edition of their Dictionary of Medicine. Robin points out that the work is based on philosophical principles. Pathology he considers as a branch of biology which levies contributions on mathematics, chemistry, physics, and even social science and history. The Archbishop of Orleans has denounced the Dictionary as tending to lower man to the level of the brutes."

The History of Medicine (*Lancet*, Jan. 4).—Dr. Ollivier, Deputy Professor at the Faculty of Medicine of Paris, will this session lecture in the room of the lamented Dr. Daremberg. The introductory discourse of this talented member of the Faculty was published in *L'Union Médicale*, December 10 and 12, 1872. The lecturer, after paying a well-deserved tribute to his predecessor, showed how important it is for medical men to have some notions as to what has been done before them. This knowledge should be especially possessed by those who write on our art. Dr. Ollivier, as an illustration of this, quotes two examples,—one concerning the transformation of starch into glycose by the action of the saliva, supposed to be a modern discovery: whilst Verheyen mentions it very clearly in his "Supplementum Anatomicum," published in 1710, p. 113. Here is the text: "Ut verò certiùs experire vim fermentivam salivæ, accepi duas partes farinæ tritici, earum alteram subegi cum meâ salivâ alteram cum aquâ vulgari leniter calefactâ; cumque utramque massam tenuissem in blando calore duarum circiter horarum spatio, inveni illam, quæ cum humore salivali erat subacta, itâ fermentatam, ac si flores cerevisiæ fuissent additi; alteram verò quoad sensum non mutatam." The second example refers to the use of the thermometer in acute diseases,—a practice lately revived, and thought by some to be quite modern. De Haen, however, had already noticed, as is now frequently observed, that in the shivering stage of fever the temperature is, nevertheless, very high. He says, in his "Ratio Medendi," published in 1761, "Tempore frigoris humani intolerabilis, cum pulsu contractiore, minore, thermometrum signat octo graduas ultra calorem naturalem" (vol. i., second part, chap. x. p. 205). The eight degrees seem much; but this is owing to De Haen's belief that the column of mercury still rises when it has left the axilla. The lecturer then referred to what are called new diseases and extinct diseases, took an extended view of the epidemics of ancient

times, and concluded with remarks on cholera and syphilis viewed as epidemic complaints.

THE SALE OF DIPLOMAS.—The *American Chemist* for January, 1873, says, "In the *Literarischer Anzeiger* we notice an advertisement of this disgraceful business, which has been legally suppressed by the Legislature of Pennsylvania. The publishers of the above scientific periodical must be in a condition of great poverty, that they are so lost to a sense of honor as to receive such an advertisement. The commissioners of charities should give them their attention."

BARON STOCKMAR, for very many years an influential personage in European diplomacy, whose memoirs have recently been published in English, began life as a physician, and practised as a civil and military surgeon for six or seven years. His appointment as physician-in-ordinary to Prince Leopold gave him an introduction into court circles, where he played an important part, especially in England.

CHARITY HOSPITAL OF PHILADELPHIA.—Drs. Deal and Kollock have recently been elected to fill the department of Diseases of Women and Children at this institution. Dr. Barton has been transferred from the medical to the surgical staff.

UNSUCCESSFUL CANDIDATES.—After a recent examination of female teachers in Ohio, some of the unsuccessful candidates complained that injustice had been done them, whereupon the examiners were so cruel as to publish extracts from the papers written by the rejected applicants. The following are a few specimens of the answers: "The food is first masticated and then passes through the phalanx;" "Respiration is the sweating of the body;" "The chest is formed of two bones, the sternum and the spinal cord."

A FOREIGN vegetarian, who came to this country with the intention of introducing unbolted flour, has given it up as impracticable, because, as he asserts, the Americans give such little time to their meals that they bolt everything they eat.

APPOINTMENT.—Governor Hartranft has appointed Dr. W. A. Hoffman Port Physician for Philadelphia. Our very efficient Health Officer, Mr. John E. Addicks, will be retained in his position.

IT is stated that Miss Sophia Jex Blake, the head and front of the female aspirants for medical honors at the Edinburgh University, came up for examination recently, but failed to pass, or, in British student phrase, was "plucked."

PRESBYTERIAN HOSPITAL DISPENSARY.—The Trustees of the Presbyterian Hospital, desirous to extend their benefits to the poor of West Philadelphia, have established a dispensary on Thirty-ninth Street, below Powelton Avenue. They have appointed Dr. De F. Willard as Surgeon, and Dr. G. S. Gerhard as Physician, both of whom will hold clinics daily at half-past one o'clock P.M.

NOVEL CURRENCY.—The London *Chemist and Druggist* says, "An American friend assures us that in South Bend, Indiana, they use small packages of quinine for change. As everybody takes quinine, they look upon it the same as legal tender, and it passes off without difficulty."

M. LITTRÉ, the greatest of medical scholars, has completed his dictionary of the French language,—one of the most remarkable feats of the century. The work is especially rich in its etymology and definition of medico-scientific terms.

MORTALITY OF PHILADELPHIA.—The interments reported at the Health Office for the week ending February 1, 1873, were 333; 166 adults, and 167 minors. 12 were of bodies brought from the country; making the mortality of the city 321. Among the causes of death were:

Consumption of the Lungs	48
Other Diseases of the Respiratory Organs	56
Diseases of the Circulatory Apparatus	14
Diseases of the Brain and Nervous System	47
Diseases of the Digestive Apparatus	15
Zymotic Diseases (11 from Scarlet Fever)	27
Typhoid Fever	9
Casualties	8
Exposure	2
Cancer	6
Intemperance	4
Suicide	1
Debility (including "Inanition" and "Marasmus")	31
Still-born	26
Old Age	15

(The interments reported for the week ending February 3, 1872, were 437.)

THE meteorological record kept at the Pennsylvania Hospital was as follows:

	THERMOMETER. Max.	Min.	BAROMETER. (2 P.M.)
Jan. 26	32.5°	21.5°	30.33 in.
" 27	36.0	28.0	29.86 in. (Snow.)
" 28	41.0	20.0	30.20 in.
" 29	16.5	3.0	30.48 in.
" 30	17 0	2.0	30.35 in.
" 31	31.5	8.0	30.34 in.
Feb. 1	34.0	17.0	30.23 in.

The mean temperature of the month of January was 29.68°, or 1.15° lower than that of January, 1872 (30.83°); and yet the latter was noted as an unusually cold month.

OFFICIAL LIST

OF CHANGES OF STATIONS AND DUTIES OF OFFICERS OF THE MEDICAL DEPARTMENT U.S. ARMY, FROM JANUARY 21, 1873, TO JANUARY 27, 1873, INCLUSIVE.

MCMILLIN, THOMAS, ASSISTANT-SURGEON.—To accompany batteries of Fourth Artillery, under orders for field-service in Oregon. S. O. 5, Department of California, January 10, 1873.

WEISEL, D., ASSISTANT-SURGEON.—Assigned to duty at Fort Johnston, N.C. S. O. 14, Department of the South, January 22, 1873.

SATURDAY, FEBRUARY 15, 1873.

ORIGINAL LECTURES.

LECTURES

ON THE SURGERY OF THE NARES, LARYNX, AND TRACHEA.

BEING THE MÜTTER LECTURES FOR 1872.

Delivered before the College of Physicians of Philadelphia,

BY J. SOLIS COHEN, M.D.

Reported by R. M. BERTOLET, M.D.

(Continued from page 292.)

LECTURE III.

ACUTE LARYNGITIS.

ACUTE laryngitis, catarrhal laryngitis, or erythematous laryngitis, is an inflammation of the mucous membrane, sudden and severe in its onset, and generally of short duration. It often occurs as an idiopathic affection, brought on by sudden or unusual exposure to cold, especially in the feeble and convalescent individual; but it is much more frequently met with in the course of chronic tuberculous or syphilitic laryngitis, an acute laryngitis being superimposed upon the pre-existing chronic affection. It also occurs in typhus fever, in pyæmic fever, and in erysipelas. It may be induced by overstraining the voice, or by inhalation of irritant vapors, etc. The presence of a foreign body in the pharynx may give rise to it, or the incautious use of instruments within the cavity of the throat, whether for the purpose of diagnosis or for the extraction of foreign bodies. Sometimes it has followed the use of the epiglottic forceps; sometimes it has been induced by severe cauterization of the larynx, or even of the pharynx. The most frequent cause of acute laryngitis is of traumatic origin, such as the partial deglutition of caustic solutions or boiling water, the inhalation of steam, flame, or acrid substances; the inflammation of the larynx supervening immediately.

Acute laryngitis, if at all severe, is generally ushered in by a chill, followed by fever; sore throat being also one of the earliest symptoms. The pain in the larynx is severe, very often described as scratching or burning, and is usually increased for the time by coughing, protracted or loud speaking, or the access of cold air to the parts: with this there is tenderness upon pressure, and there is a feeling of constriction as though there were a foreign body within the larynx. There is reason to believe that this sense of constriction is occasionally due to a spasmodic condition of the adductor muscles of the glottis on the one hand, or to a paralyzed condition of its dilator muscles on the other. Dyspnœa and dysphagia are speedily manifested. The voice generally becomes hoarse, and its emission is often difficult and painful; the words being frequently interrupted by wheezing and prolonged efforts of inspiration, symptoms which are indicative of constriction, whether from spasm or mechanical impediment situated above the glottis. Sometimes there is paresis of the vocal cords, usually with complete patency of the entire glottis, due to the extension of the inflammation to the constrictor muscles; and then there is more or less dysphonia, or even aphonia, in consequence. The cough is hoarse, hollow, or brassy, like that of croup, and is generally accompanied by a slight expectoration of mucus. As the disease advances, the fever grows more intense, the severity of the local symptoms increases, the appearance of the patient is anxious, suffocative paroxysms of dyspnœa and of spasm of the glottis ensue, the face becomes cyanotic, and, unless speedy relief is afforded, death occurs from gradual suffocation and coma, or from veritable asphyxia. Although the actual amount of inflammatory action present may not be very great, yet the conformation of the parts involved is such that even a moderate amount of swelling of the mucous membrane of the larynx will often seriously interfere with the respiratory function; and it is this mechanical impediment to free respiration that constitutes the grave and serious lesion of this disease.

As a usual thing, the inflammation involves the entire larynx, but very often it is confined to its upper portion; sometimes it is restricted to some special locality, as the epiglottis, one or both ventricular bands, one or both vocal cords, one or both arytenoids, etc.; and occasionally there are seen points of erosion along the crest of the epiglottis, or even upon its laryngeal face, or upon the Santorinian eminences, or upon the vocal cords; but these manifestations are uncommon.

The secretion of mucus is generally slight in quantity, and is usually of a serous quality, viscid but thin. In some cases the secretion is quite viscid and adherent, and is expectorated with difficulty in small pellets, while in other cases there is no evidence of abnormal secretion. Sometimes the irritation extends along the mucous membrane of the trachea and bronchi, and we have the evidences of inflammation of these structures superadded to the special phenomena of laryngitis.

Acute laryngitis may be conveniently separated into two forms; one in which the inflammation is limited to the mucous membrane, and the other in which it extends into the sub-mucous connective tissue.

In the first form of laryngitis, the entire laryngeal mucous membrane is very red and very much infiltrated. The epiglottis is swollen out to three or four times its normal bulk, while the mucous membrane of the ary-epiglottic folds, Santorinian and arytenoid cartilages, and ventricular bands, and sometimes even that of the vocal cords, is similarly swollen; the swelling being either symmetrical, or limited to one side only. This swelling is sometimes so extensive as to leave only a very narrow passage for the air; it greatly impairs the motion of the parts, so that the glottis can no longer be fully dilated, and a speedy termination of the patient's life by suffocation is threatened.

The disease, unless fatal, continues from seven to

ten days; there are, however, cases recorded in which its entire course was run in less than twenty-four hours. In mild cases of this disease the acute phenomena of fever will be absent; there is little or no impediment to respiration and deglutition, but the pain is severe and the voice hoarse. Upon examination the laryngeal mucous membrane will be found to be congested and of a fiery red color.

A subacute laryngitis accompanies many cases of bronchitis, and not infrequently attends pulmonary phthisis and other affections of the lungs. Another variety of this form is one which involves the trachea to a greater or less extent,—properly a laryngo-tracheitis. This may be simply catarrhal; or it may be pseudo-membranous, under which circumstances it is known as croup.

In the second form of acute laryngitis we have greater swelling than in the preceding form, from serous infiltration into the sub-mucous connective tissue, and we have the symptoms and appearances of œdema of the larynx. The severity of the local phenomena does not bear any relation to the amount of the febrile derangement, which is much less than in laryngitis which is confined to the mucous membrane. On the other hand, the local symptoms are much more severe, and more imperatively require immediate relief.

In the treatment of acute laryngitis it is essential to arrive at a proper diagnosis at an early date, and to act promptly and efficiently, remembering that it is an acute affection, rendered more dangerous on account of the locality invaded than from the violence of its action, and that, for this reason, local treatment must take precedence of general. Here the laryngoscope will be found of the greatest service, both as a means of accurate diagnosis, and for the successful application of local measures.

General and local depletory measures are not applicable here as in inflammations elsewhere, because we dare not always wait for their action. In the milder cases, the external application of leeches, the use of salines, and the inhalation of atomized astringent solutions, such as alum or sulphate of zinc, will prove beneficial, with perfect rest of the organ and maintenance of an equable temperature. The use of warm drinks or other methods of inducing moderate diaphoresis may sometimes be advantageously seconded by the frequent exhibition of small doses of aconite. If the pain in the parts is severe, the watery extract of opium, or a small quantity of morphia, should be added to the inhalation; and if there is considerable disturbance of the nervous system, anodynes in efficient doses should be administered, by enema or hypodermically. Gibb and others recommend the local use of strong solutions of nitrate of silver or sulphate of zinc; but the lecturer had never seen the necessity for such treatment. In severer cases, especially where there is œdema, early scarification of the parts, or sometimes mere puncture, will be of immense service.

Where scarification cannot be resorted to, tracheotomy should be promptly performed, that the lungs may receive a due supply of air to enable the system to pass through the natural stages of the inflammatory process. This operation should be performed the very moment that the impediment to respiration becomes serious. If the opening of the trachea be postponed, the blood will become so thoroughly poisoned by carbonization that the patient will succumb in a few hours after having been relieved of the local symptoms, or he may linger on for a few days, relieved from the immediate dyspnœa, and perish ultimately from the effects of the congestion of the lungs or brain which has followed the prolonged difficulty of respiration.

Acute laryngitis usually subsides without leaving any traces of its presence. Sometimes, however, it declines into a chronic laryngitis, which in many instances is apt to prove ulcerative; occasionally it is the direct precursor of the formation of morbid growths within the larynx. At times, too, it is followed by paralysis of the vocal cords. In acute laryngitis of traumatic origin there is an element of complication, from the destruction of tissue which is produced by the accident. Ulceration of the mucous membrane itself does not often take place in idiopathic laryngitis. The cartilages are rarely affected in acute laryngitis. Laryngoscopic inspection occasionally shows that the seat of the inflammation is limited to special portions of the larynx, without any active participation of the adjacent structures. The terms epiglottitis, chorditis vocalis, arytenoiditis, meso-arytenoiditis, are often employed to designate the particular seat of the inflammation. These lesions are to be treated in the same manner as acute laryngitis of a mild type affecting the entire organ; but if great swelling or œdema is present, scarification is required.

A subacute catarrhal laryngitis sometimes protracts convalescence after the severe symptoms of the acute form have passed away: this is to be treated by repeated applications of moderately strong (20 grs. to ℥j) solutions of nitrate of silver or sulphate of copper, assisted, if need for it appear, by the internal or external use of iodine or of mercury.

ACUTE LARYNGITIS IN CHILDREN.

Acute laryngitis in children, even where the inflammatory processes are confined to the mucous membrane, is apt to be more severe than in the adult. This is in part due to the greater sensitiveness and delicacy of the parts themselves, but also doubtless, in a great measure, on account of the greater sensitiveness and greater excitability of the nervous system in children. Thus the phenomena of spasm, whether they be direct or reflex, are more severe in themselves, and, on account of the small size of the larynx, more dangerous in their results. The condition to be described, though in its local manifestations it has much in common with laryngismus stridulus, is to be discriminated from that affection, which is more closely a neurosis, and unattended with the phenomena of inflammation which characterize a veritable laryngitis.

The affection is sometimes ushered in suddenly; though there is reason to believe that some general or special cause has given origin to it, which is either concealed or has not attracted attention. In other

cases it is preceded by the phenomena of coryza, pharyngitis, or bronchitis, the symptoms of which may have been so trifling as to have caused no anxiety on the part of the nurse or parent.

Like laryngismus stridulus, and like croup, the phenomena of paroxysmal cough, with impeded, noisy, or stridulous respiration, which first excite alarm, occur at night, and frequently rouse the patient from sleep. During the paroxysms the face becomes flushed, the pulse accelerated, and the motions of the child exhibit restlessness or anxiety. After a period, variable in its duration, these phenomena subside, and the patient falls asleep. A recurrence of the attack may take place during the night, or not until the next day or the next night. In the interval there are symptoms of moderate febrile reaction; the respiration is free, but more or less sonorous; the voice is more or less hoarse, the cough more or less harsh and dry. Sometimes there is slight disturbance of the digestive organs, but usually the general health does not appear to suffer. In a few days the phenomena gradually subside, respiration becomes quieter, the cough less harsh and more moist, and the voice gradually regains its ordinary quality of tone. Sometimes the phenomena of spasm are slight or entirely wanting, and the febrile condition may be so slight as to give no evidence of its existence; at other times the spasmodic phenomena are excessive, and may threaten asphyxia, and the febrile reaction is very great.

Moderate general antiphlogistic treatment is usually sufficient to subdue the acute laryngitis of children, care being taken by due administration of nutriment, and, if necessary, by tonics or even alcoholic preparations, to keep up the strength of the patient as far as possible. The relaxing influence of the warm bath, and the inhalation of the steam from hot water, may often be resorted to with advantage.

There is no disposition here to the exudation of false membrane, and therefore no permanent impediment to respiration. Should, however, œdematous effusion take place, the existence of which can almost always be detected by a digital exploration, or should the element of spasm be so pronounced as to threaten suffocation, the operation of tracheotomy becomes necessary, as in the adult; though in the case of serous œdema the effusion could sometimes be discharged by rupturing the distended membrane with the finger-nail. Laryngoscopic examination in these cases is practicable only as the exception, and not as the rule.

(To be continued.)

CLINICAL LECTURE ON CHRONIC MYELITIS.

BY DR. H. C. WOOD, JR.

Delivered at the Philadelphia Hospital.

Reported by Dr. W. H. PARISH, Resident Physician.

GENTLEMEN,—Pathologically speaking, there are but two, or at most three, ordinary diseases of the substance proper of the spinal cord. Let us consider for a moment the anatomy of this nervous centre. We have the nerve-cells and nerve-tubules, and the trabeculæ or the fibrous tissue,—an arrangement somewhat analogous to that of hepatic cells and connective tissue. Of course in the spinal cord there are also blood-vessels and probably lymphatics. Each chronic disease is situated in the nerve-cells and tubules or in the connective tissue; the latter tissue being only a modification of that seen throughout the system. Under the microscope it presents a granular condition after having been hardened with alcohol or chromic acid, but during life is most probably largely an amorphous material, with nuclei and some cells,—the granulations seen in the ordinary preparations being produced by the reagents used for hardening. Two of the chronic diseases of the cord are inflammatory; one of these is an inflammation of the connective tissue, known as sclerosis of the spinal cord, and analogous to cirrhosis of the liver. In this the nuclei of the connective-tissue cells increase in number, the cells multiply by division, and thus, the neuroglia becoming increased in quantity, a pressure is produced upon the nerve-cells and nerve-tubules. The result of this pressure is the gradual atrophy of these nerve-structures. Moreover, there is an exudation into or around the walls of the blood-vessels, and, like exudative or cicatricial tissue, everywhere this exudation gradually contracts, and thus by degrees produces an obliteration of the blood-vessels.

The other form of inflammatory change results in spots or foci of softening, disseminated along the cord-substance. These spots vary in color from a reddish to a pale yellow, the colors being due to extravasation of blood, and their varying hues dependent upon the date of the extravasation. A microscopical examination of these spots shows us fatty, broken-down nerve-tubules and some nerve-cells which have undergone the same change. We also see a multiplication and a granular condition of the connective-tissue cells. There are also seen a large quantity of granular bodies, and sometimes pus-cells. The walls of the blood-vessels are also seen to be fatty. This process then is one of inflammatory softening; the softening varying with the stage of the process. The disease is gradual but steady in its course, and may last for years.

The third form of chronic spinal disease is not one of inflammation, but is a form of simple fatty degeneration, or what is generally known as "white softening."

If the anterior and lateral columns of the cord are the principal seat of either of these lesions, the motor functions are chiefly perturbed, and paralysis more or less complete, with or without other symptoms, results. An involvement of the posterior column would interfere with the functions of sensation. A diminution of sensation, wandering pains, and loss of muscular co-ordination are symptoms which go to make up locomotor ataxia,—a spinal disease, whose clinical history is characteristic, yet the pathology of which is simply that of sclerosis involving the posterior column. It is doubtful if the cause of chorea and paralysis agitans is to be looked for in any lesion of the spinal cord. Of course we have tumors, traumatic injuries, etc., more or less

destructive to the cord; but we cannot now speak of these.

To-day we have before us two patients apparently representing the two inflammatory chronic diseases of the cord. The one of whom we shall first speak is

Charles D., æt. 36 years, a native of Germany, by occupation a machinist; of temperate habits; not addicted to excessive venery, and with no syphilitic taint. The following history up to the date of his admission we gather from his own statements:

His father, brothers, and sisters were quite healthy. His mother, however, was of a nervous temperament, and was subject to attacks which seem to have been epilepsy or hysteria. His father's occupation was that of a manufacturer of leaden pipes, copper and brass utensils, etc. The patient never worked in the shop, but, as salesman, handled the different articles. At the age of twenty-one he left his father's employ and came to America. Here for a while he did work in a paint-factory, but, being seized with some nervous disorder, which, however, lasted but a few days, he entered a boiler-factory, where he worked on copper boilers for a few years. Afterwards he was employed to polish axes, in which process fine copper dust was used.

When about nineteen years of age, he was first attacked with abdominal cramps. These continued about two weeks, when they in a great measure disappeared. Then supervened muscular contractions, especially of the lower extremities. So forcible were these contractions that it required the strength of two men to hold the patient in bed. When unrestrained, his body would be jerked up one or two feet from the mattress. Throughout this attack the bowels were usually constipated. On only one occasion does there seem to have been loss of consciousness, and then for a few minutes only. He was restored to health in about three months, afterwards doing service in the Prussian army.

During the latter part of 1869, while in the St. Mary's Hospital, and convalescent from typhoid fever, there came on an attack apparently very similar to the present one, which disappeared in about eight months. After leaving that hospital he again entered a boiler-factory. During January of the present year (1872) he was in the Municipal Hospital with an attack of variola. On February 10, 1872, after being a few days out of the Municipal Hospital, he was admitted to this hospital suffering with acute laryngitis and albuminuria. The laryngitis was severe and quite obstinate. Constipation also existed. On April 1 the throat trouble had disappeared, and albumen was no longer present in the urine.

About the 1st of March the patient began to complain of cramps in the umbilical region; these lasted some eight or ten minutes, and occurred usually once or twice daily. Opium relieved these cramps, but did not prevent their return. During the night of the 22d of April he was suddenly seized with violent contractions of the abdominal muscles, especially of the recti. In three days these contractions had extended to the muscles of the right forearm and to the muscles of the lower extremities; more marked, however, in the right than in the left. Touching the chest or abdomen would bring on these contractions, or if present would increase their severity. The most sensitive point was directly over the xiphoid cartilage. Touching it would be quickly followed by jerkings both of the abdominal muscles and of those of the lower limb. These muscular spasms were so severe as to nearly throw the patient out of bed. They would occur during the waking as well as the sleeping hours, and were attended with pain in the lumbar spinal region. At times there were sensations as of ants crawling over him. In the muscles there were almost constant fibrillar contractions, which were much increased when the limbs were handled. The calf muscles were less affected than were those of the thigh. The fibrillar twitchings were more marked in the right than in the left lower limb. Both these extremities were quite rigid, but could be flexed or extended without pain by a strong exertion of the patient's will or by another's assistance. In the right forearm there were slight fibrillar twitchings, but in the left there were none. Prior to this attack he had been confined to the bed, but whether from nerve-exhaustion or because of the weakness incident to the precedent variola, laryngitis, and albuminuria, did not seem clear. The muscles of the lower limbs were somewhat emaciated. An interrupted electrical current applied to the right lower extremity produced such excessively violent contractions as to nearly throw him from the bed. When applied to the left extremity, musculo-contractility did not seem above par, but fibrillar twitchings would occur in the right lower limb, and to a slight extent in the left. No muscular jerkings, however, would be occasioned. There was decided loss of general sensation throughout all the affected portions. He had most of the time slight vertical headache, with some weakness of vision. Any endeavor to stand or walk would produce such jerkings as to render the attempt unavailing. He could sit up a little in a chair, but spent most of the time in bed. There were no passages from the bowels without the aid of active purgatives. Urination was normal.

During the earlier weeks of this attack, the patient took large doses of iodide of potassium without any apparent benefit. During a portion of May he had hypodermic injections of Fowler's solution without any effect. On May 12 he received a hypodermic of $\frac{1}{60}$ gr. of sulphate of atropia, which produced in two minutes sensations of dryness and constriction of the pharynx, and also relieved the muscular spasms for several hours. For several weeks afterwards, the patient received $\frac{1}{75}$ gr. of this drug hypodermically once daily, with the effect of diminishing the frequency and intensity of the muscular jerkings. For a few days this remedy was suspended and a continuous electrical current was passed along the spine. The contractions increased in intensity, and the atropia was resumed and again produced an amelioration. During the month of June a continuous current was passed daily along the spine, and the atropia was administered only at intervals of several days. The electricity did not produce muscular contractions as at first, and the only phenomena attending its use were the usual ones of a burning under the electrodes and a coppery taste in the mouth.

On July 1 the following was the man's general condition: the bowels remained generally constipated, but there was no difficulty in micturition. The muscular jerkings and fibrillar movements in the right lower extremity, though still present, were less marked. Both present to some extent in the left one. In both legs there was wasting of the muscles, but this was most decided in the left one. There was then almost constantly a pain in the left knee, and a numbness, with a feeling of "pins and needles" throughout that extremity. An induced current along the right limb brought on violent jerking. A mild current to the left limb produced slight action of its muscles, with choreic movements of those of the right leg. A stronger current to the left thigh produced repeated and excessively rapid general spasms of the muscles of the right limb, raising it entirely, and elevating the foot 240 times per minute. These jerkings continued for several minutes after the removal of the electrodes, and were accompanied with pain along the lumbar region. For a few days during July there seemed to be a decided improvement, and the patient could almost stand alone. On the 27th of that month, however, the muscular spasms suddenly returned with

great violence, and seemed to involve the muscles from the head down. Accompanying these spasms there were fierce darting pains in the hips and thighs, with intense aching pain in the lumbar region and severe pain in the posterior portion of the head. In a few days the severity of these symptoms diminished, and the jerkings became confined to the muscles of the lower half of the person and the right upper extremity. The use of electricity was suspended. The iodide of potassium and the bromide of potassium, five grains of each, were directed to be taken three times daily.

December 1, 1872.—Since the last date the last two remedies have been taken with occasional suspension. There has been no decided change in the symptoms. The muscular jerkings still persist, unless controlled by some remedy. The one that acts most satisfactorily is a hypodermic injection of sulphate of morphia gr. $\frac{1}{4}$ and sulphate of atropia gr. $\frac{1}{60}$ in combination, this being used once or twice daily. The emaciation of the lower extremities has increased, yet the patient can still sit in a chair. Constipation continues troublesome. The bladder and kidneys act well, the urine being normal.

What then, gentlemen, is the nature of the disease of this man's spinal cord? The symptoms resemble those of sclerosis. Remember that the change in the connective tissue is a slow one; that the atrophy of the nerve-structures and the obliteration of the blood-vessels come on slowly, and that hence the symptoms must gradually show themselves and gradually become more marked. If the anterior and lateral columns are affected, there will be in disturbed motility, evidences of excitement, congestion, and irritation of the cord, before the pressure is sufficient to produce paralysis; reflex action will become excessive; and muscular twitchings, with fibrillar movements, local spasms, and rigidity, supervene. Striking the muscles in this case quickly produces repeated clonic spasms, lasting, perhaps, for a few minutes; the application of an electrical current brings about these twitchings in a most marked manner. There are, besides, spontaneous contractions of the abdominal muscles, making the walls of that cavity firm and tense. Sometimes the muscular jerkings are so severe as to throw the patient out of bed. When the muscles are temporarily unexcited, extension and flexion are not accompanied with pain; a fact to be borne in mind in differentiating this affection from chronic spinal meningitis. In the latter disease the spasms partake more of a tonic nature, the muscles are more rigid, with occasional spasms, and movements are accompanied with pain in the muscles as well as in the back. In sclerosis pain in the back may accompany the spasms, but there is no severe pain in the muscles. In the man before us the anterior and lateral columns were first involved, and as the pressure increases paralysis will become more and more marked until complete. Slowly it seems to be extending to the posterior columns, and sensation is gradually becoming affected. The disease will probably extend up the cord until the medulla becomes involved, when death must result from disturbance of the roots of the phrenic and pneumogastric nerves.

The man states that he has had a similar attack before, and recovered. I do not know whether this is correct or not; but it is possible, although I never saw such a case, that in the early stages the diseased action in the cord may cease for a time, and great amelioration take place; an amelioration which is, however, only of a temporary nature.

The treatment of sclerosis of the cord, like that of cirrhosis of the liver, is most unsatisfactory. Various remedies have been faithfully used without any apparent positive benefit. The electrical current in this case did no good, and the iodide of potassium was used with the same result. The regular progress of this disease has not been materially affected by any treatment as yet proposed for it.

(To be continued.)

ORIGINAL COMMUNICATIONS.

CYST OF THE IRIS—REMOVED BY OPERATION.

(With a Lithographic Plate.)

BY GEORGE STRAWBRIDGE, M.D.,

Lecturer on Diseases of the Eye and Ear to the University of Pennsylvania, Ophthalmic Surgeon to the Presbyterian Hospital in Philadelphia, etc.

THE history of the case, as given by the patient, Mr. G., æt. 70, is, that one year ago an unusual watery condition of the left eye was noticed, which gradually increased, and especially so when encountering a strong light, which caused such a degree of lachrymation that vision was thereby seriously interfered with. The eye was also painful. A few months later, the sight of the eye had decreased to such an extent that reading or writing was impossible, while the lachrymation was so great that, on attempting to write with the aid of his right eye, the paper was as if sprinkled with water. The pain had increased, and was of a smarting, burning character. The right eye had also become sympathetically affected, so that the light caused him great annoyance; while the amount of use he derived from it was very limited.

At the time of my examination, one year from the commencement of his trouble, a perfectly transparent cyst was visible in the anterior chamber of the left eye (see Fig. 1), in its outer lower quarter, having a height of five millimetres, and at its base a breadth of eight millimetres, and oval in shape. Oblique illumination showed it to be clear fluid contained within a transparent membranous bag.

The iris, which could be distinctly seen through the body, was pushed backward, causing it to be deeply concave at that point, and of a much darker color, by reason of its black uveal layer being brought into view. The cyst filled up the space between the iris and cornea completely; and the cornea directly over it was slightly cloudy. The pupil remained round, with slight abnormal dilatation, while the crystalline lens had become cataractous. Congestion of the conjunctival and ciliary blood-vessels existed to a moderate degree. Tension of the eyeball was slightly increased, and any amount of pressure caused pain.

The patient found the pain and annoyance to the right eye to be so rapidly increasing that he readily submitted to the operation for its removal.

A puncture was made in the periphery of the cornea, just below its horizontal meridian, with a Graefe cataract-knife, which was then passed downwards in the anterior chamber (transfixing the cyst in its passage), and the counterpuncture made at a point three lines distant from the puncture, and the cut completed. The collapsed cyst was then seized with a small curved iris-forceps, and gentle traction used to effect its removal. It soon became evident that the cyst and iris were firmly bound together, and the greatest care was required to prevent separation of the entire iris. Its complete removal was finally accomplished, together with that of the underlying iris-tissue.

No complication followed, and the eye healed rapidly. Fig. 2 represents the eye eleven months after the operation. The pupil is drawn outwards and downwards towards the old corneal opacity, causing the change in its shape; the loss of iris by the operation is also seen. The condition of the cornea and lens shows no change. Tension of eyeball good; the patient is entirely free from any pain or discomfort in either eye, and is able to use his right eye in reading and other fine work at pleasure, and there is no sign of return of the cyst.

Examination of the cyst showed it to belong to that class having a delicate membranous wall with epithelial lining and clear fluid contents. It evidently originated in the iris.

Mr. Hulke,* in his admirable report on cysts in the iris, has collected the histories of twenty-one cases, reported by Tyrrell,† Wharton Jones,‡ Dixon,§ Guepin,‖ Bostells,¶ Graefe,** Wordsworth,†† Mackenzie,‡‡ Turner,§§ Combessir,‖‖ White Cooper,¶¶ Stoeber,*** Richard,††† Haynes Walton,‡‡‡ and Hulke.§§§ To these add one case published by Fischer,‖‖‖ one by Graefe,¶¶¶ one by Arlt,**** six by Mooren,†††† one by Wecker,‡‡‡‡ one by Knapp,§§§§ and the one now published, making a total of thirty-three cases published up to the present date.

In these cases the cysts were found in size from that of a small pea to one four lines in height. They also exhibited great variety in color, some having a glistening white appearance like a pearl or the tendon of a muscle, others of a more bluish cast, the remainder being brown, reddish brown, or opaque brown.

The cyst-wall in some cases was found to consist of a transparent membrane with epithelial lining, while in others it was thick and tough, like cartilage; and the researches of Bowman and others have proved that in a great number of cases the cyst-wall is formed by the rarefied tissue of the iris, and that the uveal pigment forms the epithelial covering of the inner wall of the cyst.

The cyst-contents may consist of a clear, limpid fluid, or they may be thick, opaque, and gelatinous, or they may be composed of epithelium, fatty matter, cholesterine, and hair, as in the case reported by Graefe.*

The origin of the cyst may be either in the iris, or in the ciliary bodies, or in the portion of iris-tissue involved in the sclero-corneal cicatrix.

In more than two-thirds of these cases the eye had sustained some previous injury, such as a penetrating corneal wound; and this suggested to Mr. Hulke the idea that in some instances the cyst may originate out of a portion of Descemet's membrane, which may have been torn away from the back of the cornea by the penetrating body and carried before it into the iris.

Wecker considers these cystic growths to be the result of sacculation of the iris, and the enclosed fluid to be the aqueous humor. The iris becomes attached to the posterior wall of the cornea (often after penetrating wounds of the cornea) in such a way that an opening is still left in the adherent parts, through which the aqueous humor enters, and this finally develops into a cyst. This would very well account for that class of cysts occurring in eyes which have previously suffered from irido-choroiditis with synechial formations, or where the sacculation has been produced by a penetrating wound; but in another variety of cases where the cyst has developed without any previous cause, Mr. Bowman's theory† is much more plausible,—namely, that they are due to a morbid collection of fluid between the iris and its uveal layer, and that the first formation of the fluid is attended with a swelling of the uvea backwards towards the suspensory ligament and the lens, but, as the contact of these resisting parts must very speedily arrest any further advance in that direction, the accumulating fluid next begins to push forward the proper tissue of the iris. The highly extensile fibres of the iris slowly yield, until in the course of months they bulge before this fluid, and finally come in contact with the cornea, and sometimes may cause the pupil to be thrown towards the opposite side or to be rolled in front of it. This view is also confirmed by microscopic examination, which shows that the cyst-wall is often to a great extent made up of distinct iris-tissue with the uveal pigment layer forming the inner epithelial covering. This theory would explain the occurrence of the cyst in the case now published.

Graefe insists that, in some instances at least, the cyst must be regarded as a new formation, and supports his view by a case of dermoid cyst of the iris which contained epidermis and hair with amorphous fat and cholesterine.

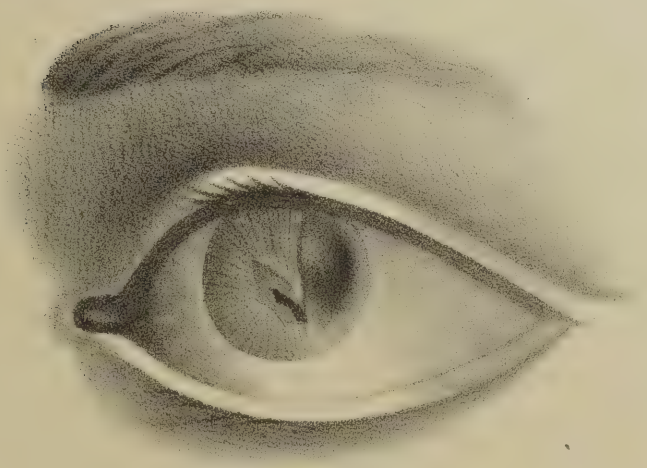
LARGE CYST OF IRIS.



EYE. - AFTER ITS REMOVAL.

DOUBLE LIFE SIZE.

As the histories of all cysts of the iris show that, if allowed to remain, they invariably become the cause of inflammatory action in the eyeball, in the form of a choroiditis or irido-choroiditis, with often sympathetic inflammation of the other eye, the indication is always to remove them as soon as possible before impairment of sight has occurred.

Puncture of the cyst has been repeatedly tried, but is so generally unsuccessful that excision is much to be preferred; although the latter operation is not unattended with risk.

A CASE OF POISONING BY STRYCHNIA—RECOVERY.

BY GERALD D. O'FARRELL, M.D.,
of Philadelphia.

ON the 22d of January I was called to see I. W., aged 50 years, a German baker. He had been drinking freely for a month past. A few days previous to my visit he had obtained from a drug-store in the vicinity two grains of strychnia, under pretence of wishing to poison a dog. He was rational, and admitted that he had taken the poison for the purpose, as he expressed it, "of spiting his wife."

I found him on a settee, his extremities cold and rigid, with so much subsultus tendinum that I was unable to feel any pulse; his face and body livid, the expression of his countenance hideous, and his respiration very difficult. He complained of intense pain in the pit of his stomach.

Ascertaining that the poison had been swallowed six hours, and that he had just before my arrival taken an emetic of sulphate of zinc sent him by the druggist from whom he had obtained the alkaloid, I could see no advantage to be derived from the use of the stomach-pump. There was slight emesis of a glairy white fluid slightly tinged with blood. I ordered him f℥i doses of chloroform every half-hour until relieved, and every hour after. I also gave him tannic acid in five-grain doses, frequently repeated, with large doses of animal charcoal at intervals. After the chloroform had been administered as above for eighteen hours, he slept; and when he awoke he expressed himself free from pain, but complained of being unable to stand, his limbs having no power to support him. The following day he was well and at his work.

NOTES OF HOSPITAL PRACTICE.

EPISCOPAL HOSPITAL.

CASE OF TETANUS, FOLLOWING BURNS, FATAL IN LESS THAN TWELVE HOURS.

Reported by LOUIS STARR, M.D., Resident Surgeon.

CHARLOTTE S., æt. 17 years, admitted to Dr. Packard's ward in the hospital, December 27, 1872, suffering with extensive burns, and a compound comminuted fracture of the right femur; caused by the explosion of the water-back of a kitchen range.

The burns were situated on back of neck and head, left shoulder and forearm, right forearm, left thigh and leg; the destruction of tissue being superficial, except in two places, one on the shoulder, the other on the thigh, where for an area of about two square inches it extended below the true skin.

The right femur was fractured at the junction of its middle and upper third; there were two wounds on the outside of the right thigh: the upper one, three inches in length, communicated with the bone at the seat of fracture; the lower wound, situated just above the knee-joint, was about an inch and a half long, and quite superficial. On admission, one day after receiving the injury, she complained of great pain, but her general condition was moderately good; there was little or no bleeding; her pulse was frequent, but strong; the temperature of the surface slightly raised, and a tendency to nausea.

The wounds in the right thigh were dressed with carbolic acid cerate, and weight extension applied to the leg; the burns with lard covered with cotton; and the patient was ordered a fever mixture, milk punch, and a milk and beef-tea diet. In the evening gr. ¼ of morphiæ sulph. was given by hypodermic injection.

December 28.—Condition slightly improved; less fever; pain in leg not so severe; stomach able to retain food.

December 29, 30, 31.—Condition still improving; pulse less frequent; sleeps moderately well; able to take some solid food; large but healthy discharge from wounds; treatment continued—gr. ¼ of morph. sulph. given each night by injection.

January 1, 1873.—[Dr. John Ashhurst, Jr., took charge of the ward.] Fever has subsided; complained of some pain in back of neck, which was entirely relieved on washing and redressing the burn situated there; fever mixture stopped; ordered iron and quinine; other treatment continued.

January 2.—Took through the day ♏ x ol. terebinth. in addition to the iron and quinine; at 6.30 P.M. felt rather more restless and uncomfortable than usual; f℥ij of liq. morph. sulph. were given by the mouth; passed an uncomfortable night.

January 3.—Pulse much more frequent, with a general febrile condition; tendency to diarrhœa; some slight twitching of muscles of arms and legs; turpentine mixture suspended, and f℥i of spt. eth. comp. ordered in its place. At 12 M., half an hour after taking the first dose of the anodyne, vomiting and purging came on; at 4 P.M. had taken three doses of spt. eth. comp. with no appreciable effect; spasmodic action of muscles still continued; face pale; skin hot and bathed in perspiration; at 4.30 she was seized with a well-marked convulsion, which lasted but a few minutes, when her jaws became locked, the muscles of the abdomen rigid, and the body arched backwards; in this condition she remained—with but a short interval, when the jaws were slightly relaxed—until the time of her death, at 6 P.M.

Several unsuccessful attempts were made to administer calabar bean.

THE *Druggists' Circular* gives the following as the formula for "juniper tar soap:"

℞ Oil of juniper, 1 fl. ounce,
Soft soap, 1 fl. ounce,
Alcohol, 1 fl. ounce. Mix.

The same journal answers a correspondent who asks if there is any varnish which will protect surgical instruments from rust, as follows: "There is; but we do not recommend it for such a purpose, though it is very useful to protect steel under other circumstances. Here it is: Melt common resin with a little Gallipoli oil and spirits of turpentine in proportions adapted to the particular case. The varnish should adhere firmly, not chip, and yet be easily removed. We have recently seen a mixture of carbolic acid and olive oil, recommended in an English paper; but paraffine dissolved in benzine is said to be still better. We do not think that the simple mercurial ointment can be much improved upon for delicate instruments."

PHILADELPHIA
MEDICAL TIMES.
A WEEKLY JOURNAL OF
MEDICAL AND SURGICAL SCIENCE.

The Philadelphia Medical Times is an independent journal, devoted to no ends or interests whatever but those common to all who cultivate the science of medicine. Its columns are open to all those who wish to express their views on any subject coming within its legitimate sphere.

We invite contributions, reports of cases, notes and queries, medical news, and whatever may tend to increase the value of our pages.

All communications must bear the name of the sender (whether the name is to be published or not), and should be addressed to Editor Philadelphia Medical Times, care of the Publishers.

PUBLISHED EVERY SATURDAY BY
J. B. LIPPINCOTT & CO.,
715 and 717 Market St., Philadelphia, and 25 Bond St., New York.

SATURDAY, FEBRUARY 15, 1873.

EDITORIAL.

THE PHARMACOPŒIA OF THE UNITED STATES.

THE new edition of the "United States Pharmacopœia," which within the last few days has issued from the press of J. B. Lippincott & Co., of this city, is a model of excellence in every respect, and does honor to all who have had any share in the work of its revision and publication. As a specimen of bookmaking, with its clear, sharp type, its general neatness, and its superior paper, it cannot be excelled by even the far-famed Riverside Press. But it is not merely as a fine specimen of typography that we are to look at this volume: it is one of the most valuable works published in this country. What Blackstone is to the lawyer, nay, even more, is the Pharmacopœia to the pharmaceutist, and through him to the physician and the community. The "Committee on Revision" has done its work faithfully and well.

Some may be inclined to find fault, some may say that this or that preparation might have been made more agreeable to the palate, or to the eye, in some other manner; perhaps so, but excellence gained in one way is often lost in another, and the efficiency of a drug is of much greater importance than its appearance or taste. The superiority of this edition to the preceding one is great, not only in the additions to the materia medica, but also in the introduction of several classes of preparations which are not to be found in any former edition, and in the weeding out of useless matter.

Upon opening the volume we find the "Proceedings of the National Convention of 1870," telling us of the appointment of the "Committee of Revision and Publication," which committee consists of some of the most honored men in the professions of medicine and pharmacy in this country.

Next comes the Preface, which gives us some insight into the immense amount of work the committee has performed.

Dr. G. B. Wood, in an introductory lecture delivered at the University of Pennsylvania, November 2, 1842, used the following words: "At this very moment, in the rage for novelty, we are threatened with an innovation in chemistry, which promises to subvert some of the facts of the science previously thought to be among those best settled, and to work an almost complete revolution in its nomenclature. The salts are no longer to be compounds of acids and metallic oxides, but of certain complex radicals with the metals themselves."

The "revolution in nomenclature" foreshadowed here has at last come upon us, and the new Pharmacopœia, "without adopting the new nomenclature of chemistry to its full extent," has adopted it to the extent necessary "to give uniformity; all the salts of the alkaline metals are designated as of the particular metal, not of its oxide." Though the new nomenclature may give us trouble at first, it certainly is a step in advance, and a step not prematurely taken. We fear it will take many a long day to unlearn and relearn the names of our old chemical friends.

The "Preliminary Notices" have not been altered from those of the last edition, and consist of notes on weights and measures, temperature, percolation, powders, etc.

The primary list of materia medica has been altered by the addition of twenty-four articles, among which we find carbolic acid, oxalate of cerium, chloral, iodoform, and other important drugs. Three articles have been added to the secondary list, and four dismissed from it, none of these being of much importance. We also find that the number of preparations has been increased by the addition of eighty-two new ones, while seven have been stricken off. Among the former, we notice many that bid fair to be of much use, and we are glad to welcome the new classes Chartæ, Glycerita, Suppositoria, and Succi.

The use of glycerin, and the lessening of the quantity of alcohol, in the fluid extracts, will meet the approval of those who are opposed to the use of the latter liquid.

A number of alterations of position and of

names have been made which need not be particularly mentioned here.

The last few pages of the volume are filled with several valuable tables of weights, measures, etc., ending with a copious index.

The history of the Pharmacopœia may not be familiar to all our readers, and to some a short sketch of its history and the sources of its authority may be interesting and instructive.

The first work on materia medica published in this country was the American Dispensatory of Dr. John Redman Coxe, which appeared in 1806. The Pharmacopœia of the Massachusetts Medical Society was published in 1808; this Pharmacopœia was also adopted by the Medical Society of New Hampshire. The next work on this subject was the American New Dispensatory of Dr. James Thacher, bearing the date 1810. In 1816 the Pharmacopœia of the New York Hospital was published, and the next year gave birth to Dr. Chapman's work on Materia Medica and Therapeutics. But the want of a national standard was still badly felt, for the difference in the preparations made according to different authorities created great confusion in regard to strength, dose, etc.

The first proposition to form a Pharmacopœia for Pennsylvania was made to the College of Physicians of Philadelphia on the 1st of May, 1787, by Dr. John Morgan; the proposition was not fully considered then, but was taken up again in 1789, and at several different times, until in 1797 the subject seems to have been dropped.

In 1817, Dr. Lyman Spalding, of New York, presented a plan for a National Pharmacopœia to the New York County Medical Society, and this society issued a circular calling for "the assembling of four district conventions severally composed of medical delegates from the Northern, Middle, Southern, and Western States." These conventions were each to compile a Pharmacopœia and to send delegates to a general convention. This general National Medical Convention assembled in the Capitol at Washington on the 1st of January, 1820, and was composed of delegates from the following societies: the Medical Societies of Vermont, New Hampshire, Massachusetts, Rhode Island, Connecticut, New Jersey, Delaware, Ohio, Indiana, South Carolina, Georgia, and the District of Columbia, and from Brown University, Yale College, the College of Physicians of Western New York, of the City of New York, and of Philadelphia, and from the Medical Convention of Maryland.

This convention formed the first Pharmacopœia of the United States, and provided for the assembling of a similar convention every ten years for the purpose of its revision.

The first edition of this work did not meet with general favor, and before the ten years had passed it was almost forgotten. But the importance of the subject and its practicability had interested in its favor some of the great lights of the medical profession. Dr. Samuel L. Mitchell presided at the first convention; Dr. Thomas T. Hewson was its secretary. Dr. Franklin Bache published a review of the first edition in the *American Recorder* in 1821.

In 1829 the College of Physicians of Philadelphia appointed a committee consisting of Dr. Hewson, Dr. Bache, and Dr. G. B. Wood; this committee prepared a Pharmacopœia, which was adopted by the college and afterwards by the national convention of 1830, and was published by the revising and publishing committee of that convention, after having been submitted to the Philadelphia College of Pharmacy and meeting with their approbation, in April, 1831. This edition was very generally accepted, and became the standard authority.

The convention of 1840 invited delegates from pharmaceutical colleges; and since that date these institutions have taken an active part in the preparation of the Pharmacopœia.

The first and second editions were published both in Latin and English. In the edition of 1840, and in the subsequent editions, the Latin language has not been used, except for the names of medicines and preparations.

Thus every ten years a convention composed of delegates from our most important medical and pharmaceutical societies meets at Washington to revise and republish the Pharmacopœia.

Among the names of those who have been influential and active in these conventions are many of whom Philadelphia may be proud,—Bache, Hewson, Wood, Carson, Bridges, Parrish, Procter, and many others. Our own College of Physicians has always been in the front rank of the workers in this good cause. F. A. H.

A NEW SANITARY "JOB."

WE see noticed in the daily papers a plan, which is said to have taken shape in a bill before the State Legislature, for a "Board of Sanitary Officers" for this city. The said Board, to be called the Street-cleaning Department, is to consist of six men named in the bill, who are to be placed in office until 1877, and are to have the entire charge of the removal of all dirt, garbage, dead animals, ashes, etc. They are to be clothed with

power to order the paving of streets when they think proper, and the bills for the work so done must be countersigned by the City Controller, and must be paid by the City Treasurer.

What checks are to be placed upon the six to insure their proper fulfilment of the duty of keeping the streets clean and well paved, and to prevent lavish expenditure of the public money by them for the benefit of contractors or hungry politicians. we do not know, not having seen the proposed bill.

But we do not think any man of average intellect can fail to see how a plan of this kind is likely to work. Certainly the six would have more than ordinary political virtue if they let slip the opportunities it would afford them of lining their own pockets at the expense of the public treasury. And he must be a simple-minded man indeed, who would look for clean or well-paved streets under such a system. On behalf of the sanitary interests of the city, we protest against this palpable "job." It would be far better to increase the powers of the Board of Health, and leave the matter in their hands.

LEADING ARTICLES.

THE HEALTH OF 1872.

IN looking over the reports of mortality of the past year, we find that the most remarkable phenomenon—more remarkable even than the epidemic of smallpox—was the increase of mortality caused by the excessive heat. The mortality in 1872 was greater from cholera infantum in the single month of July than ever before in the whole year.

The hottest summer of which any record has been kept was, until last year, that of 1870; and in 1870 the deaths from cholera infantum were 1002 in number. In 1872 the deaths from that cause amounted to 1666; 1080 of them in July, 324 in August, 143 in June, and 59 in September. 1221 of the deaths from cholera infantum were of children under one year,—more than one-fifth of the total mortality at that period of life, viz., 5862. 413 died from cholera infantum between the ages of one and two, and 32 between two and five.

But it was not only thus that the effect of the heat was shown. There were 136 deaths from sunstroke, to 11 the year before, and 52 in 1870,—the hottest summer previously known. Even in adults and independently of sunstroke was the effect of the heat shown. This is very unusual; for after the age of two we seldom or never before have seen the mortality increased by heat. But in the summer of 1872 the deaths in July were more numerous even among adults than in any other month except January alone, when smallpox was at its height.

In comparing thus the mortality caused by these two scourges of humanity, we find that in one respect they were analogous: both attacked children preferably. From smallpox about one-ninth of the mortality was in children under one year; from cholera infantum a much larger proportion, three-fourths of all the deaths being of children at that age. As regards duration, however, the two diseases were very different. Smallpox extended over a year, cholera infantum over the summer only; but during midsummer, and among children under one year, the mortality in July, when the hot weather was most intense, was nearly ten times as great from cholera infantum as ever in any one month from smallpox even at its height: so that in this respect it may be truly said that the mortality from cholera infantum was more remarkable than that from smallpox, although the total mortality in 1872 was only two-thirds as great.

PROCEEDINGS OF SOCIETIES.

PATHOLOGICAL SOCIETY OF PHILADELPHIA.

THURSDAY, JANUARY 9, 1873.

(Continued from p. 301.)

DR. J. EWING MEARS presented specimens of *uterus and both ovaries in a state of cystic degeneration, together with both kidneys, showing dilatation of their pelves.*

The specimens were removed from a patient of Dr. J. Ralston Wells, of Hestonville, whom Dr. Mears saw with Dr. Washington L. Atlee in April last. On that occasion Dr. Atlee tapped the patient, removing a bucketful of fluid from the abdominal cavity. This fluid was of a mixed character, the first portion evacuated being serous, then becoming sero-purulent, and finally changing into pus. At the time of the tapping the patient was suffering from an attack of acute peritonitis, the pulse was 130, small and wiry, the exhaustion was extreme, and death appeared imminent. Her condition was such that it was feared she would not survive the operation of tapping. With a view to relieve the dyspnœa which was produced by the accumulation of fluid in the abdominal cavity, and thus to render the patient more comfortable, the operation was performed.

Contrary to expectation, the patient recovered, not, however, without an extreme illness extending over seven weeks.
